PUBLISHED BY ROGERSON AND TUXFORD, 246, STRAND.

PRICE TWO SHILLINGS.

ROGERSON AND TUXFORD,] [PRINTERS, 246, STRAND.

THE ROYAL FARMERS'
AGRICULTURAL AND COMMERCIAL
INSURANCE COMPANY,

3, NORFOLK STREET, STRAND,

LONDON.

DIRECTORS.

Chairman.—STEPHEN C. DENISON, Esq. Deputy Judge Advocate, 35, Great George Street, Westminster, London.

Deputy Chairman.—B. P. SHEARER, Esq., Swanmore House, Bishop Waltham, Hants.

SAMUEL BOYDELL, Esq., 41, Queen Square, Bloomsbury, London.

NEWSON GARRETT, Esq., Alde House, Aldeburgh, Suffolk.

WILLIAM HODGES, Esq., Recorder of Poole, 1, Essex Court, Temple, London.

SAMUEL JONAS, Esq., Ickleton, Cambridgeshire.

Rev. HENRY E. KNATCHBULL, Elmham Vicarage, Thetford, Norfolk.

WILLIAM WILBERFORCE PEARSON, Esq., 27, Wimpole Street, London.

THOMAS ROLLS, Esq., Chipping Norton, Oxfordshire.

THOMAS SMITH, Esq., 36, Hart Street, Bloomsbury London.

GEORGE PARKER TUXFORD, Esq., 246, Strand, London.

THOMAS WATERS, Esq., Winchester, Hants.

FIRE INSURANCE on every description of property on terms as moderate as any other well-established Office.

NO CHARGE for New Fire Policies if for £300 and upwards, or if removed from other Offices to favour this Company.

HAIL INSURANCE.—The Bonus allowed in the year 1856 was upwards of 66 per cent. on insurance of five years' duration.

LOSSES promptly and liberally settled.

LIFE POLICIES payable to the Registered Holders, by which much inconvenience and expense is prevented.

BONUSES GUARANTEED, and therefore secured to the Assured, irrespective of the profits of the Office. Insurers in 1857 will be entitled to participate in the Bonus to be declared on the profits to the 31st of December, 1858.

NO CHARGE for Life Policy Stamps.

ADDITIONAL AGENTS WANTED. Application to be made to

JOHN REDDISH, Secretary and Actuary.

*** THE RENEWAL RECEIPTS for the Christmas Quarter are now in the hands of the Agents.

ESTABLISHED 1812.

TURNIP MANURE.—This valuable fertilizer has been used for the last twelve years with great success by most of the eminent Agriculturists throughout England, and stands unrivalled in the *weight* and *quality* of the bulbs which it produces; it is besides especially beneficial to the *Grain Crops* which follow, while *Clover* is rarely found to fail after the first application. Some of the crops produced by this Manure last year weighed upwards of Thirty Tons per acre. GRASS, BARLEY, CLOVER, and WHEAT MANURES; also BONE, GUANO, and SUPERPHOSPHATE of LIME, warranted of the best quality. Apply to—

H. & T. PROCTOR, CATHAY, BRISTOL.

PROCTOR & RYLAND { BIRMINGHAM, EDMONSCOTE, WARWICK, And SALTNEY, near CHESTER.

N.B.—A Pamphlet on "MANURES, their PROPERTIES and APPLICATION," forwarded on receipt of 12 postage stamps.

FARM ACCOUNTS.

Just published, in royal 8vo, bound in cloth, price 2s. 6d.,

A PRACTICAL SYSTEM OF FARM BOOKKEEPING; being that recommended in "The Book of the Farm," by Henry Stephens, F.R.S.E. Also, Folio ACCOUNT-BOOKS, constructed in accordance with the system, printed and ruled throughout; the whole being specially adapted for keeping, by an easy and accurate method, an account of all the transactions of the Farm.

"The great characteristic of this system is its simplicity. When once the details are mastered, which it will take very little trouble to accomplish, it will be prized as the clearest method to show the profit and loss of business, and to prove how the soundest and surest calculations can be arrived at. We earnestly recommend a trial of the entire series of books."—*Bell's Messenger.*

PORTRAIT OF MR. RICHARD HORNSBY.

PLATE II.

TWO LABOURERS' COTTAGES.

(For description see page 81.)

MR. RICHARD HORNSBY,

AGRICULTURAL ENGINEER, OF SPITTLEGATE WORKS, GRANTHAM, LINCOLNSHIRE.

If undeviating integrity, earnestness of intention, and a thorough knowledge of his profession should bring success, Mr. Hornsby has surely earned his reward. One is at a loss which to admire the more, the genuine straight-forward character of the man himself, or the excellence of those inventions with which his name is identified. But, after all, one is only the reflection of the other. We see in the good, sound, durable machinery that Hornsby and Sons send out, how the spirit of the master-mind has been employed upon them. From him the whole works take their tone. There shall be nothing here but what is honestly fitted for its purpose. Turning neither to the right nor the left, uninfluenced by any other consideration, the aim of the House has been to supply the farmer with those implements really best adapted for his use. This is now, and indeed has long been, well known; and we but echo the opinion of the whole country when we say, there are no people with whom a man can deal with more confidence than with the Hornsby's of Grantham.

This firm has now been established as that of Hornsby alone something like thirty years. It owes its origin and gradual development to the man whose portrait here occupies so worthy a place in our pages. Much as the business and repute of the house have increased of late years, under the careful direction of his eldest son, it was Richard Hornsby himself who not only commenced, but established it. Like many other good men before him, who have honestly risen to eminence, we trace him back to small beginnings—the road-side foundry—the master-man, busy at the forge—the gradual extension from one department to another until many hundreds have to look to him for their sustenance; and the town he entered a comparative stranger, points to him and his as its pride and boast.

The county, however, has an equal claim to him. Mr. Hornsby is both Lincolnshire born and bred. We have to go so far back as the summer of 1790 for the time of his birth—on rather a memorable day at that period, being no other than the fourth of June, the birth-day of good King George himself. The Hornsbys then farmed at Elsham, near Brigg, where the son continued until his fifteenth year. He was at best but a delicate boy; and, much against his friends' inclination, who would have preferred his adopting some less laborious pursuit, bound himself apprentice, in 1805, to Mr. Havercroft, a wheelwright at Barnetby-le-Wold. His new master shared the fears of his own relations as to his ever being able enough for such work, remarking, on first seeing him, that "he looked far more like filling a coffin than making one." The choice, however, was a good one. The pursuit agreed with him, and in five years' time he left Barnetby a hale, hearty man.

Mr. Hornsby turned his steps towards Grantham, where he quickly engaged himself with one Mr. Seaman, of the Spittle or Hospital Gate. The latter had discrimination enough to appreciate the value of his young workman. On the first of January, 1815, a business was opened under the title of "Seaman and Hornsby, Makers of Horse Thrashing Machines, &c., &c." The firm prospered, and in eleven years from this time we find Mr. Hornsby entering into a partnership of a yet more agreeable character. In a word, his marriage further settled him as a Grantham man, while but two years more found him with the works altogether under his own control. In the December of 1828, Mr. Seaman retired with a competency, and the business was known henceforth as that of Hornsby's solely.

The success of the House may be dated from this period. It was in Mr. Hornsby's hands that the trade gradually extended, and its repute proportionably increased. It was under his immediate

inspection that the machinery, for which they are still so famous, was first tried. It was with his imprimatur that the horse thrashing-machines* bowed to the power of steam; that the drills (first made here in 1815) were improved, and the dressing-machines were perfected. From this it is but an old story of well-merited distinction, with the old moral of going again to those who use you the best. Public and private experience have alike confirmed this; and the Hornsbys have never received a premium or an order but that they deserved it. Let their long ranges of workshops, and their hundreds of men in them, speak to the latter; while for the former we have some as readily available proof.

For their Improved Patent Portable Steam Engines they have been awarded:—

At the Imperial Royal Agricultural Society of Austria, at Vienna, May, 1857, the Gold Medal.

At the Hungarian Agricultural Society, at Pesth, June, 1857, the highest Diploma of Merit.

At the Universal Agricultural Exposition, Paris, 1856, the First Prize of £24 and Gold Medal, for the best Portable Steam Engine for Agricultural Purposes.

At the Universal Exposition at Paris, 1855, the Medal of Honour, for the best Portable Steam Engine.

At the Great Exhibition of the Industry of all Nations, held at the Crystal Palace, Hyde Park, London, July, 1851, for the best Portable Steam Engine for Agricultural Purposes, the First Prize or Council Medal.

For the Patent Combined Thrashing, Shaking, and Pressing Machine:

At the Universal Exposition at Paris, 1855, the Medal of Honour.

By the Royal Agricultural Society of England, at Carlisle, July, 1855, the First Prize of	20	0
By the North Lincolnshire Agricultural Society, at Boston, August, 1855, the First Prize of	5	0
By the Royal Agricultural Society of England, at Lincoln, July, 1854, the First Prize of	10	0
By the Selby and Tadcaster Agricultural Society, at Selby, July, 1854, the First Prize of	20	0
By the Herts Agricultural Society, at Hertford, October, 1854, the First Prize of	5	0
By the Northamptonshire Agricultural Society, at Oundle, Sept., 1853, the First Prize of	5	0
By the North Lincolnshire Agricultural Society, at Gainsborough, July, 1853, the First Prize of	5	0
By the North Lincolnshire Agricultural Society, at Horncastle, July, 1852, the First Prizes, amounting to	26	0
By the Great Yorkshire Agricultural Society, at Sheffield, August, 1852, the First Prize of	10	0
By the Highland Society of Scotland, at Glasgow, August, 1857, the First Prize of	10	0

For Patent Drills of every kind:—

By the Royal Agricultural Society of England, at Salisbury, July, 1857—		
For the best drill for general purposes	5	0
For the best turnip, seed, and manure drill	5	0
For the best corn drill	2	0

At the Universal Agricultural Exposition at Paris, June, 1856, for the best drill for general purposes, the First Prize of £10, and the Gold Medal; for the best corn and seed drill, the First Prize of £10, and the Gold Medal.

At the Universal Exposition at Paris, 1855, the Medal of Honour, for the best corn and seed drill, and for the best drill for general purposes.

At the Great Exhibition of the Industry of All Nations, held at the Crystal Palace, Hyde-park, London, 1851, for the best corn and seed drill, the Great Council Prize Medal; for the best turnip and manure drill for either ridges or flat ground, the Great Prize Medal.

For the best drop Drill for depositing turnip or mangold wurtzel seed at any required intervals, and in any given quantity, the Great Prize Medal.

By the Royal Agricultural Society of England at Carlisle, July, 1855:—	£	s.
For the best corn and seed Drill	10	0
For the best small occupation corn Drill	5	0
For the best turnip Drill with manure	5	0
By the Royal Agricultural Society of England, at Lincoln, July, 1854:—	£	s.
For the best Drill for general purposes	10	0
For the best corn and seed Drill	10	0
For the best turnip Drill, on the flat, with manure	5	0
For the best turnip Drill, on the ridge, with manure	5	0

* In 1830, the labourers of Lincolnshire conceived a violent dislike to these horse-thrashing machines, and traversed the country in mobs, destroying them. The farmers became much alarmed, and Mr. Hornsby's yards were filled with such implements, consigned by them to his care. His premises consequently became a mark for the rioters; but they were never attacked, as the men, having gained their point with the masters, went back to work with the flail. In a very short time they again revolted, or, rather, asked as a favour that the thrashing-machines might be brought back! From that day their use was everywhere recognised, until in turn they had to succumb to steam-power.

By the Royal Agricultural Society of England, at Gloucester, July, 1853:—

	£	s.
For the best corn and seed Drill, with R. H. and Son's patent fore-carriage steerage	10	0
For the best turnip and mangold wurtzel and manure Drill, on the ridge	10	0

By the Royal Agricultural Society of England, at Lewes, July, 1852:—

	£	s.
For the best Drill for general purposes	10	0
For the best corn and seed Drill	10	0
For the best turnip, mangold wurtzel, and manure Drill, on the flat	10	0
For the best turnip, mangold wurtzel, and manure Drill, on the ridge	10	0

By the Royal Agricultural Society of England, at Exeter, July, 1850:—

	£	s.
For the best corn and turnip Drill	10	0
For the best Drill for turnips and manure, on the flat.....	10	0
For the best Drill for turnips and manure, on the ridge	10	0

With other similar prizes at earlier meetings of the Royal Agricultural Society, as well as at the Yorkshire, West of England, and others.

For Corn-dressing Machines:

By the Yorkshire Agricultural Society, at Beverley, August, 1845, the Prize Medal.		
By the Lincolnshire Agricultural Society, at Sleaford, August, 1845.....	1	10

The firm has been also successful with cake crushers and chaff cutters; numbering in all about 200 money prizes, of about £1400 value, and 21 gold, silver, and bronze medal prizes. These include the Great Council medal at the Exhibition of the Industry of all Nations, London, 1851; the Grand Medal of Honour, at the Universal Exposition at Paris, 1855; three gold medals at the Universal Agricultural Exposition at Paris, 1856; the gold medal at the Imperial Royal Agricultural Society of Austria, at Vienna, 1857; and the gold medal at the Agricultural and Horticultural Society of Gers, at Condom, 1857.

In appropriate commentary on this legion of honours, we may avail ourselves of the following well-written description from the *Official Illustrated Guide to the Great Northern Railway*:—

"No visitor to Grantham should leave the town without visiting the immense manufactory of Messrs. Hornsby and Son, whose agricultural implements have gained for them a world-wide reputation. Those who inspected the rich collection of machinery devoted to farming purposes, at the Great Exhibition of 1851, will remember the encomiums awarded to the productions of this eminent firm. The wonderful development in this department of science, and the great demand for first-class articles, are partly exemplified in the history of Mr. R. Hornsby's career. Forty years ago this gentleman walked into Grantham,—without capital or friends, it is true; but endowed with a patience and determination which speedily placed him on the high road to success: his present position is entirely owing to the intelligence with which he has studied the requirements of agricultural interests, and to the encouragement he has given to inventions of great ability and convenience. The works of Messrs. Hornsby and Son possess an interest which all must acknowledge and appreciate. *The Turnery*, into which the visitor is ushered on his visit to this manufactory, will prepare him, in some measure, for the extensive operations of this firm. In the immense department for machinery are the corn-drill, successfully introduced by Mr. Hornsby in the early days of his career, and exhibited at the world's bazaar in 1851, where a 'council medal' was awarded for it. Five of these machines, each combining various excellencies, were then shown. The ten-rowed corn and *general purpose* drill is a 'highly finished machine, with an improvement patented by this firm, of India-rubber tubes for conducting the seed down to the channel made by the coulter, which is a valuable improvement upon the old plan of a series of cups, made of tin, working one within the other. This drill has also another improvement of two coulter bars, by which an equal pressure is obtained upon every

coulter, and the double-action lever enables the manure to be deposited to any depth, and covered up previous to the seed being deposited.' The visitor, in promenading through this great manufactory, will do well to notice the moveable steam engines, for which Messrs. Hornsby and Son received the preference at the Great Exhibition over all their competitors; and have taken the first prizes in twenty-one out of twenty-three public competitions. The services rendered to agriculture by this little machine are invaluable. The necessity of threshing corn under cover in barns is obviated by this steam engine, the rick now being threshed in the open air at once as it stands. 'Instead of three or more barns clustering round the homestead, a single building will now suffice for dressing corn and chaff-cutting.' Besides these, there are many uses to which the moveable steam engine may be applied. The winnowing machines of the same manufacturers elicited the following verdict of the Judges at the York Agricultural Meeting:—'Several machines,' they say, 'were tried, but could not get through the grain, shorts, straw, and chaff, as it came from the threshing machines, without being choked, or requiring much more time than Hornsby's, *which did its work well*, parting the whole into best corn, good tail, tail, whites, screenings, and chaff, at the rate of about fifteen quarters an hour, and dressing over the second time at the rate of about twenty quarters per hour, parting the whole into six parts, as before, in a workmanlike manner.' 'Such masterly mastication and digestion, making the contents of our supposed wheat rick, forty quarters, in five hours ready for market, must be appreciated by farmers.'

"The whole of the operations in this establishment are on a great scale, and will astonish the uninitiated visitor. The plant is estimated at £100,000. The number of hands employed is 500. There are rooms and yards for every department of implement manufacturing:—for carpenters' work; for testing engines; a smithy, with thirty forges; a lathe-room; draftsman's-room; four joiners' shops; sawing-room, with six saws at work: immense quantities of wood (oak) and iron lie about. The timber-yard contains a stock of an average worth of £6,000. Machines are here in readiness to be sent to all parts of the world, especially to New Zealand and Australia, Sweden, Austria, France, and South America."

It was only this last week that we ourselves had the pleasure of inspecting the works; but Christmas is a busy time in the Strand; and we can only offer our thanks to Mr. Measom and his Guide, for a description that has served us so well.

For the last few years declining health has prevented Mr. Hornsby taking any very active share in the business. He has, however, a worthy successor in his eldest son, who, with two younger brothers, now represent the firm. Under their good stewardship the trade has been still increasing, while the name, even in this age of competition, more than sustains its pristine repute. "A good name," says an old proverb, "is a precious ointment;" and that of Hornsby promises long to illustrate the adage.

THE FOOD OF DAIRY COWS.

BY CUTHBERT W. JOHNSON, ESQ., F.R.S.

The treatment of the cow in the early days of English husbandry was evidently of a very rough description. In times when the advantages derived from feeding her well at all seasons was utterly disregarded—when warmth and cleanliness were deemed to be, for her, useless luxuries—when she was only kept in good condition with the duration of the grass of her pastures—when hay and straw was her only winter sustenance—need we wonder, in such days, that her breeding was equally neglected, and her diseases ascribed to all kinds of imaginary causes, such as the influence of the witch or the shrew-mouse?

It is hardly more than two centuries since we first find our English agricultural writers giving any directions for the breeding of cows. It was about the year 1669, that old Worlidge gives, with commendations, his English translation of Virgil's advice to the breeder of oxen—directions which would rather startle a modern breeder. He says:

> "——whoe'er breeds,
> To choose well-bodye'd females must have care.
> Of the best shape the sour-lookt heifers are;
> Her head great, long her neck, and to her thigh,
> Down from her chin, her dewlaps dangling lye;
> Long-sided, all parts large, whom great feet bears,
> And under crooked horns her bristling ears;
> The whole cow fair, and visag'd like the male,
> Sweeping the ground with her long lushy tail."

The large-boned, coarse-looking cows were evidently in the highest favour with the farmers of those days; they perhaps were the best adapted to withstand the rough treatment they had then to endure. When the cows were ill, they assigned the origin of their complaints not to neglect or bad feeding, but if the disease was in the slightest degree uncommon, to very imaginary and evil causes. It was about the year 1596, that Leonard Mascal, of Plumstead, in Kent, gives evidence of what knowledge even a cattle-doctor possessed in those days; for he came to the farmer's aid in his book "On the Government of Cattle." In this book, amongst other equally wise observations, he gave them directions how "to know the difference between cattle bewitched, and other soreness." Then, with a similar credulity, the farmers of that time believed, it seems, that if a poor little shrew-mouse ran over their cow, it rendered her lame. So Mascal gravely propounds to them the following remedy:—"You shall have her to a briar growing at both ends, and draw the beast under it, and so she will recover." Then he proceeded to inform his reader that if the cow had the bloody flux, then "ye shall take a frog; cut off his left leg, and so put him alive in the beast's mouth," &c.

With such abounding ignorance, we may reasonably conclude what comfortless kind of home-

stead-yards and winter pastures must have existed in those days; and from the directions which ever and anon appear in the works of these early writers, it is evident that leaves, straw, and the young branches of trees were not very unfrequently the sole food on which the dairy cows had to subsist.

How refreshing it is, then, to turn from the barbarism of those days to the modern well-bred and carefully-tended herds of our time—to a period when the advantages of gentleness, skilful feeding, cleanliness, quiet, and warmth, are so generally understood! Take, for instance, the researches of Mr. Horsfall, of Burley, in Yorkshire, described in the recent number of the Journal of the Royal Agricultural Society; notice how, step by step, he shows the demands made upon the cow for her calf and her milk and the food necessary to meet that ensuing waste of her substance. To illustrate these practical questions, he experimented during rather more than 27 weeks upon six milch cows. During this time the food was weighed, its composition ascertained, and the disposal of that food traced (*Jour. Roy. Ag. Soc.*, vol. xviii. p. 156). The food these cows consumed during that period, and its composition, were as follows:—

	Per day.	Total weight of food given.	Albumen.	Starch.	Oil.	Fibre.	Minerals.
	lbs.	lbs.	lbs.	lbs.	lbs.	lbs.	lbs.
Meadow hay	56	10,715	990	4,257	287	2,933	953
Rape-cake	30	5,740	1,803	2,177	611	494	171
Malt-coombs	9	1,722	411	791	51	320	88
Bran	9	1,722	246	800	96	258	100
Beans	9	1,722	464	774	34	176	53
Green food	204	39,032	862	3,074	115	1,148	541
Oat-straw	50	9,566	287	3,066	100	4,526	428
Bean-straw	12	2,296	376	725	51	594	217
Total	379	72,515	5,439 = Nitrogen 888 lbs.	15,664	1,345	10,449	2,551

The constituents of this food could only be disposed of by these cows in either the milk they yielded, the perspiration they emitted, the flesh they acquired, or the excrement they voided.

Now in this time the production of milk by six cows averaged 14 quarts per day each for 27⅓ weeks = 16,072 quarts, which at 41 oz. per quart = 41,184 lbs.

	lbs.
When dry or free from moisture.....	5230
Butter in 16,072 quarts at 30 per 1000 =	1235
Casein „ „ 48.2 „ =	1977
Sugar of milk ..... =	1804
Minerals { Phosphate of lime 99 / Other..... 115 } =	214
	5230

And in the same time they gained in weight 500 lbs., which their owner calculated to be 300 lbs. as fat, and 200 lbs. as flesh. The excrement of these cows was then examined, which amounted to 88 lbs. a day. This was examined by Professor Way, who found in it per cent.:—

Moisture	84.85
Phosphoric acid	.39
Potash	.58
Soda.....	.22
Other substances.....	13.96
	100.

Nitrogen .41 = Ammonia .49

So that from these examinations it would appear that if the nitrogen in the food of these cows equalled 888, the disposal of this was as follows:—

In the casein	316.
„ Fibrin	7.35
„ Manure	414.
The remainder consumed in perspiration	150.65
	888.

The question as to the proportion of the food necessary to keep her in store condition, and the farther proportion required by her when yielding milk, did not escape Mr. Horsfall's attention. He takes for his starting point the established opinion of his district, that 20 lbs. of meadow hay suffice for the daily maintenance of a cow of fair size in store condition, a like result being obtained from 120 lbs. of turnips per day. The six cows then required during the 27 weeks, for their *maintenance* only:—

	Albuminous matter.	Oil.	Starch, &c.	Total weight.
Hay.. lbs.	2127	616	9130	22,960
Turnips..	2295	306	9100	137,760

The excess of the food given to them beyond this amount, then, was chiefly converted into milk, or meat, or the enrichment of the excreta. For the maintenance, then, of a fair-sized cow for one day in a normal state, the following elements seem adequate:—

				Mineral Ingredients.	
	Albumen.	Oil.	Starch,	Lime.	Phosphoric acid.
In 20 lbs. of hay..	1.85	.536	7.95	.90	1.11
120 „ turnips	1.98	.26	7.82	.97	1.9

"When cows are in milk, there occurs a much greater activity of the functions; they eat and

drink more, evacuate more excrement, and, in all probability, spend considerably more food in respiration. Whilst the 17.60 lbs. per day dry matter in 20 lbs. of hay are found adequate for the maintenance of a cow in a store state, the six cows in milk have eaten on the average 21.37 lbs. solid matter per day during the 27⅓ weeks. When I have fattened cattle together with a number of milch cows of similar size, which gave on an average 8 quarts of milk per day, the whole being fed with moist steamed food, and receiving the same allowance of green food, I have found the fattening cattle refuse water, whilst the milk cows on the average drank upwards of 40 lbs. per day of water given separately. The 8 quarts of milk contain only about 17.58 lbs. of water; still in several analyses of excrement I have noticed little difference in the percentage of moisture in that from the fattening animals as compared with that from cows giving milk.

"These facts would seem to show that upwards of 20 lbs. more water were given off from the lungs and pores of the skin of a milking than of a fattening animal."

Another branch of the inquiry of the greatest practical value is the comparative real value of the dung of oxen when kept on different kinds of food. In elucidation of this most important inquiry, we have here two experiments of Mr. Horsfall, and two analyses by Mr. Way. These were made with eight cattle, the experiment being commenced in March, 1855. Mr. Horsfall tells us that "for the first six weeks after they were tied up, their food consisted of chopped straw, shells of oats, and bean straw in about equal proportions; 4 lbs. of rape-cake, 1 lb. bean-meal, ½ lb. linseed, and ½ lb. wheat ground together, and 30 lbs. swedes per day. The straw, &c., were cooked by steaming. On this food two of the heifers had gained 9 lbs. each in the month's weighing, the others 16 lbs. and 18 lbs. each per week; the average being somewhat more than 14 lbs. per week. A sample of the excrement was sent on the 26th of March to Professor Way for analyses. It contained:—

Moisture	83.81 lbs.
Organic matter	13.44
Sand, &c.	.93
Phosphate of lime	.64
Common salt	.18
Sulphate of soda and potash	.95
	99.95

Nitrogen .51 = ammonia .62.

"The yield of excrement is at the rate of about 9½ tons per year; value, 8s. 6d. per ton; or 1s. 7d. per week for each.

"My store of turnips being exhausted with March, an additional proportion of bean-straw, with the above-mentioned allowance of rape-cake, bean-meal, linseed, and wheat ground together, was supplied till the 24th of May, when a portion of meadow-grass was mixed with the straw, and by degrees the straw was discontinued; when mown grass, together with the same allowance of extra food, was given till the close of June, when the lot were of prime quality, and sold for the top market price. Up to the close of May their gain averaged over 14 lbs. per week; during June they gained something less than 14 lbs. per week. On the 29th of June a sample of excrement was sent to Professor Way, who reported its contents:—

Moisture	84.90 lbs.
Organic matter	11.94
Sand	.86
Phosphate of lime	1.33
Common salt	.24
Sulphate of soda and potash	.76
	100.00

Nitrogen .94 = 1.14 ammonia.

"The yield of excrement was at the rate of 9½ tons per year, and its value in ammonia and phosphate of lime may be computed at 15s. per ton, being at the rate of 2s. 10½d. per week for each, to which the sulphate of potash will be an appreciable addition."

It is impossible to assign an adequate value to inquiries such as these; they will lead to other and still more minute investigations as to the chemistry of food—a subject whose importance has only of late years been felt by the practical farmer. Great indeed, although slow, have been the advances made in this way since those days of the witches and the shrew-mouse to which I have referred, and the present time. And if we take the experience of the last two centuries as our guide, there appears little chance of the advancing progress of agriculture being stayed. The advance made only in the present century, in the breeding and rearing of our live stock, indicates this. Few farmers now survive who remember the times of Francis Duke of Bedford, and the institution in 1798 of the Smithfield Club; but we may learn from other sources of information the fact that what was then deemed perfection in the breed and management of our live stock, would be now little regarded by the present and-far-better-informed race of England's agriculturists.

THE LONDON, OR CENTRAL FARMERS' CLUB.

THE MECHANICAL AND CHEMICAL PRINCIPLES APPLICABLE TO DRAINAGE.

THE NESBIT TESTIMONIAL.

The concluding meeting for the present year, took place at the Club House, Bridge-street, Blackfriars, on Monday evening, December 7.

Mr. Owen Wallis presided, supported by a very large attendance of members, and subscribers to the Nesbit Testimonial. Amongst others present were Messrs. R. Baker, W. Bennett Joseph Pain, Rev. T. C. James, W. Bullock Webster, T. Hatfield, J. J. Mechi, T. E. Pawlett, J. Thomas (Bletsoe), J. Thomas (Lidlington), J. B. Spearing, L. A. Coussmaker, H. Shotter, J. Grove, G. Wilshir, J. Marshall, T. Chandler, T. Congreve, B. E. Ward, S. Sidney, C. Stokes, J. Tyler, W. Gray, G. P. Tuxford, J. Bailey Denton, C. M. Bidwell, J. Wood (Sussex), J. Wood (Croydon), J. Brown, W. Brown. J. Ploughman, W. Shaw (Coton), J. Smith (Rye), J. A. Yowl,

J. G. King, C. J. Morton, T. Scott, C. Howard (Beds), T. Twitchell, E. H. Bentall, C. J. Brickwell, G. H. Ramsay, R. de Trehonnais, W. Cheffins, J. Wells (Yorkshire), G. S. Harrison, S. Skelton, G. Hammond, W. Eve, J. Parkinson, &c., &c.

The subject for discussion, entrusted to Mr. J. C. Nesbit to introduce, was put on the card in the following terms: "The Mechanical and Chemical Principles which should properly regulate the Practice of Drainage."

On the table, in front of the Chairman, were placed a service of silver plate and a microscope, purchased by the promoters of the fund raised for the purpose of presenting a testimonial to Mr. Nesbit, for the services which he has rendered to the cause of agriculture. The service of plate—which whether for beauty of design or excellence of workmanship has not often been excelled by testimonials of a similar character—consisted of the following: A tea and coffee service, a very large salver, two smaller salvers, a cake-basket, an egg-frame, a butter-cooler, four tankards, a mahogany case containing twelve pairs of silver and dessert knives and forks with carved pearl handles, and about a hundred spoons and forks. The whole was supplied by Mr. Durrant, of No. 40, Cheapside. On the principal salver is engraved the following inscription, explanatory of the object of the presentation:—

"*Presented, together with a Service of Plate and a Microscope,*
to
Mr. J. C. NESBIT, F. C. S., &c., &c.,
Principal of the Agricultural and Chemical College, Kennington,
By Members of the Central Farmers' Club, and others interested in the Cultivation of the Soil,
In appreciation of the valuable services rendered by him to the Cause of Agriculture.
December 7th, 1857."

It may be added that the microscope, by Ross, was an admirable specimen of that species of instrument, and powerful enough to admit of the reading of the sixty-thousandth part of an inch.

The CHAIRMAN in opening the proceedings said—Gentlemen, before we go to the discussion of the evening, I have a very agreeable and pleasing duty to perform on your behalf, namely, that of presenting to Mr. Nesbit the handsome testimonial which you see on the table, as a mark of our appreciation of the services rendered by him to the agricultural community of this country (cheers). Mr. Nesbit has, as you are aware, on several occasions introduced discussions in this room, of a most valuable and instructive character; and whenever he has been amongst us he has answered any questions which may have been put to him, relative to agricultural subjects, most unreservedly and kindly (renewed cheers). Neither have his services been confined to the members of this club. I believe there is scarcely an agricultural club of any importance in the country, which has not availed itself of the same source of information, and all have, no doubt, profited by the instruction afforded to them. At the close of the last discussion which was introduced here by Mr. Nesbit—it was, I think, in April last year—it occurred to several members of the club that the time had come when the acknowledgment of the services thus rendered should assume some more substantial form than the customary and matter-of-course one of a vote of thanks. It was suggested that a subscription should be set on foot, with the view of purchasing a suitable testimonial; and this suggestion was immediately acted upon (cheers). Although the design originated with members of this club, it was hoped that the subscription would not be confined to them, and I am happy to say that that hope has not been disappointed (Hear, hear). The very handsome sum of £280 has been collected throughout the country on account of the Testimonial Fund. Of this sum I believe about £12 has been disbursed in defraying unavoidable expenses: the remainder has been expended in purchasing the very handsome and useful service of plate, and the very beautiful and powerful microscope, which are now on the table. This testimonial appears to me the more gratifying because it is an additional proof to the many which we have happily seen in the present age, that Science is no longer looked upon with doubt and distrust (Hear, hear), but is generally recognized as the handmaid of Practice, and its safest and surest guide. (Hear, hear.) Gentlemen, I will not take up any more of your time, knowing that many of you are anxious to visit Baker-street in the course of this evening, and knowing, too, that you are all desirous of hearing the remarks which Mr. Nesbit has to make in introducing the approaching discussion. I will now, with your permission, therefore, in the name and on behalf of the numerous subscribers to this handsome testimonial, request Mr. Nesbit's acceptance of it, as a mark of our good will and grateful feelings towards him; only adding the expression of a sincere hope that he may be enabled to enjoy what is now presented to him, and that his life may long be spared, not only for the sake of his family and friends, but also that he may continue to labour in the great field of science (loud cheers).

Mr. NESBIT, who on rising was very cordially received, spoke as follows: Mr. Chairman and gentlemen, I assure you it is with very considerable difficulty that I can even attempt to tell you how deeply I appreciate the kind and munificent present which you have bestowed upon me this evening. I accept it as a sign that the farmers of this country no longer think that science can be of no assistance to them, but are disposed to take science as an aid by which the art of agriculture may be improved (Hear, hear). Although, as a mark of personal respect for myself, I receive this testimonial with as strong a feeling of gratification as any man could possibly entertain under similar circumstances, and although I cherish a feeling of deep gratitude to those friends who have come forward to express their opinion as to the humble services which I have rendered to the cause of agriculture, I yet assign to this testimonial a much higher meaning than that; I regard it as a testimonial from the agricultural public to the scientific body. I view it not merely as an acknowledgment of services which I myself may have rendered, but also as a recognition on the part of agriculturists generally of the services of all who have been endeavouring to apply science to the advancement of agriculture (cheers). It is, therefore, gentlemen, not in my own name alone that I return thanks for the beautiful testimonial which you have presented to me, I return thanks in the name of all who have been fellow-workers with myself, of whom there are many both in England and abroad. I return thanks, I say, in their name as well as my own, for this testimony from the art of agriculture to the practice of science (cheers). I would only say in conclusion that I feel deeply indebted to all the subscribers for the very handsome testimonial which has just been presented to me, which I trust will cause me to redouble my efforts for the advancement of agriculture (much cheering).

The CHAIRMAN said they would now proceed to the discussion of the evening. He was quite sure they would all be as much edified by Mr. Nesbit's remarks on that occasion as they had been by his previous efforts; and, without taking up any more time, he would now call upon that gentleman to open the discussion.

Mr. NESBIT then rose and said: Mr. Chairman and Gentlemen,—I really feel that I am placed in a position of some difficulty this evening. There are so many practical drainers around me, who have been working in the soil with deep drains and shallow drains, and every variety of drains, that I cannot help feeling that one who does not even profess to be a practical drainer, might by some be fairly considered to be presumptuous in appearing before such an assembly. We have had many excellent lectures on this subject, including the philosophical lectures of Mr. Parkes and the able disquisitions of Mr. Bailey Denton. We have our deep drainers and we have our shallow drainers, Mr. Bailey Denton representing the one on this occasion, and Mr. Bullock Webster the other; and I must declare at once that I do not belong to either class. I come before you to-night, not to advocate deep draining or shallow draining, but to endeavour to deduce from the nature of the soil itself the laws which ought to govern the art of draining in different localities. Beyond that I do not presume to go. I shall lay down certain principles, and leave those who have the practical management of drainage operations, so far as they may find these principles consistent with fact, to modify their practice by them. Now, in the first place, setting aside the different modes of carrying on drainage, let us look for a moment at the difference between a drained and an undrained soil. Let me remark, at the outset, that I have no wish to ignore what has been done by others in relation to this subject; but I feel that, in a lecture like that which I have undertaken to give, I ought to begin, as it were, with first principles, and not to take everything for granted. I am perfectly well aware that

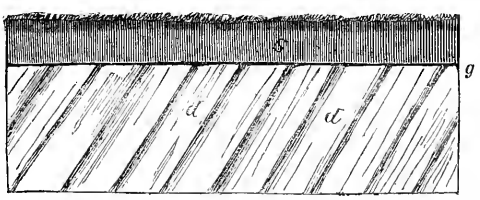
many gentlemen now present are at least as well acquainted as myself with what I am now about to state; but nevertheless I must, for the purpose of clearing the ground, commence by laying down elementary principles. Now what is the difference, chemically, between a drained and an undrained soil? An undrained soil is, I apprehend, not simply a soil in which water is present, but a soil in which water is present to an abnormal extent—to an extent that will injure the vegetation. The question then arises, how does an excess of water injure the condition of the soil? If you have a large quantity of water very near the surface of the soil, that water by its evaporation produces cold; the land is, in consequence of being undrained, very much colder than it otherwise would be; in other words, the average temperature of the soil, throughout the year, is very much lower than it would be, if the water did not approach so near the surface. That is one case. We will take another—that in which the water-level does not come to the top of the land, but so near to it, that the mere capillary attraction of the soil will bring the water to the surface. Here you have a second case of injury from excess of water, though not so bad a one as the first. Now, in order to illustrate what I mean by "capillary attraction," I will just set at work a little instrument which I have on the table, the action of which will proceed while I am speaking. I have here, in a glass tube, a quantity of dry sand. The bottom of the tube is covered with a small piece of linen, to retain the sand in the tube. I have also a little cup containing water. I will now insert the bottom of the glass tube in the vessel of water. You will observe that the water rises through the pores of the sand much higher than the level of the water in the cup. The power which causes the water to rise is called "capillary attraction"—that is, the attraction of minute tubes. [The water rose in the tube many inches above the level of the water in the cup.] Now, what is styled "capillary attraction" is simply the power which all soil has, under certain circumstances, of taking up water by attraction beyond the ordinary level, into the pores of the soil itself. Capillary attraction has a very important bearing on the question of drainage, as respects both the depth and distance of collateral drains. I wish to impress upon you this point—that, where the soil is exceedingly fine, where the pores of the soil are very minute, capillary attraction will raise the water much higher than it will where the soil is of a gravelly and coarse character. In the more porous soils, water will not rise so high as in soils of an opposite description. It is a well-known fact—a fact which might be exhibited by means of glass tubes drawn out to different degrees of fineness—that the finer the tubes or pores, the higher water will ascend in them. It must, therefore, be borne in mind that the capillary attraction of the soil will necessarily exert a considerable influence on its condition. This ought to affect the judgment of every man who puts a drain into the land, because, in proportion as the capillary attraction of different soils varies in force and amount, so the modes of draining those soils properly and effectually must vary likewise. Another point of considerable importance is this—that, in drained land, not only have you got rid of the evaporation of the water from the surface of the soil, but the soil at the surface, being warmed by the rays of the sun and by the diffused heat of day, warms the water that falls on the soil; and that water, in passing downwards, leaves its heat in the soil. You see, therefore, that, if a soil be capable of deep drainage, the deeper the drain, within certain limits, the greater will be the amount of soil heated by the water that comes from the surface. There is a very important point relating to the distance of drains, upon which I shall say a few words hereafter. Another effect presents itself here—namely, that, after the water has entered the soil, the air must follow it. So that you have two courses of action. You have the water heated, particularly in summer weather, passing downwards, and warming the soil; and you have the warm air following afterwards, and also warming the soil. Besides that, the drainage has a distinct action in disintegrating the mineral matters of the soil for the purposes of the plant, and in oxidizing the vegetable matters, and furnishing means by which the process of vegetation may take place more rapidly than it otherwise would do. Thus good drainage replaces rank weeds and grasses by grasses of finer quality and more nutritious properties. [Mr. Nesbit here illustrated the fact of the retention of heat in soils by pouring heated water on some soil in a glass vessel. The hot water, after passing through eighteen inches of soil, issued therefrom quite cold, the heat of the water being retained in the soil.] It is quite clear that, in such a case, the heat left in the soil must have warmed the roots of the plants growing in that soil. I am obliged of course to use, in performing this experiment, a rather coarse species of soil, because I must make, as it were, a week's rain pass through in a very short space of time. In the soils themselves to which I have been referring, the action is, of course, not so rapid; but the principle is the same.

Mr. Mechi: The fall of rain in the first instance expels the air?

Mr. Nesbit: When water falls on dry and porous soils, it first, as it descends, drives out the air, and is then itself followed by air from above. The question of deep and shallow drainage is one which you will have to determine, in each case, upon its own merits (Hear, hear). The experiments which I have to exhibit will, however, evince clearly that there is no one decided depth, and no one decided width, at which it can be laid down as a rule that all draining should be carried on, but that draining must vary according to the circumstances and condition of the soil (Hear, hear). What I wished to do was to illustrate the fact that when water is heated at the surface, and then passes downwards to a drain below, it issues, in spring and summer, very much cooler.

A Member: Is that regular soil?

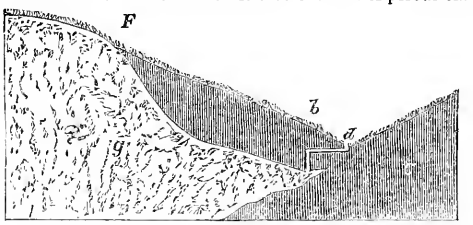
Mr. Nesbit: It is a gravelly soil. You see, then, very clearly that, so far as chemical principles are concerned, we have here the passage of the water through the soil and the alternative passage of air; and thus we have the irrigation and the aëration of the soil accomplished in the most beneficial manner by means of drainage. If you now look to this illustration of capillary attraction, you will see that the water has risen some four or five inches, in apparent opposition to the principle of gravitation. Well, now, before I proceed to speak of simple, regular drainage at so many feet distant, such drainage as uniformly-pervious soils must require, let me refer to a few facts in connection with the drainage of springs, and of certain particular soils in various localities. The case of the drainage of springs is one that ought, perhaps, to be considered separately from that of the ordinary gridiron draining, as it has been termed; but it is very often found that, by one or two drains, one can set free a very large tract of land from the water that comes in from a higher level. I have here [referring to some diagrams suspended against the wall] illustrations of a few cases to which I wish to allude. The first case to which I shall allude is the most ordinary one. It is one which very frequently occurs in the West of England.



[Diagram No. 1.]

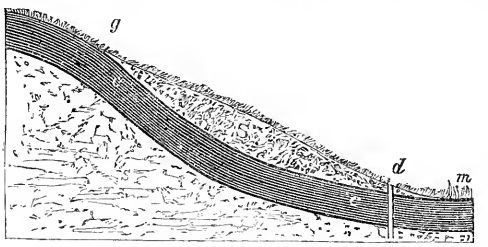
Here you have the rocks themselves upon which the vegetable soil rests stratified very nearly vertically (as represented in Diagram No. 1); you have a pan *g, g*, almost impervious to water; and upon that pan you have vegetable earth. Now, instead of this soil requiring to be drained in the ordinary way, the subsoil plough is, in fact, all that is wanted. If the line *g g* be cut through by the subsoil plough or otherwise, at proper intervals, the land will be drained by the percolation of the water through the fissures of the rock. It must be recollected that the plough must pass transversely to the stratification. You just plough the subsoil, so as to break the pan; and if my friend Mr. Robert Smith were here, he would tell you that a very considerable portion of Exmoor has been drained by him in this manner. Where the upper surface of the nearly vertically-stratified rock is too deep to be touched by the subsoil plough, the simple breaking-up of its outcrop at suitable

depths and distances will often effect the same object. That is the first case. Another case is that of a hill of porous cha-



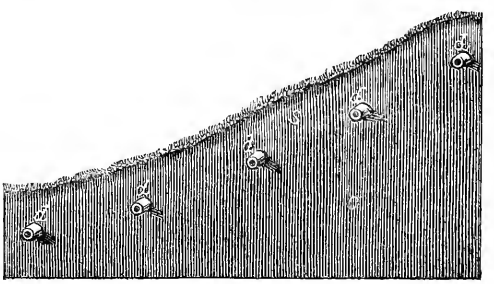
[Diagram No. 2].

racter, with a valley consisting of clay, and the water continually running over the edge of the clay where it abuts upon the gravel or other porous soil at the point *F*, as represented in diagram No. 2. Now the plan of Elkington was simply to make an outlet in the bottom of the valley, to cut towards the hill, and at the proper point to bore down until he tapped the porous soil *g*. The water immediately issued forth, the level was reduced below the junction *F*, and the whole land between *F* and *d* was consequently laid dry. His great point was to hit the porous gravel at the point *b*, as he might have bored to any depth at *d* without any effect. By operations of this kind he often succeeded in laying dry very considerable tracts of land. Take another case diagram No. 3 represents a porous soil resting on clay.



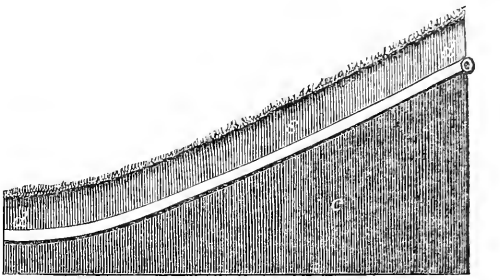
[Diagram No. 3.]

Here is a stratum of gravel or porous soil, resting on clay. All the water which falls between the points *g* and *m* issues at *m*, and makes the subjacent land beyond *m* wet and swampy. A cutting at the point *d*, simply into the clay, where there is an outfall, will cut off all the water between *g* and *d*. If there be a porous stratum below the clay, even without an outfall, the land can be drained by cutting through the clay to the porous subsoil, into which the water will empty itself. I believe I could point to gentlemen in this room, who have adopted this plan of proceeding in many instances. Many similar cases of juxtaposition of porous and retentive soils, where similar means may be made use of, will occur to every gentleman present. We now come to general, ordinary drainage. And the first question which here presents itself is, whether the drains ought to be on the greatest slant, or horizontal, or at some angle between. I have here two diagrams which will serve to illustrate this point. Diagram No. 4



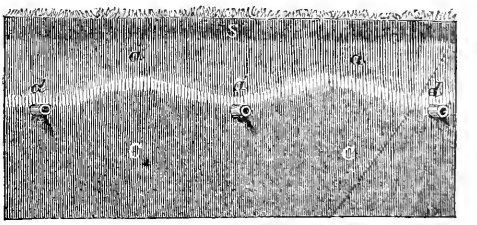
[Diagram No. 4.]

represents a section of a hill, with drains running horizontally—that is to say, at right-angles to the fall of the hill. Now it is quite clear that each of these drains only acts in a horizontal direction. Each drain is acting separately on a small piece of land: it cannot act upon the general mass of the land below it. On the other hand, where there is a drain running down the hill—that is, in the line of quick-



[Diagram No. 5.]

est descent—that drain will act upon the whole of the hill, from the top to the bottom. So that it is perfectly clear that you apply your labour and time and money to the greatest advantage when you drain on the line of quickest descent. There may, however, be some exceptional cases where a deviation at some angle from the line of quickest descent may, owing to local peculiarities, be necessary. These cases cannot affect the general rule. These are principles which I am attempting to lay down distinctly for consideration. Of course they are open to discussion: and I hope myself to obtain a great deal of information, though I think that what I have said is for the most part sufficiently simple. Another question to be considered is, What should be the distance of the drains apart? On this point, I wish to illustrate that the different capillary attraction of various soils, and their rates of resistance to the passage of a certain amount of water in a given time, must be distinctly taken into account, not only in regulating the depth of drains, but also their distance. This applies more particularly to porous soils, which have a water-level more or less near the surface. It does not equally apply to those real clay or other retentive soils having no real water-level, which, in fact, give no trace of water, even when penetrated to the depth of fifty or one hundred



[Diagram No. 6.]

feet. In diagram No. 6, *S* represents the surface-soil, *a a* the subsoil, *d d* the drains, and *C C* the water-bearing soil beneath the drains. According to the varying degrees of fineness of the particles of the soil, and consequently the resistance to the passage of the water, so will the water rise higher in the soil between the drains; the water-level in drained lands not being a horizontal plane, but an undulating or curved surface, the height of which, above and between the drains, must vary according to the mechanical fineness and condition of the soil. The light line passing the drains represents the water-level. From these facts it would appear that the greater the distance of drains apart, the higher will be the water-level between them; and that this ought to be taken into consideration by practical men in their practice of drainage, in respect to both depth and distance. The amount of the resistance of different soils to the passage of water in a given time has, in my opinion, not yet been taken into sufficient account. In continuation; I mentioned before that if the water came near

the surface, and evaporated, it must produce cold. Well now, gentlemen, suppose you had to drain a piece of land, and this [pointing to the light line in the diagram] was the water-level, where actual water existed as water, the land would take up by capillary attraction many inches of water that would not run out of it afterwards. It is quite clear that that would bring it within a certain distance from the surface; but it is equally clear that, if this water comes too near the surface, and evaporates, it will produce cold. The consideration of the proper depth of the drains, then, appears to depend partly on the degree of power of the soil to raise the water beyond the water-level; and, in order that a soil may be a workable soil, the consideration of the proper depth of the drains must be determined with reference to the force which the soil exerts in raising the water from below, as well as to the resistance, *in time*, which it offers to the passage of the water through it. Now there is one point of very considerable interest, the importance of which has I think been too much overlooked, viz., as to the depth to which water will penetrate into the earth or soil. Are there no limits either as to distance or time? What answer should we give to the question—"How far will water penetrate into soils?" Upon a careful consideration of this question, I think that the following answer will, in terms sufficiently simple, express a general law which governs all cases: "*Until the resistance to its downward passage equals the pressure from above.*" If the soil be porous, the water from above will pass down until it reaches the water-level; and when it reaches the water-level, it meets with opposition and begins to rise. But where is the point in a clay-soil—a homogeneous clay-soil—at which the water will issue? We cannot talk of a water-level in clays where no water can be found, even at a depth of fifty or sixty feet. But some soils like these are those precisely which most require draining from surface-water. There is a depth in these soils beyond which surface-water will not penetrate; and this depth will vary with the varying fineness and tenacity of the soil. These considerations ought, therefore, to exert their proper influence on the art of the practical drainer. Let me here observe that a vast variety of the soils which are called by farmers clay-soils, are not clay-soils. If you show me a soil which requires an admixture of forty or fifty per cent. of sand before it will make a brick, I will admit that to be a clay-soil; but when a soil will make a brick without any admixture of sand, I cannot admit it to be a real clay-soil. The question of drainage therefore, we see, in depth and distance, depends on the fineness of the particles and pores of the soil; the amount of capillary attraction, and last, though not least, the amount of resistance a soil offers to the passage of *a given quantity of water in a given time*. Let me here remark that one great element appears to me to have been very much neglected in all discussions on drainage. I say this without intending any disparagement of the admirable lectures which we have had on this question. I mean that *this element of time* has not been sufficiently taken into consideration. A friend of mine, who is present, has tried some experiments for me, illustrating this subject. He has got a clay on the top of one of his hilly farms, in which he has sunk fifty feet without getting any water. At my request, some trial-holes five or six feet deep were sunk in this clay, the upper rim of the holes being a little raised, to prevent water entering directly at the surface. The object in view was to find where and when the surface-water would enter the pits, under rain-falls of different quantities. Under these conditions it was found that, when there fell a large amounts of rain in a short time, the water began to ooze into the pits about one foot from the surface, the resistance to the further passage of the water downwards being at that point sufficient to prevent its further descent with sufficient rapidity. On the other hand, when the rain-fall extended over a much greater length of time, and was consequently more gradual, the water was found to penetrate to the depth of two feet, which was the lowest depth observed. I think a fair deduction from these experiments must be allowed by all to be, that "the *degree* of resistance of a soil to the passage of a given *quantity* of water in a given time ought to have its proper influence in regulating both the depth and the distance of drains." Another conclusion which I think we must inevitably draw from these facts is, that the assertion that deep drains always run the first is not always correct. If this clay-land had been drained at one foot depth and at two feet depth, it is apparent that, under the condition of a rapid and heavy fall of rain, the drain at one foot deep would have run the first, and that, besides, a considerable quantity of water would have also escaped by simply running over the surface of the land into the nearest ditches. The effect of varying amount of rain-fall in a given time is easily illustrated. I have here a glass vessel filled with soil, having three apertures—one near the bottom, one in the middle, and one some distance from the top. If I pour in water at such a rate that the pores of the soil will permit it to percolate through them as fast as I pour in, the water will descend to the bottom, will then rise, and will issue from the lowest opening first. If I pour in more water than the lowest aperture or drain can discharge, the water will rise in the soil, and at length issues at the middle drain. If I continue still to pour in an increasing quantity, the water will rise to the top drain; and all three will discharge their respective quantities of water. If I now discontinue pouring in water, you will observe that the upper drain first ceases, then the middle one, and subsequently the last [Experiment performed]. This is the ordinary state and condition of porous soils. It is, however, as before stated, different in those soils which offer greater resistance to the passage of water through their pores. Even with this same soil, in which you have seen the lower drain run first, the fact would be reversed if I were to pour in water faster than the soil could permit it to percolate. I will now pour in the water with some rapidity, when you will see the *upper drain run first* [Experiment performed] (cheers). This last case is strictly analogous to the results obtained by my friend Mr. Hatfield, where he observed that the heaviest rain issued at the shallowest depth. It is, therefore, a question of the rapidity with which water will percolate through the soil; and I state it to be my deliberate opinion that, unless you pay sufficient attention to *the time* which water will occupy in going through the soil, you cannot drain upon scientific principles. There is another point, gentlemen, which I wish to introduce. It is one that I approach with great diffidence; but I must say that it is just possible to have a mania for drainage, and it has often occurred to me that in some cases it would be well if instead of further draining there were irrigation (Hear, hear). I would suggest that there is such a thing as *natural* overdrainage; that I have seen such a thing, in such soils as the sands resting on chalk, in the district between Bury St. Edmund's and Brandon in Suffolk. Has there been no such thing as overdraining *artificially?* I would submit for the consideration of practical farmers the inquiry, whether there be not many cases in which the land of this country is drained too much. It is a well-known fact—I cannot doubt that it is well-known to most present—that if you have a piece of fallow land exposed to the action of the atmosphere, and have another piece of land under crop (say vetches or winter tares), when you come to plough them up you will find the latter quite dry and hard, compared with the former (Hear, hear). This difference is accounted for by the fact that every leaf of the vetch has its little root or tube with ramifications running downward into the soil, and that all the moisture of the soil is brought up by the roots to the surface, where it evaporates by the leaves of the plant. This may perhaps account for the difficulty often experienced in getting a good crop of turnips after tares. But does not the evaporation from the leaf and the absorption likewise of water by the roots of the plants, as in the case of grass and meadow lands, seem to point to the necessity of more water than in ordinary arable land? And in the case of the constant evaporation from grass-land by the leaves and roots, may not the water level, without danger of injury from stagnant water, be allowed to approach a little nearer the surface than in arable-land? It is the opinion of many practical men, and I submit it to you with great diffidence, that some grass-lands may have been *over-drained*—that the water has been taken away too deeply from them. It is one thing to remove an excess of water; it is another thing to take away what is necessary for crops; and therefore any invariable depth—any depth, that is, like the laws of the Medes and Persians, to be observed in all cases, and in all varieties of soil—is, in my judgment, founded in error (Hear, hear). Well, gentlemen, it was not my intention to deliver a long lecture this evening, but simply to present the points which I have laid before you. I have spoken of the rate at which water will descend through the soil. That is a question which must be determined by

actual trial and experiment before you can arrive at any conclusion, either as to depth or as to distance. Time is a most important element, and ought not to be forgotten. Capillary attraction is also most important. I leave it for your decision whether in grass lands the water may not be allowed to approach nearer the surface than in arable land. I shall be happy to learn from many gentlemen whom I see before me; for I know that they have had a great deal to do practically with the art of draining. I have endeavoured to lay down certain principles which appear to me to be correct, and without detaining the meeting longer, I now leave others to enlarge upon the practice of draining (Cheers).

Mr. MECHI: What is your opinion with respect to distance in the case of stiff clays?

Mr. NESBIT: I do not believe depth can ever fully compensate for undue distance.

Mr. MECHI (of Tiptree) said: It was now ten years since he first began to drain, and he had cut altogether, probably, a hundred miles of drains, under the advice of Mr. Viall, a well-known agriculturist in Suffolk. As they were no doubt aware, he had at first made his drains 12 feet apart and 2 feet 8 inches deep, and put stone at the bottom (for which his friend Mr. Pain had laughed at him) and the pipes at the top. That was on a very tenacious plastic yellow clay, almost like birdlime, with a great deal of iron, but no lime. Subsequently he had drained other lands to a considerable extent 4 and 5 feet deep, at intervals varying from 23 to 50 feet, still on the same kind of clay. After ten years' practical experience on that land, his labourers were now able to form an opinion upon the comparative value of the drainage; and they told him, and he himself believed it from his own observation, that they could always plough easier and work with one or two harrowings less on land drained 12 feet apart and 2 feet 8 inches deep, than on land drained four or five feet deep at wider distances. (Hear, hear.) He had taken the trouble to cut across these drains occasionally, for the purpose of noticing the action of the water, and he found that the stones, which were put in in very small quantities, were perfectly clean, and the pipes were never called upon to take in any water (a laugh). But, owing to ths ventilation of that soil, or to some circumstance which he could not perfectly explain, there was an equality in the crops, and an evenness in the yield, both on the furrows and the other parts of the land, that afforded unmistakeable evidence of thorough drainage. Having read Mr. Parkes's paper, and feeling the jeers of some of his Bedfordshire friends, he was, at one time, inclined to think that he had done wrong; but he was now convinced that the distance between the drains was a most important element on these soils. He wished to guard himself to that extent, because he had drained on other soils of a more friable character six feet deep, and there the drainage had been very different from that on the yellow homogeneous soil, free from lime, but containing a large quantity of iron, which he had mentioned. True, the drainage cost £10 an acre; but even if it were more, it would have been very profitable to him. Indeed, it had been profitable, as it was; and to this day he believed it was the best drainage he had ever executed—an opinion which was not confined to himself, but was shared in by all who had seen it. One subject which Mr. Nesbit, in his able lecture, had not touched upon, was the necessity for having open furrows on these kinds of soils. His (Mr. Mechi's) experience, and that of many others, was that during the winter open furrows were of advantage, and acted occasionally as drains, although the other drains might be running abundantly. In order to test that point, he had left an acre in each field on the flat; the rest being the ordinary furrow, at seven feet apart. Now, he was free to confess that, contrary to his own expectations, when the land was ploughed a year or two afterwards, he found that, where it had been laid on the flat, it was of a more homogeneous and less friable character than where the furrows existed (Hear, hear). He was there to speak the truth, and not to advance any mere crotchet of his own; and he did believe that the ventilation of homogeneous soils was a very important matter (Hear). He knew practically, as a horticulturist, that, if he wanted to grow roots or plants on such soils, he must take the ventilation or circulation of the air below into account; and he apprehended that the pipes which he placed on the top of the stones had produced very beneficial results. That fact, then, he commended to the consideration of his friend Mr. Bennett (a laugh). When he drained deeper on other soils, he did so for this reason—that he was a tenant on part of the land, and was not sure how long he might continue to be so: he therefore drained four or five feet down in the strong clays, at intervals of thirty, forty, and fifty feet apart. That drainage had turned out to be very profitable, and the crops were very good, though he readily admitted that the land was not in so satisfactory a condition as the land which he had treated on the other method of twelve feet apart, and two feet eight inches deep. With regard to spring drainage, he had certainly some drains twelve feet deep; and he thought there could be no doubt that, on friable soils, they must cut off the spring at the lowest point, in order to prevent the water from rising, and saturating the soil. He would merely observe, in conclusion, that not to drain the strong, tenacious clays, would be a most ruinous thing to British agriculture.

Mr. R. BAKER (of Writtle) congratulated the meeting upon having had the subject treated in so purely scientific a manner by Mr. Nesbit. Hitherto, when it had occupied their attention in that room, professional drainers had come there, and not unnaturally advocated the particular systems which they had found best adapted to their own localities; but it had been the object of Mr. Nesbit to instruct them as far as he could scientifically, with regard to the principles on which drainage ought to be applied to various descriptions of soil. Upon all occasions there seemed to have been a great diversity of opinion on this subject. Some persons lived in districts where there was a retentive soil on the surface, and a porous soil below; whilst others resided in districts where the porous soil was above and the retentive soil below. Of course, therefore, the process of drainage in these localities would be extremely dissimilar. Nature had so arranged it that in geological strata we constantly found a porous surface with a retentive subsoil, or a retentive surface with a porous subsoil; but neither continued for any great depth without reaching the other. Thus the order of Nature was preserved, and sufficient moisture was retained for the growth of vegetables for the use of man. Now, the process of drainage must, as Mr. Nesbit said, vary according to circumstances. Wherever there was a porous subsoil continued from a valley to a hill the water would always be endeavouring to escape upwards; consequently, in all such cases, the system of deep drainage must be pursued, in order to intercept the water at the lowest point before it reached the surface. That was one description of drainage. Another description was that to which Mr. Mechi had referred. He (Mr. Baker) had had some experience in drainage; but chiefly upon land where the retentive subsoil was near the surface, and he found that a certain depth of drainage on a homogeneous clay, at suitable distances—say 5 or 6 yards—was the most beneficial. He made his rains 6 yards apart, and 30 inches deep; and he was engaged on one occasion in draining a field according to this system, when the *Times* Commissioners paid him a visit—their object being apparently rather to condemn than approve of what they saw. When these gentleman entered the field he was draining at a depth of 30 inches. One of them asking him what he was doing. He replied, "Draining." "Oh, dear, no!" was the rejoinder, "you are not draining, nor making an attempt to drain." He (Mr. Baker) ventured to ask, "Why?" "Because you are not going deep enough. You should put in your drains 4 or 5 feet deep, instead of 2½ feet deep." In answer to that, all he (Mr. Baker) said was, that if a hole were sunk in that soil to the depth of 4 or 5 feet, and filled with water, there was not a hydraulic machine in London that would force it into the drain. He then made a drain 3 feet deep, and cut a parallel drain exactly 1 yard from it, but leaving the parallel without any opening except what it possessed from percolation. It was filled on Friday night, and on Monday it had only sunk 1 foot, and the water was percolating from the ditch in a manner which convinced him that it had never entered the pores of the subsoil. He then proceeded to drain the remaining portion of this field. The largest part was drained 3 feet deep, with pipes, and filled up in the ordinary way. Another portion was drained 4 feet deep; a third portion in that *execrable* mode which had been so

much condemned in Essex, of using wood and straw; and a fourth with a common mole-plough. There was the field to this day, and he defied any person to tell where one system was adopted, and where another.

Mr. MECHI: Did the crops show any difference?

Mr. BAKER never observed any difference in them. With regard to the running of the lower drains first, of which Mr. Nesbit had favoured them with some experiments, he would observe that those experiments, though undoubtedly very interesting, proved nothing. Mr. Nesbit had adopted gravel for his purpose, and every one knew that water would pass through gravel to any depth. In fact, if they all had soils of that description, they would never require any artificial drainage, for the land would drain itself. The water would go down until it met with resistance. By capillary attraction the water would rise to the soil above, and the result would be that the same process would take place as Mr. Nesbit had exhibited with his tube. He had no wish to contradict Mr. Nesbit, because he was sure every one present felt indebted to him for the able and scientific remarks he had addressed to them that evening. (Hear, hear.) But he had constantly found that theory did not constitute practice, nor did practice always corroborate theory. Unless it could be shown that the particular circumstances of the soil, the quality of the subsoil, the position of the drains, their depth and distance apart, always corresponded, they could not arrive at any correct conclusion. In fact, the circumstances attendant on draining operations were in no case ever alike. (Hear, hear.) Mr. Mechi had certainly tried all the different systems. He first put stones below and the pipes at the top of the drain, which many persons thought absurd. Some one had told him that water would rise through the stones, be beautifully filtrated, and pass through the pipes (laughter)! He then changed his plan, and drained in a manner that he had not mentioned to-night. The pipes were placed at the bottom of the drains, and some of his neighbours on seeing them expressed their doubts respecting the purpose for which they had been put there, and imagined that as some of them pointed upwards they were intended to catch the rain (laughter). But he (Mr. Baker) had no desire to be too hard upon his friend Mr. Mechi, who had certainly been a very effective engineer, and contributed much towards making the subject of drainage familiar to the British farmer. His efforts had been attended with a great deal of good, and although he might not have cut very keenly himself, he had proved a capital whetstone for other men's minds. (Hear, hear, and laughter.) Mr. Nesbit had told them, and he (Mr. Baker) wished them to adopt it as a principle, that no depth of drain would compensate for distance.

Mr. MECHI: On certain soils.

Mr. BAKER: If they were draining a retentive soil, with a porous soil below, they could not go too deep, because the water had not the power to escape upwards. If they were draining a thoroughly homogeneous soil, they might depend upon it they would gain nothing by going deep; and provided they went deep enough to protect the drain from injury, that was sufficient. As he had before remarked, different systems must be applied to different localities; the same method would not answer under all circumstances (Hear, hear). He himself had been draining considerably during the present year, and had used Fowler's plough for putting in the pipes. Upon that system he had drained seventeen acres of land; and he believed that there was no other mode—not even the spade—by which draining could be so effectually accomplished, for it not only drained, but opened the soil. The drains worked remarkably well, and the pipes answered better than if they were put in by hand. In saying this, he merely gave that method the meed of praise which was its due; and he would only observe, in conclusion, that it would not do in these matters to rely too much upon theory. A theory might be very good under one set of circumstances, but very bad under another.

Mr. MECHI denied that any part of his land had been re-drained, or that he was expecting the water to rise up to the pipes (laughter). He had simply used the pipes with a view to ventilating the soil, and as the cheapest method of preventing the yellow birdlime-like soil from sinking between the stones. He wished to add that he had drained very deep on stiff clay soils. When he irrigated the land in summer with liquid manure, he made the drains 5 feet deep, and on these tenacious soils the drains ran from the effects of irrigation at that depth.

A MEMBER: Have you ever drained at 5 feet?

Mr. MECHI had drained 40 acres 5 feet deep. In one field the drains were 23 feet apart, in another 40, and another 50. They all paid well, but the land did not look so kindly, nor pay so well, as the other part.

Mr. BAILEY DENTON (of Stevenage) was s was sorry to find that his friend Mr. Mechi was still wavering (a Voice: "He is decided"). He could account for the circumstance, however, when he recollected that he was comparing drains at 50 feet intervals 5 feet deep, with drains at 12 feet intervals and 2· feet 8 inches deep. Now, he should like Mr. Mechi to inform him whether draining four or five feet deep, at intervals of twelve or eighteen feet, would not have ameliorated the soil to the full depth of the drains and to an equal extent with the less depth and the nearer intervals. There might be excess in all things, and he thought that in this case Mr. Mechi had run from one extreme to another. He was sure he should not be charged with any discourtesy if he said that there were several facts, or assumed facts, contained in Mr. Nesbit's lecture, to which he could not give his assent. He observed that that gentleman had adopted the old trite illusion that there was no water level in clays; and had also alluded to the case of a well of which he had heard his friend Mr. Bullock Webster speak before to-day. Mr. Nesbit said that water would not accumulate in a well. Now the simple answer to this was, that a well was a hole pierced in the soil, and could only have any effect upon the space immediately around it, which was not sufficient to fill it. What was the object of draining? The perfect aëration of the soil. When the soil had been uniformly aërated from one drain to another, the water as regularly descended—for this reason, that it was ust 817 times heavier than the air which was displaced by it. The level of the drains then became the level of standing water. That was one of the principal points in drainage, and it disposed at once of the illusion that a well was any criterion of a water level. They knew from observation that deep drains ran before shallow in all cases (A voice, "No, no.") Excuse him, he would repeat that deep drains, under equal circumstances, always ran before shallow.

A MEMBER.—Not on a clay soil.

Mr. B. DENTON.—It was not mere assertion that would decide the point; and, if he had expressed himself decidedly upon that subject, it was not from any dogmatic opinion of his own, but because he was sure of the accuracy of what he had said, as the result of a most minute and careful examination of the facts. Mr. Thompson, of Moat Hall, has most beautifully and conclusively explained the cause of deep drains running before shallow ones. Contradiction would not dispose of the question. Truth must, in the end, prevail; and what he had stated was the truth. Another point to which he would refer was the idea which had taken possession of some minds, with reference to Elkington's system of drainage. That was a system which certainly had an existence in the practise of Elkington, and a prize of £1,000 had been given to Elkington for its discovery; but it had not existed since (an expression of dissent). He repeated, that both as to principle and system it had not practically existed since Elkington's time. That might be regarded as a bold assertion, but he waited to be informed that the principle had been confirmed by subsequent practice. With regard to the swallow-hole system, nothing could be more lazy than that, except under peculiar circumstances. There were no doubt cases of pans near the earth's surface for which there was no outlet. Of course in such cases they might adopt this expedient; but rather than lay that down as a "system of drainage," he would blot it out from the practice of agriculture. He could mention if necessary several instances in Yorkshire, Hertfordshire, and other parts of England, where the swallow-hole method had been adopted; and if it were possible to ride in a balloon over the land so treated, they might in every case fix upon the particular places where it had been applied. They were black spots upon the earth's surface, regular scabs, owing to the non-existence of anything like a proper outlet, and the consequent destruction of the surface crop. Mr. Nesbit had adopted a corrugated line as the line of water level on clay soils. He (Mr.

Denton) thought that gentleman had disputed the existence of a water level altogether. That line, if it existed at all, was simply attributable to the superior power of capillary attraction; there was no line of positive wetness on drained land above the mean level of the drains. He believed that if test holes were made in drained land, and left open for a certain time, an atmospheric action took place on the sides of the holes, and an expansion of the soil, which prevented the water from passing through. They must not, therefore, take test holes as a criterion of drainage in all cases; although on any other lands than clay no doubt they were so.

Mr. MECHI: Mr. Parkes made his test-holes with pipes of clay around them.

Mr. THOMAS (Lidlington) said that Mr. Nesbit had contrived to divest the subject of all empiricism, and shown, as far as it could be shown, that no particular system of drainage was suitable for all kinds of soils. It was much to be regretted that rival drainers, whether professional or amateur, could scarcely ever meet without declaring their own plans to be absolutely perfect, and all others to be essentially wrong (Hear, hear). Most of them had, no doubt, read that interesting work, "The Adventures of Gil Blas," in which Dr. Sangrado laid it down that bleeding and copious draughts of hot water were a certain specific and cure for every sort of disease; but Dr. Sangrado himself was not a greater impostor than the man who contended that one particular system of drainage, at one uniform depth, was applicable to all soils (Hear, hear, and laughter). The present discussion seemed to tend to two practical conclusions, both of great importance. One was, that no depth could compensate in the case of homogeneous clays for too great a distance between the drains (Hear, hear). The other, that in the case of friable and springy soils they could hardly go too deep (Hear, hear). In the case of springy soils at Lidlington, he (Mr. Thomas) had gone down to a depth of twelve and fourteen feet, but he did not maintain that depth was necessary in all cases. There was one point upon which, as a practical man, he differed from the lecturer. It was, that at all inclinations of the soil, the drains should be taken up the steepest acclivity. Up to a certain angle that was no doubt very good, but it was not of universal application. He himself occupied a good deal of land on wet and precipitate hills, and he was satisfied, by experiment, that the system would not answer there. With regard to the overdrainage of grass land, he had seen it done so often, on so many hundreds of acres, that he could not help expressing his entire concurrence in what had been said upon that subject by Mr. Nesbit. What they wanted was, that the land should be sufficiently dry for the cattle, and at the same time sufficiently moist for the production of grasses, and that object was not always kept clearly in view. On the whole, he thought they might safely arrive at the conclusion that it was impossible to lay down any known rule in drainage as of general application to all soils (Hear, hear).

Mr. BULLOCK WEBSTER said it was only a few years ago that he stated, as his opinion, that certain grass lands might be over-drained; and when he did so, the *Quarterly Review* declared that such a remark could only have emanated from a hermit, brooding over his own ignorance, in a garret in London (laughter)—that it was only such a man who could entertain the idea that grass lands could be over-drained; now the discussion to-night showed this idea was not entertained by himself only. There can be no doubt as to the importance of deep drainage for springs; and in porous subsoils, deep drains at wide intervals are more economical and beneficial; but that in the retentive clay subsoils, not surcharged with underwater, he had always taken a decided part in opposition to draining below thirty-six to forty inches; as these soils require drainage for surface water, and the object was to get rid of that quickly. But he had hardly expected his friend Mr. Mechi to admit in so straightforward a manner that his shallow drains had answered best. He believed that the practice of going deep in strong clay subsoils was only a waste of money; and his friend Mr. Denton, who had advocated that system for many years, now allowed that they could not put their drains further apart in consequence of the increased depth.

Mr. DENTON: I never said that. I have always been of opinion that depth does not compensate for distance.

Mr. WEBSTER: Then to make the drains an extra foot deep could not effect the slightest good. It was only to incur extra expense, without any corresponding advantage. After the many years' experience they had had, he was sure there must be at least five hundred practical farmers in England who were able to state whether or not a depth of four or of three feet was best in the case of strong clay soils. (A voice: More; there are five thousand). He held, then, that they ought to come to a practical conclusion as to what was right in the case of these soils. Every day's observation and experience increased his conviction that his own views were correct, and that evening's discussion had afforded a most gratifying confirmation of their accuracy.

Mr. MECHI asked how far apart Mr. Webster placed his drains?

Mr. WEBSTER: The closer the better. I should like them to be eighteen feet.

Mr. HATFIELD, (of Euston, Stamford,) said that having had some experience of draining upon retentive clay soils, he should like to make one or two observations upon the subject of that evening's discussion. Before commencing the drains he dug a few trial holes of about five feet in depth; he covered them carefully, and watched when the rains fell for the purpose of ascertaining at what depth the waters entered, as a guide how he ought to drain his land. Now he found that whenever there was a continuous heavy fall of rain it would enter the pits at one foot, but in a moderate fall of rain it would enter the pits at a depth of two feet. He concluded, therefore, that it was necessary to go sufficiently deep below the two feet, in order to arrive at a method that would be applicable to all the circumstances of the soil. Adopting that system as a standard for his drains, he went down thirty inches, and afterwards increased the depth to thirty-six inches; and for ten years he had found that thirty-six inches would drain the land most effectually.

Mr. B. WEBSTER: In what county do you farm?

Mr. HATFIELD: Northampton; and the drains answered admirably. But there was another point which entered into the question of drainage, and that was the cost. He had therefore made one description of drain in this manner:—He cut a drain three feet deep, and nine inches in width at the top and gradually tapering away to an inch-and-a-half at the bottom. This he performed with tools made for the purpose. The first spit was thrown on one side, the second on the opposite side, and the third on the same side as the first. The second was then returned to fit the drain in the same manner as the key-stone of an arch. In order to avoid the expense of tiles, he put some thorns at the bottom, not for the purpose of supporting the drain, but simply to intercept an escape of mould. By this simple means he secured a most effective drainage. The drains had now been in existence for eight years, and were still in the most perfect condition. He mentioned these facts because he considered that they had an important bearing upon the question of expense, and showed that there were cases in strong retentive clays in which land might be effectually drained without resorting to the use of tiles.

Mr. MECHI: Is yours brick-earth or tile-earth?

Mr. HATFIELD: Brick-earth.

Mr. COUSSMAKER, (of Westwood, Guildford,) was glad to find that there was one point at all events upon which they were agreed, namely, that no one system was generally applicable to all soils alike. He knew nothing about springy, and little about porous soils; but upon strong clay soils his idea was, that the best system was that which got rid of the water in the quickest manner. A moderate depth, therefore, at as frequent intervals as convenient, was what he considered best. He had no objection to increase the depth—they would drain the soil perhaps equally well—supposing the expense of the operation was not an object, but it was money thrown away to increase the depth beyond a certain distance, or to suppose that by so doing they could place the drains further apart. His practice had been to go about seven yards apart and about thirty inches deep; he was glad to find Mr. Mechi agreeing with him. With regard to laying the land flat where the soil was composed of clay, it was not desirable. He had seen the system fail, and would on no account adopt it himself; as the cultivation of the land could not in that case be performed without considerable treading of the horses, which

ought most carefully to be avolded; but by laying ground in 7½ feet lands the horses could be confined entirely to the furrows, also the land dried faster.

Mr. W. BENNETT (Cambridge), after some experience in draining various descriptions of land, had arrived at conclusions similar to those of Mr. Nesbit. He was also pleased with the observations of Mr. Mechi, on account of the frankness with which they were spoken, and readily acknowledged the services which that gentleman had rendered to the cause of agriculture by his experiments in farming, and by directing attention to masters which were of interest and importance to the agricultural community (Hear, hear). He thought, however, that his friend was certainly wrong in putting gravel at the bottom of his drains and tiles at the top (laughter). Upon the whole, he (Mr. Bennett) was of opinion that they were likely to come to a safe conclusion to-night; and that was, that upon strong clays it was useless to go tremendous depths, involving an expenditure that could never be repaid the farmer; and that drains varying from five to seven yards apart, with a moderate depth, so as secure them from damage, say from two-and-a-half to three feet, were most desirable upon retentive soils. He had farmed some of the strongest land in England for a considerable portion of his life, and these observations were the result of his experience. For his ow part, he thought the club was much indebted to the professional drainers who had expressed their opinions to-night. Although he could not go the "whole hog" with Mr. Denton, yet the views of that gentleman well deserved consideration; and he could not doubt that the discussion would prove of great service to the agricultural classes generally.

Mr. TRETHEWY (of Silsoe, Beds) said the subject had taken exactly the turn that he expected it would take. Although Mr. Nesbit gave notice that he would treat on the mechanical and chemical principles connected with the soil, the discussion very quietly diverged into practice—a result which might have been anticipated in the case of a meeting of practical agriculturists. One great point which had occupied their attention was the depth of drains. He did not himself advocate either deep draining or shallow draining as a system, but from what he had heard that evening, he supposed he might infer that the shallow drainers were those who went three feet deep and less, and the deep drainers those who went further below the surface. Now, his idea of draining was not only to get rid of the water, but also to act upon the surface and the substance of the soil as much as possible. (Hear, hear.) In draining for corn lands and for grass lands there were different objects to be kept in view. In the case of grass lands they wanted to keep up a continuous verdure; but that was not the case as regarded arable lands, and he maintained that the latter required to be more drained than the former. It was well known that the roots of wheat would descend to a very great depth. He had never witnessed it himself, but he had been told on good authority that the roots could sometimes be traced four feet below the surface. (A voice: "More than that.") If the roots of the soil did really descend so low, it should be made a great object in drainage to prepare the soil for the sustenance of the wheat plant. He did not fully subscribe to the doctrine that depth did not at all depend on distance. He held that it did depend on distance to a certain extent; conceiving that if they went twelve yards apart they must generally drain deeper than if they went only four yards apart. Some remarks had been made about Elkington's system; such things looked very pretty in theory, but he must declare that in his experience he had never been able to hit upon the right mark. He remembered one instance in particular in which he could not do that. There was a bog at the bottom of a sandhill. On one side of the road was a wild sandhill: immediately below it was a bog. He thought that if he cut a very deep drain at the junction of the sandhill and the bog, he should thereby cure the bog; but he did not. He was obliged to go through the bog, in the direction of the hill, and then he did cure it. He did not know whether or not the geological strata in his district were similar to the strata of districts in which Elkington's system was said to have answered; but this he did not know, that he had tried that system three or four times, and was determined that he would never try it again. (Hear, hear.) Swallow-holes had been referred to. He held that in many instances it was impossible to do without them. No one could suppose that swallow-holes were applicable to clay lands; but there were certain descriptions of soil—for example, there was a case near the Tetbury road, in the vicinity of Cirencester—where by adopting that mode of proceeding you get rid of an immense quantity of water at a very small expense; whereas the obtaining an outfall in the usual manner would involve a large expenditure.

Mr. WOOD (of Ockley, Sussex) said he had the misfortune to farm that description of soil which Mr. Nesbit regarded as a *bona fide* clay, and he had expended a good deal of money in draining land which required quite 50 per cent. of sand to bring it into a fit state to make a brick. What Mr. Nesbit had pointed out with respect to hilly land corresponded with his own experience. If in putting a drain across the slope you were to place it under a stratum of clay, you would catch none of the water; whereas if you were to place it above, you would catch all. The great difficulty was to find the exact position; and, therefore, by going down the slope and cutting across, or through the strata, you generally would let off the water in the most effectual manner. The discussion had turned naturally more upon the practice than upon the mechanical and chemical principles of draining. As regarded diatance, he certainly thought that in the description of soil of which he had spoken, the deeper drains would carry wider than shallow ones. He had found that in cases which, owing to a hollow perhaps in the ground, he had not been able to go so deep as in other places, the ground had not been made so dry. He had drained at distances of one rod apart, and that was as close as he felt justified in going, with the prospect of wheat at 40s. per qr.

A MEMBER: What is your depth?

Mr. Wood continued: When he commenced eight or ten years ago, a depth of two feet was advocated by one party, and a depth of four feet by another. Being of a prudent turn of mind, he thought he would adopt the middle course, and accordingly he adopted three feet (laughter). In cases in which he had to cross a flat, he had been prevented from going more than two feet or even eighteen inches deep to preserve a fall, and in such cases he had always doubled the number of drains.

Mr. MECHI: You have not drained four feet.

Mr. WOOD said he had done a little, but it was on grass lands. He had learned from Mr. Nesbit and others, that there are some beneficial results to be secured through the passage of rain through the soil, and he was very much opposed to carrying it away by means of surface furrows. Besides, having had doubts about the best depths for his drains, he had entertained doubts about the proper distances between them. He did not find his land too well drained with the drains at a rod apart, that is 16½ feet. He found the soil wettest farthest from the drains, and he also found that the wheat above the drains and nearest to them looked the best. If his drains were placed eighth feet apart the change would, he believed, be very beneficial to him. As regarded depth, if he could go four feet at the same expense as three feet he should prefer that depth.

Mr. W. SHAW (of Coton, Northampton) said, viewing the question as a money question, he had no hesitation in saying that three drains at four feet were more beneficial than four drains at three feet. He wished to state that emphatically, as his decided opinion in regard to depth.

Mr. JOHN PARKINSON (of Knapthorpe, Notts) said he had found, from experience with regard to drainage, that practice was far more valuable than theory. He did not refer now to his own practice; what he alluded to was draining done thirty years ago by his predecessor. That drainage was under two feet six inches deep. It was done at the time when tiles were first introduced into Nottinghamshire. The person who put them on was very much laughed at, at the time, for burying his money; but he persevered, and his neighbours first became convinced that he was right in the year 1829, when he and his brother were the only persons in the district who had not a rotten sheep. The land was a strong red clay; the drains were put in under the old furrows, tenacious as they were, about eighteen or twenty inches deep, and the lands having been gradually levelled from the high ridges, the depth of the drains was now about two feet six inches. That land was as well drained as any land could be, even though it were drained four feet deep. To illustrate this he might refer to an article, with which they were no doubt all familiar, which had appeared in the pages of the Royal Agricultural Society's Journal, and which was written by Mr. Milward. That gentleman stated that he had drained a twelve-acre field, two feet, two and a-half

feet, and four feet. The outfalls of all the drains were visible, so that anyone could at once see in which the rains which had fallen ran first; and having been there frequently himself, he could never perceive very much difference in point of speed between the different drains. No doubt some difference would be discovered on a careful examination, but he had not perceived any. The effect of the drainage as a whole was such that no one could tell where the shallow drainage was, and where the deep drainage was—the soil was equally productive; and he concluded therefore, in this case, that, as shallow drainage involved the least expense, it was preferable to deep drainage.

A MEMBER: You have been speaking of grass lands only.

Mr. PARKINSON continued: The land to which he had been alluding was all ploughed land. He could tell Mr. Denton of an instance in which Elkington's system of draining had been put in operation within the last few years. There was a large tract of boggy land, the outbreak of Sherwood Forest springs, which was attempted to be drained for a number of years, in a great variety of ways, the attempts all failing, because those who made them could not get beneath the water. Mr. Mildward happened to get hold of some land in the vicinity which commanded this, though it did not appear at first to be connected with it; and when a drain had been opened there, the water rushed out with great force, the result being that the land in question was completely drained, on the Elkington system.

Mons. TREHONNAIS thought the practical conclusion to be arrived at, as the result of that evening's discussion, was—that no one principle or system of drainage should he dogmetically proclaimed as applicable to all descriptions of lands (Hear, hear). The value of the discussion arose chiefly from the fact that those who took part in it represented different parts of England, with all their differences of geological formation and soil; while he himself appeared there to represent France in this matter. It could not fail to be advantageous to elicit the opinions of practical men with regard to the drainage of the land with which they had to deal. Mr. Wood had found that, in the case of high lands, the best course was to lay the drain up-hill. His own practice was the reverse of this. On his farm in France, he was engaged in extensive draining operations on such land last winter. He was obliged to lay his drains perpendicularly to the dip of the land, having been taught by observation and experience that the other practice would not prove satisfactory. Having devoted attention for some years to what he might term scientific drainage, he contended that the aid of science was by no means to be despised. Scientific principles like those laid down by Mr. Nesbit were, in his opinion, very useful guides in the practical operations of drainage. In this matter, as in many others, what was especially needed was, a combination of science with practice; and this would, he believed, prevent a vast amount of useless expenditure, and labour in vain.

Mr. THOMAS (of Bletsoe) said: I would not trouble you at this late hour after so much has been said on the subject had not my own experience (which has extended over a period exceeding twenty-five years) led me to a different conclusion from that of several of the previous speakers, in regard to draining *stiff clays*. I am of opinion that three feet is a depth sufficient in such lands; a less depth would be liable to injury from cart-wheels and other casualties. Drains four feet deep would not be so effective in such soils placed at a greater distance apart; and the advantages arising from drains of such a depth would not compensate for the extra expense or cost. However, on soils of a different character—for instance, mixed soils, it would be desirable to go four feet, or even more; having myself drained such soils to the extent of five, and in a few instances as much as six feet. It is, therefore, difficult to lay down any system as a general rule; and I am glad to find that my practical experience has been confirmed by much that has been advanced by Mr. Nisbet on the subject.

Mr. C. M. BIDWELL (Ely) said, having been present at many discussions on the subject of drainage, he was very glad, as a practical man, to see that the question of deep drainage *versus* shallow drainage was being reduced to a very narrow compass, namely, between three feet and three feet four inches, and four feet. He thought they were nearly all progressing more and more towards four feet. He had seen a great deal of draining done at that depth, and he did not know a single instance connected with strong clay lands in which experience was not in favour of a depth of four feet. He had been over a farm in Sussex that day, in the neighbourhood of Mr. Wood's farm; and in that case the drainage was carried to the depth which he had mentioned, and the result was highly satisfactory. He hoped that in a few years they would all adopt a minimum depth of four feet.

Mons. TREHONNAIS hoped he should be allowed to supply an omission in the remarks which had fallen from him. He had intended to allude to the loss which the agriculturists both of England and France had sustained in the lamented death of the late Mr. Trimmer. (Hear, hear.) During a great part of his life that gentleman bestowed more attention on the subject of drainage than almost any one in that room; and he thought he rightly interpreted the feelings of all the members of that club when he said that they regretted the loss sustained by geology and agriculture in the death of that distinguished man. (Hear, hear.)

Mr. C. STOKES (Kingston, Kegworth) had seen a good deal of draining, and of the effects produced by draining in the counties of Nottingham, Leicester, and Derby, and he must testify that in the last five-and-twenty years there had been a very great improvement there in that respect. When they first began to drain in that part of the country, thirty or forty years ago, they put tiles in the ground from 12 to 18 inches deep, and in a very few years this proved to be of no use. Mr. Parkes' system was then introduced; about six or seven hundred acres were drained on this system, and he had not seen a single case of failure. It was strong land, but not entirely clay, there being a good deal of marl. He did not know a single failure at a depth of four feet. When that system was first adopted, there was hardly a person in the neighbourhood who did not laugh at it; now no one scarcely drained at a depth less than four feet. He was satisfied that it was a great mistake to suppose that water would not percolate through the soil at that depth. Let the air get into the land, by making the drains, and that would make a way for the water. He did not wish to find fault with what had fallen from gentlemen who came from other parts of the kingdom; but as regarded that part of the country in which he lived, he was convinced that no practice answered so well as that which he had mentioned. (Hear, hear.) One word with regard to what had been said by Mr. Thomas about the over draining of grass lands. He fully admitted that for a year or two grass lands might appear to have been over-drained, the water having been taken away which previously tended to produce a coarse kind of grasses. The remedy for this, however, was to put some manure on the land; and when that had been done judiciously, the advantage of draining would soon be visible in the production of grasses of a better description. (Hear, hear.) A friend of his, who drained some grass lands soon afterwards, remarked to him that it was injured. The next year he (Mr. Stokes) asked him if he still considered it injured by draining. "Oh, no," was the reply; "I never saw finer grass land in my life." (Hear, hear.) If the draining of grass land were followed by a proper application of manure, the land would soon come round again. In conclusion, he would observe that they had not heard any gentleman say that evening, that having put his drain pipes four feet deep, he had been compelled to pull them out again. On the other hand, he had himself drained at a depth of two feet and a-half, and the result was most unsatisfactory.

Mr. B. DENTON could not help expressing his concurrence in the remarks of Mons. Trehonnais, respecting the death of Mr. Trimmer. He had been frequently opposed to Mr. Trimmer in his views relating to drainage, but there was no man for whose exertions and character he entertained a greater respect.

Mr. G. H. RAMSAY (Newcastle-on-Tyne) must express his dissent from the notion which appeared to exist in the minds of some practical, farmers that there was something like opposition between practice and theory. He might point to the most practical man in that room, and predicate of him, that before he became a practical man, as regarded drainage, he was to some extent a theorist (Hear, hear). He thought it was high time to do away with the foolish distinction which was often drawn between theory and practice. What they had to aim at, in seeking perfection in drainage, was the proper combination of practice and theory (Hear, hear). They did not ask Mr. Nesbit how they were to use a spade or to dig their drains; they looked to him for the enunciation of scientific principles, and all they had to do was to consider the general rules which he had laid down; he was not so foolish

as to expect them implicitly to follow them under all circumstances (Hear, hear). If they began at practice without theory, they would all find, ultimately, that they had begun at the wrong end. There was one view of this question which he had not heard that evening. The matter had been discussed as if the farmers drained all the land of the country; whereas, in fact, a great deal of draining was done by the owners of land. If, indeed, a farmer had plenty of capital, there was no reason why he should not avail himself of it, under proper conditions, to effect the drainage of his land; but they all knew very well that, as regarded the country generally, landlords were called upon to aid with their money in drainage operations as well as in providing proper buildings on the farms (Hear, hear). This was not, therefore, solely a farmer's question; but he believed that landlords in general were open to conviction, and that if the work of drainage were slow, it would also be sure. He congratulated the club on the intelligence which had been displayed that evening in regard to drainage, and considered the tone of the discussion an indication that the club would continue to be—what it deserved to be—the leading agricultural club of the kingdom (Hear, hear). There was one point on which he wished to correct what appeared to him a misapprehension. One or two gentlemen had talked of the subsoil as if there were everywhere a sheet of lead just below the surface, which it was very difficult to break through. He did not know how far the observation of others agreed with his own; but he must say he never saw, in his life, a field with a uniform subsoil (Hear, hear). He never saw a field where the subsoil did not vary in depth and quality. As regarded the different systems of drainage, he would not pretend to say which system was best. He did not think the shallow system was the best, and he did not know that the deep one was the best (laughter); but in regard to that point he would simply observe that anyone who was acquainted with the science of geology would unite with him in declaring that a subsoil was not the uniform sort of thing that some appeared to imagine.

Mr. MARSHALL (of Riseholme) said, so far as his own experience enabled him to speak, he thought the ordinary drainage of land, where no great geological difficulties presented themselves, a very plain, common-sense course of proceeding. To lay the drains down the line of greatest descent; to put them in at a minimum depth of four feet, at a distance, varying according to the nature of the subsoil, of seven to ten yards apart, would in all the cases he had met with be found equal to any emergency. He had reason to feel greatly obliged to Mr. Bailey Denton for his assistance and advice in most of the draining he had carried out; and in confirmation of his (Mr. Marshall's) belief in deep drainage, he had within the last two years taken up and otherwise obliterated the entire drains upon two hundred acres of land which he had lately become possessed of, which had been put in up the furrows at a maximum depth of two feet six inches, at a distance of five yards apart, but which had proved utterly worthless as a means of drainage. He had since re-drained the whole at a minimum depth of four feet, nine yards apart, down the direct fall, across ridge and furrow, and without reference to high-backed lands or other irregularities of any kind; and he had good reason to be perfectly satisfied with what he had done. And he felt no hesitation in recommending the same system to others, where a like description of soil presents itself. By a moderately strong jointy clay, intermixed with very small sand-beds and an occasional thin stratum of stone, varying in depth from one to three feet, and with no water to contend with but surface water, this land—from having been a wet, ungenial clay, requiring three and four horses to plough it—is now a dry strong loam, most satisfactorily ploughed by two horses, and producing as fine crops of turnips as can be seen anywhere, and without any difficulty whatever in ordinary seasons as to eating them upon the land. He would add that he had known others in his own immediate neighbourhood who had taken up miles of shallow drains, and replaced them by deep ones; but he never yet heard of any one who had ever taken up a deep drain and replaced it by a shallow one. His draining cost 65s. per acre, besides the pipes—say about 18,000, 1¾ inch, at 18s. per thousand.

The CHAIRMAN said, after the very long discussion which had taken place, he would not trouble them with many observations. He must, however, make one remark in confirmation of the opinion expressed by Mr. Stokes, with respect to the apparent injury sustained by grass-lands from draining He quite agreed with that gentleman that the injury was more apparent than real (Hear, hear). Of course, when grass-lands had been drained, a certain amount of coarse herbage would disappear, in consequence of the removal of the water. But they must wait patiently till better and more nourishing grasses took their place. That that operation would be assisted by a good coat of dung there could be no question (Hear, hear), but that Nature herself would perform the work, if they only had patience, was equally clear. He had seen this result in the cases of grass-lands which had been drained by himself and others. With respect to the depth of drains, he thought there could be no positive and invariable rule; but every person should, before he began to drain, try to find out where the water was, and then make his drain of the requisite depth (Hear, hear). His own opinion, however, was decidedly in favour of deep drains; and he believed that where errors had been committed they had been more on the side of shallow drains than of deep ones (Hear, hear). He would now call upon Mr. Nesbit to reply.

Mr. NESBIT said he had very little to say in reply to the observations which had fallen from the various speakers. He must confess that he had expected to meet with much more opposition than he had done; though all he contemplated doing, in his opening address, was to state a few scientific facts and principles relative to the nature of the soil. He anticipated that he would be overwhelmed by the shallow-drainers, but the principal attack had come from the deep-drainers. He took neither one side of the question nor the other; but he must say that he could hardly conceive any person, who considered how great was the variety of soils to be drained, maintaining that any one uniform depth would answer best universally. If there were any such person, he was certainly much stronger in self-will than he (Mr. Nesbit) was. Mr. Baker made a remark with respect to the nature of the experiments presented, which indicated that he scarcely understood their object. In the different specimens of soil which he had exhibited, his design was to represent, in a few seconds, what would probably take place on their farms in several days. He was very much astonished that Mr. Bailey Denton appeared never to have heard that a shallow drain would sometimes run before a deep one. He had a work of Mr. Denton's in his hand, which he had carefully studied, and which contained a reference to Lord Wharncliffe's system of drainage. It was stated that Lord Wharncliffe having drained four feet deep, and this not having been found to answer, he then put shallow between deep drains, and that did answer. Again, the following is an extract from a letter of Lord Fortescue to his son in reference to the same point:—"I may here mention that the people on our two farms say that they constantly find the two-feet drains dry after continuous dry weather; but that after heavy rains they seem to discharge much more water, in proportion to their length, than the four-feet drains, which seem to be comparatively little influenced by change of weather." All this was taken from Mr. Denton's own book, and he might cite other passages to the same effect. The only other observations which he wished to make had reference to the amount of rainfall. That must, of course, have a distinct influence on the depth and distances of drains.

Mr. Nesbit then exhibited a rain-gauge of very simple character, and explained to the meeting the manner in which it might be used, adding that the cost of such a useful instrument was only 12s. 6d. They could be obtained from Mr. Casella, of Hatton Garden.

On the motion of the Rev. Mr. James, seconded by Mr. Thomas, of Bletsoe, the following resolution was unanimously adopted—

"That in draining land, no depths of the drains can compensate for too great width of the intervals—that porous soils should be drained at depths and intervals suitable to their respective characters—but that retentive clays require drains at more moderate depths and distances."

Mr. NESBIT moved a vote of thanks to the chairman, observing that they had never had a better chairman since the club was established (cheers).

The motion was seconded by Mr. Ramsay, and carried by acclamation.

On the motion of Mr. Payne, seconded by Mr. Bullock Webster, a vote of thanks was given to Mr. Nesbit for his able introductory lecture; and with this terminated the proceedings of the evening.

THE TRADE IN THE HORNS OF ANIMALS.

The trade in animal products of a miscellaneous character is a much larger one than is generally supposed. There are several of the minor products dealt in, which offer an interesting field for inquiry, and for collecting the scattered data which can alone serve to furnish an approximate idea of the aggregate value and importance of the trade considered in a mercantile and a manufacturing point of view.

The horns of animals, for instance, wild and domestic, may seem of a very secondary importance, and yet the trade in them, home and foreign, rises to a very respectable position in the statistical returns. Indeed, the rights and privileges of the hornworkers and hornpressers have in various reigns occupied the prominent attention of the Legislature. But there is no fear in the present day "of the trade being ruined, and the business lost to the nation," as was the cry when the statutes 6 Edward IV. c. 8, and 7 James I. c. 14 were passed, forbidding the sale of horns to foreigners, and prohibiting the export of unwrought horns. We not only use up our own large home supply of horns, but import on the average fully as many more, namely, about 3,500 tons per annum.

While many of the former uses of horn for glazing purposes, for drinking-cups, for hornbooks, and for the sounding instruments of the bold forester, have passed away, other and more elegant and varied applications have been found for this plastic material, insomuch that the trade Directories show us half-a-dozen or more workers in horn, forming separate and distinct classes of the trade.

Large as the present use of horns and hoofs is, we believe that many further manufacturing purposes may be found for them, and that they will become even still more important than they now are in a commercial point of view.

Although the largest trade application of horn is for knife-handles, combs, and umbrella tops, still the other uses are also extensive, and as numerous as the varieties of horn which come into the market, or bristle on the head of the animals characterized by this frontal appendage. Ox, buffalo, and deer horns are those mostly worked up; but the horn of the rhinoceros, ram, and some few other animals, are also employed to a limited extent. For the spiral tube of the antelope, little or no commercial use seems yet to have been found.

The study of the composition, formation, and growth of horn is an interesting one, and well deserving of careful investigation, in view of the manufacturing purposes to which this substance may be applied. In common parlance, any hard body projecting from the head, terminating in a free, unopposed point, and serviceable as a weapon, is called a "horn." But the composition of these differ materially. Professor Owen well observes, "Even the weapons to which the term 'horn' is properly or technically applied consist of very different substances, and belong to two organic systems, as distinct from each other as both are from the teeth. Thus the horns of deer consist of bone, and are processes of the frontal bone; those of the giraffe are independent bones or 'epiphyses,' covered by hairy skin; those of oxen, sheep, and antelopes are 'apophyses' of the frontal bone, covered by the corium, and by a sheath of true horny material; those of the prong-horned antelope consist at their basis of bony processes, covered by hairy skin, and are covered by horny sheaths in the rest of their extent. They thus combine the character of those of the giraffe and ordinary antelope, together with the expanded and branched form of the antlers of deer. Only the horns of the rhinoceros are composed wholly of horny matter, and this is disposed in longitudinal fibres; so that the horn seems rather to consist of coarse bristles compactly matted together in the form of a more or less elongated sub-compressed cone."

The horn of the rhinoceros, like its skin, when polished and in thin layers, is as transparent and mottled as tortoise-shell. These horns are often obtained 2 feet long, and 10 inches in diameter. In India they have the reputation among the Mohammedans of being an antidote to poison; and in older times they were the fashionable scent and oil-bottles of the Roman dames.

It is commonly believed that the horns of the ox acquire an additional ring every year after the third, but the addition of annuli is far from being annual in other species. Many rings are gained in one year's growth of the ram's horns, and in those of the ring-horned antelope. The length of the horn forms a distinguishing characteristic in some breeds of cattle; but whatever improvements may have been effected in the form and character of the carcase, by the modification of food and habits, it does not appear that we have been able to superinduce any improvement or alteration in the size or texture of the horns. Indeed, the horns of the wild animals would seem to be more prominent than in the domesticated races.

The immense horns of the African or Cape buffalo, of the Java buffalo, and the Arnee buffalo of India, are the most valuable, and the extent of the trade in this class of horns may be estimated from the fact that about one million buffalo horns were shipped from the port of Madras last year. As we derive two-thirds of our foreign supply of horns from the East Indies, it is not improbable that the existing disturbances may cause a deficiency in the shipments thence, owing to the interruption of internal communication, and the withdrawal of large masses of the population from their ordinary peaceful occupation of collecting and bringing in the horns to the mercantile houses.

South America (chiefly Brazil and the Argentine Republic) furnishes us with a considerable quantity of ox horns, and we also receive several hundred tons a year from the United States. For buffalo and stag horns we are mainly dependent on India: of the former we import fully 1,400 tons per annum. Averaging these at 1,400 horns to the ton, this would show a mortality of a million buffaloes a year, besides what may be locally used up, or sent to America and the European ports. Of deer horns the Sheffield cutlers and others work up about 400 tons, chiefly derived from Ceylon and the peninsula of India. The "fall" from at least 300,000 head of deer is required to supply this quantity.

Of the aggregate annual quantity of horns entering the market, estimated at 6,400 tons, about one-fifth is manufactured into combs, valued at from £300,000 to £400,000; a large quantity is worked up into knife and cutlass handles; while there are many other miscellaneous uses, in shoe horns, scoops, drinking horns, &c. The waste pieces of stag horn are boiled for size in the cloth-making districts; and the pith or slough of other horns and hoofs is crushed for tillage, when

light, and thus fit. The heavier portion is converted into prussiate of potash and Prussian blue, of which about 10 tons are made weekly in Sheffield from the waste products.

The hoofs of cattle, being composed of the same material as horn, are used for manufacturing purposes to a small extent; and besides our home supply, we import about £4,000 to £5,000 in value. They are pressed out into combs and horn buttons; but the greater part finds its way to the boilers of the glue maker, and to the manufactory of the chemist, who work them up, with other animal refuse, into prussiates.

As a fertilizer, horn cuttings and shavings are very useful when they can be obtained in any quantity.

The composition of stag horn most resembles bone, while the horns of black contain fully 90 per cent. of albuminous matter. It is difficult to estimate what quantity of the horns used up in manufactures, or of the slaughtered animals, are returned to the soil in the shape of manure, in common with the numerous other animal and vegetable products. Mr. Braithwaite Poole, in his Statistics of British Commerce, calculates that the animal manures used yearly amount to about ninety million tons, besides fat, blood, garbage, &c.

MODES OF ENTERING AND QUITTING FARMS, WITH SUGGESTIONS FOR THEIR IMPROVEMENT.

[A PAPER READ BY MR. ROBERT BAKER, OF WRITTLE, TO THE MEMBERS OF THE FARINGDON BOOK SOCIETY, ON TUESDAY, DECEMBER 1ST, LORD BARRINGTON IN THE CHAIR; LORD RADNOR AND ABOUT A HUNDRED OTHER GENTLEMEN BEING PRESENT.]

The growing importance of agriculture, and the rapid strides it has of late made, demand our utmost consideration; for when we consider that with a limited area we have a largely increasing population augmenting yearly, it becomes a subject of the greatest national importance to ascertain to what extent the ordinary modes in operation for the production of bread-corn and meat are beneficial, and more especially whether the present system of tenure is the best calculated to attain that desirable object; for, as Adam Smith asserts what few will be disposed to attempt to disprove, that "Labour is wealth, "thus it requires no laboured argument to prove that the large amount paid annually for wheat might be saved to the country, at any rate to such an extent as we by increased exertions and application of means might be able to effect it; and as the enterprise and energy of the British farmer can be sufficiently estimated, it will be well next to inquire what other obstacles exist to retard it; and, upon a due consideration of the subject, to point out a remedy so far as it may appear requisite for the accomplishment of such purpose.

As it will be of too extensive a character, upon an occasion like the present, to attempt an investigation of the question in all its bearings, and as the discussion of this evening is appointed for that portion only which relates to the customs existing in different portions of the kingdom, upon the change of tenancy of farms, as well as upon what period of the year is most suitable, I shall at once discard any elaborate investigation of the customs now prevailing throughout this kingdom, but proceed at once to investigate the subject upon its broad principle, with a view rather to show which really ought to prevail, than to discuss the anomalous conditions that at present exist, the remains now of a period long passed away, and at the present time totally inadequate to the advanced requirements of the age.

If we endeavour to trace back to a very distant period, we shall find that the first tenants rendered payment of rent to the lords of the soil, for the most part, in labour or in kind. Most of the college leases, even to the present day, retain many of the conditions that existed centuries before our time; still receiving their rents in grain, malt, and money, or having the amount of rent upon the average prices of corn and malt for the year current to which they apply. In process of time rents became entirely paid in money; and corn leases for terms of years have become so modified, as to meet the fluctuations that arise in the value of produce. This system has been attended with the most beneficial results, as it has enabled landlords to demise their estates for terms of years, without a liability of becoming seriously injured in case the price of wheat and grain, from unforeseen circumstances, should rise to higher prices than had been contemplated. It enables a tenant also to take land upon like tenure, with a certainty of continuance as tenant under circumstances of depression in the prices of corn, inasmuch as his rent will fluctuate in amount proportionally with the prices he obtains; and thus his rent will at all times more truly represent the value of land, in relation to the value of produce, than by any fixed money payment that could be devised.

At a subsequent period it was found necessary to establish a principle to protect the landlord from being seriously injured by the ignorance or wilfulness of a bad tenant; and the ancient law, based upon antecedent customs, afterwards became modified as the advancing progress of the age required.

In our time, however, such has not been the case. The old law prevails to such an extent as to become injurious to an improving tenant, whilst it has not sufficiently restrained a bad one. Conditions in leases, therefore, have more or less been resorted to, as the only means of defining what custom had failed doing, and thereby fixing the mode of cultivation to be pursued, and determining the mode of entering upon and quitting of farms.

In the first instance the custom was to fix the mode of entering in such manner that the largest amount of payment might be exacted from the tenant by valuation, upon his entering upon the farm. This was done mainly for the purpose of insuring an amount of capital to be paid down, which, from the nature of the investment, could not be extracted by the tenant until at the immediate time of his quitting the occupation, thereby securing the rent to the landlord to the amount of claim that the tenant would have upon the farm at quitting. This system, however, carried its own result to the end of the term: it was, in fact, equivalent to depriving the tenant of the capital he embarked throughout his entire lease, and thus depriving him of any advantages, either by return of interest or by the application of the capital to the improvement of the soil.

It was obvious, however, then, as at the present time, that the farmer ought to be protected from waste, more especially by the tenant selling off the hay and straw without consuming it by horses or cattle, and without

bringing on any equivalent in manure; and as the latter could not be formerly obtained to a sufficient extent to maintain the farm in good heart, a direct prohibition through the term to the selling any portion became the necessary and established custom of the kingdom, with partial exceptions only, where farms also were situated near large towns, when the tenants were allowed to sell wheat straw and hay, upon bringing back upon the farm an equivalent in purchased manure. This, by degrees, has become in many instances a pernicious custom upon estates. The tenants, from having paid the market value of the wheat straw and hay upon entering, also claim it upon quitting their respective farms. In other cases, and upon custom widely extended, the outgoing tenant is allowed the *bite*, or foddering, as it is termed, of the straw or hay, or is paid the value of such bite or foddering value by the incoming tenant, either at its money value, as estimated upon half the amount of marketable value, or by the outgoing tenant paying the expense of thrashing out the crop and carting the grain to a distance of ten miles, as the equivalent of such foddering value.

This mode appears a very rational one, and is, perhaps, the best hitherto propounded, as it enables the incoming tenant at once to take entire possession of the farm, and to turn the straw and hay to the best account, as well as enabling the outgoing tenant to proceed at once to his new occupation upon the same conditions.

The next consideration will be the manure, which, in all cases, ought to be left for the landlord, or his representative (the incoming tenant), by valuation, including also the expense incurred by the outgoing tenant in throwing it into heaps, or carting it out to its final destination for direct incorporation with the soil, or in heaps for subsequent application.

The next item usually paid for, and with due reason, is the amount of labour bestowed upon the land under tillage for the production of green cattle crops, or for the purpose only of cleaning and fallowing and draining the land. These heads premised, I shall at once proceed to show their various bearings, and to point out how far they become beneficial, as well as to discuss those points bearing immediately upon the question under notice for this evening's discussion.

In pursuing the subject, I consider it the best mode at once to assume that the estate is in hand, and unshackled by any previous fixed customs interfering with the system to be propounded in what I shall have in continuation to offer; and, therefore, discarding all other modes of entry and occupation, many of which are notorious for their defects, I shall, in discussing the subject, endeavour to simplify the mode of entering and quitting farms, thus keeping the principle I adverted to in the outset, of not charging the tenant with unnecessary payments, so far as can consistently be avoided without damaging the landlord, or preventing him resuming the occupation of his estate without difficulty or constraint.

My chief aim will be to show how far a system may be applied, so as to leave the capital of the tenant unfettered, but also to secure a continuous improvement of an estate, in place of those customs that secure it only up to a certain period of an occupation, and, afterwards, as it approaches its termination, allow it to become yearly withdrawn by the tenant—so much so, that, by the time of its closing, all the capital he had first invested in improving the farm becomes withdrawn, so that at the last it is frequently reduced to a worse position, as regards its state of cultivation, than it was found in at the time of entry upon the occupation. To obtain a desirable result of the nature I have propounded, I confess many obstacles present themselves; the customs that have prevailed upon estates being difficult to supersede, although those customs, for the most part, do not secure any object either desirable or beneficial, but, having for many years been practised, have become as it were rent-charges upon the estate to which they apply, payable every time a farm is transferred from tenant to tenant in perpetuity, and almost as difficult to be got rid of as even the tithe rent-charge itself, or parochial charges of any other description, unless by way of purchase at their estimated values. Whenever such payments extend to many subjects, so as to swell the amount of valuation beyond an ordinary and necessary amount, they become a severe tax upon the incoming tenant; and when they appertain to the value of the manure, through two or three years, in the shape of dressings, half-dressings, &c., as well as to rent, rates, tithe rent-charge, or parish and national rates, they uselessly swell the amount of the valuations, to the great injury of the tenants, who thereby become deprived of the benefit of the capital so invested throughout the whole period of their term or yearly occupation, as well as inflicting upon the landlord a very heavy charge in perpetuity upon his estate, and occasioning him great inconvenience whenever his farms again may chance to fall into his hands.

To obviate these evils on the one hand, and to secure the continuance of good farming to the end of the lease on the other, will occupy my attention in the task I have now undertaken; I therefore must crave your indulgence, and, although I may only partially succeed, I shall probably advance suggestions that more able and talented individuals will hereafter turn to better account, and which at some future period may obtain that degree of perfection which at my advanced period of life I can hardly expect myself to attain.

I will now proceed to investigate the period best adapted for the change of tenancy upon farms, the usual periods being New Michaelmas and Lady-day; and wherever the occupation consists principally of arable land, no doubt can exist that Michaelmas is the time most beneficial to both incoming and outgoing tenant, as it is the climax of the year's proceedings on the one hand and their commencement on the other, and with certain modifications may be made fully to embrace every object desirable for an outgoing and an incoming tenant to attain. In some districts, however, the harvest cannot be concluded by that period. In such cases the occupation must partly be retained and partly given up, still considering the quarterly day of New Michaelmas as the one best suited for the commencement of the year's tenancy, as well as for carrying on the necessary work upon the farm. I would premise, however, that the incoming tenant should have possession of those portions of the farm from which the grain crops have been cleared at an earlier day, and as soon as he may require them after they have been so cleared, and which should be allowed from one week after such clearing.

We will at once suppose that the landlord, being desirous to assist the incoming tenant, commences by allowing him, without prejudice, to take possession of such portions of the farm, for the purpose of fallowing, putting-in vetches or rye, or preparing for root crops, immediately after the fields have been cleared, due time being allowed for feeding them with sheep and swine—say fourteen days at furthest—from the time of clearing. He should also allow him to plough and till the fallowed land, if the tenant is desirous of doing so, and he declines himself further to do so at the time required; in fact, a virtual possession should be allowed upon portions of the farm previous to Michaelmas day, after the preceding crops have been removed.

At or previous to Michaelma-sday the valuation should be made, and which valuation should include all acts of husbandry executed by the outgoing tenant, of which he may not have derived any benefit, and from which he may only have derived a benefit in part.

In the first place, the necessary ploughings and tillages given to land since the preceding Michaelmas, when a green crop has not been taken. This portion of the valuation will include the ploughings and tillings of all lands considered as fallows, or producing green crops, as tares, rye, and such crops as are consumed by cattle during the preceding summer, and of all land prepared for the growth of roots, as mangel wurzel, Swede and common turnips, rape, cabbages, and crops of a like description. The course of cultivation of these crops, in addition to the ploughings and tillings as before stated, must be estimated and paid for at a such a sum as they may be valued at, without reference to the value of the crops, unless any defective management has produced such a result, and which must be determined by the valuers appointed.

In the next place, the manure ought to be valued at what it may be worth, taking the expenditure for oil-cake and corn in the preceding year into consideration, a fair proportion of such corn or oil-cake to be allowed over and above the ordinary value of the dung, to the extent of one-fifth of the entire cost only, upon proper vouchers being produced of its having been consumed upon the farm from the preceding Michaelmas, and to insure good cultivation to the last an allowance upon the oil-cake consumed the preceding year to the extent of twenty per cent., in my opinion, oxght to be allowed.

We have not treated of manure produced by extraordinary means, and it remains only to show that the ordinary manure produced upon the farm, and not applied to the production of grain crops, should or should not be paid for, together with the labour of carrying out and preparing, as well as carting and spreading upon the land, be paid for according to its value, which must depend upon the number of cattle and horses kept upon it, and the description of food upon which they have been fed; in no instance, however, should any manure be paid for unless made since the preceding Michaelmas, so in fact that the manure only of one year should in any case be valued, nor any portion be valued if a grain crop had been since taken from the land to which it had been applied.

We now come to an important item—the straw and hay of the previous year's crop. As regards the former, it ought to be considered as the property of the landlord, and not removable from the estate at the expiration of the term; the tenant having an interest therein by feeding it, and for which he ought to be compensated. Thus in many counties is it computed by the cost of thrashing and carting out the crop, the former being paid for by the incoming tenant, at such a sum per qr. as the valuers may agree upon, the incoming tenant carting out the grain a distance not exceeding ten miles in addition: in other cases the wheat straw being estimated at per ton, at its market value at the barn, half that price is paid; barley being taken at two-thirds; and oats, if well harvested, at three-fourths of the value; beans and peas at half that amount. Supposing, therefore, that the wheat straw is worth 24s. per ton, 12s. would be paid as the feeding value; barley at two-thirds, or 8s.; oats at 9s.; and beans and peas at 6s.: if measured by the quarter, say wheat thrashing 2s. 6d. and carrying 1s. per quarter, this at four quarters per acre will be 14s.; barley, at 2s. 6d. and carting 8d., at five quarters, 11s. 8d.; beans, four quarters, at 1s. 6d. and carting 1s., 10s. per acre, and so on. This is one of the most ready modes of settling, and is very fair, as the incoming tenant, having the horses upon the farm, is enabled to carry out the corn without much inconvenience.

The hay is the next consideration. The market value being found, one-third is deducted to meet the cost of marketing and carting out, and bringing back a suitable quantity of manure if sold, an allowance of one-third partly meeting the question.

These items will be found to comprise all the subjects that ought fairly to be valued, and which constitute the ordinary valuation. To provide for the well-cultivation of the farm to the end of the term, permanent improvements, carried out during the preceding four years, ought to be allowed and paid for. Draining, if done by the tenant within that period, should be paid for to half the cost; and so of any like permanent improvement, such as would extend throughout an entire term of fourteen years. It would, however, not be desirable to burden the landlord, on the one hand, with too heavy payments of this nature; but the tenant should, notwithstanding, be partly compensated by way of inducement to proceed, so that, either event occurring of quitting or continuing the occupation of the farm, he may be placed in such a position that the least possible loss should accrue to himself or to the farmer.

I believe I have now adverted to the principal items ordinarily coming under valuation, and I propose, in an appendix, to show how such valuation would be best carried out, and the proportion per acre that they would carry out upon the entire farm; and it has been my study not to increase the amount of valuation beyond the actual necessity of the case, at the same time paying to such an extent as to insure equable cultivation to the end of the term.

It has happened throughout my practice to observe that tenants, farming under leases, for the most part make a large investment in the soil at first, which they gradually exhaust as they approach the termination of the lease. Now, it must be apparent to every one connected with farm management, that a farm ought to continuously advance in improvement; and, under due restrictions and a well-defined lease or custom, such would be the case. But tenants are too apt to imagine that in such event their rents would be advanced, inasmuch as the improvement remaining would be a sufficient inducement for a stranger to give an advanced rent in consequence. This certainly ought to be obviated to some extent by the mode I have recommended, and which applies only to the termination of the lease; but the restrictive covenants of the latter frequently deprive the tenant of the advantages he ought to derive under good management. I will now consider what the nature of such covenants ought to be, to insure it. It is advisabie in all cases that a lease should exist: the mere custom of a district is never sufficiently defined to admit of an occupation being carried throughout to the close in a satisfactory manner. But a lease for a long term is to some extent an unsatisfactory bargain. The landlord might suffer by parting with his estate for the period stipulated; prices might so alter as to render it a bad bargain, either for one party or the other: to obviate this, the rent should be subjected to a rise and fall in amount annually to meet the occasion. A corn rent, however, depending entirely upon the price of wheat or grain, would in many cases not operate beneficially. Grain might fall so low from the peculiar circumstances of season, blight, or other causes, as to materially affect the income of the landlord; whilst at other times it might rise so high as to affect the tenant in like manner, by calling upon him to pay a greatly increased amount of rent at a time probably when he did not derive a proportionate advance in his produce. In a work lately published, entitled "Bayldon on Valuing Rents and Tillages," as editor I treated upon this subject, and advanced in principle what in my experience I had found to work well, viz., to pay a moiety of the entire rental in money, and the other moiety to be dependent upon the price of grain. By this arrangement the fluctuation would be lessened, and neither party become

seriously affected. Another mode has been adopted, and is equally to be recommended, viz., assuming the amount of rent, with wheat upon an average for the last three years at 6s. per bushel, to be at the rate of 4 bushels or 24s. per acre, and that the average should be in the first year 7s. per bushel, by striking off the first year and adding the last, the average of the three years would be 6s. 4d. per bushel for the current year, and the rent 25s. 4d. per acre, the averages to be deduced upon the first market day in each month, as published in the *Gazette* or neighbouring market. By this mode the fluctuations in amount of rent could never be excessive in any single year, the average of three years always coming into account. Some persons, however, from prejudice, would not adopt a corn rent; but it must be obvious to every one who dispassionately investigates the subject, that rent and the value of produce ought always to be proportionate with each other. In cases where leases for long terms are objected to, a lease might be granted for a single year, and to extend from year to year until either party should give to the other notice in writing to determine the occupation. In such cases provision should be made to pay for drainage and other permanent improvements, if executed by the tenant, in proportion as such improvements might remain unexpended at the end of the occupancy.

Although upon some estates the tenants continue to farm from year to year without either agreement or lease, and a good understanding has prevailed, still it must be a most objectionable mode of proceeding, and should be avoided as far as possible, as everyone must have been convinced from the recent occurrences that have taken place that all transactions of this nature ought to be carried out as any other description of commercial transaction; and whether extending over a long or short period of time, the principle and stipulations of the bargain ought to be clearly set out and defined in writing, so as not to admit of a doubt as to the intention at the end of the term; nor would it be advisable to clog such an agreement with such stipulations as to the mode of cultivation or of quitting the farm upon so short a term. This would to some extent be useless, inasmuch as the landlord could at any time repossess himself of the farm, if he found the tenant was not cultivating it properly. At an early period, when no more manure could be obtained beyond that produced upon the farm, it was necessary to guard against straw, hay, and roots being sold; but it must be obvious, that when it might be done by the tenant, that he should not be prevented selling such descriptions of produce upon bringing back upon the farm two-thirds of their value in manure. In the case of repairs, some well-defined system ought to be adopted—admitting that the landlord finds all materials and pays half the cost of labour, the premises might be maintained in good repair and condition, so as never to cause at any one time any large expenditure, as is too generally the case, though I cannot recommend that the tenant should be exonerated altogether, and charged a proportionably higher rent. I, on the other hand, think that repairs are better done by workmen employed by the landlord, and some proportion of the outlay only be charged to the tenant, so that in any given year the sum ought not to exceed 1s. 6d. per acre. There ought to be sufficient inducement for the tenant to assist in keeping the premises in proper order, and which he would endeavour to do if called upon to pay a proportion of the cost of repairing them from year to year. The fences upon the farm should also be well repaired as soon as they require it, or the tenant be charged with the cost for his neglect.

The customs of different districts vary so greatly that I fear it would be difficult to introduce any one of general application; still by defining one least liable to objection, all others may be made to approximate in degree, and in course of time be brought more in accordance with each other.

Having digressed considerably from the subject as put down upon the card, I may be allowed to state that I have felt it necessary to state what the management, as well as the tenure, ought to be, to insure the determination of the lease upon the best and most approved principle. The landlord's interest ought to be protected to such an extent as only to prevent the tenant from taking undue advantage at the close of the term, at the same time taking precaution not to load the tenant unnecessarily upon entering the farm with payments—the less sum he has to put down at the commencement of a term, the larger amount he will have to carry on the farm throughout the entire lease. Some parties, however, object to this mode, as they state it allows persons with a small amount of capital to compete for large farms. This argument, however, has little weight. It must be obvious that the charge upon a large amount of capital produces an increased expenditure without a return annually, and therefore ought to be avoided. Landlords would do better to ascertain beforehand the capabilities of a tenant, in a monetary point of view, to take a farm, rather than to load him with heavy payments to insure it.

During my experience I have had opportunities of obtaining considerable knowledge of the working of the various modes by which tenants enter upon and quit farms, and, without egotism, I consider the system alluded to by me in the first instance as the best adapted.

The out-going tenant ought be allowed to make the fallows, if competent to do so. Horses must be kept by him for assisting in harvesting the crops, and he should have the privilege of ploughing and tilling the land until the termination of the last year of his term; the in-coming tenant, however, being allowed to come in to carry on the preparations in addition, as at first stated, and also to hoe and cultivate the root crops when considered by him to be necessary. The manure of the last year ought to be paid for in full, in proportion to the cost incurred in producing it. The hay and straw of the last year should also be paid for, as stipulated previously. The improvements of a permanent and enduring character should be also paid for in proportion to their value, when executed within a given period; and any erections, put up solely by the tenant, should be allowed to be taken away, provided the landlord refuses to pay for them, at such a price as they would be worth to remove. So all fixtures and machinery, put up by the tenant to enable him the better to carry on his pursuit, should also be allowed to be removed, if the landlord should refuse to take them by valuation.

I am quite aware of the difficulty incurred of introducing any new details; but as my object always, through life, has been to recommend such changes as would be most likely to become beneficial upon an extended scale, and, if possible, to introduce such a policy betwixt landlands and tenants as ought to exist, and, when existing, most likely to produce results of a beneficial character to themselves, but more especially to a community of persons, daily increasing, but limited to a certain space, upon which to carry out their exertions—then, I say, the utmost facility that can be afforded to them ought to be the chief aim and study of our united endeavours.

In conclusion, I may be allowed to say, that under all circumstances I think it best that the manure made in the last year of the term should be paid for. I have invariably observed whenever it is left gratis that very little remains for the in-coming tenant, and that is generally of very inferior quality; and although it creates a considerable amount of charge in the first instance, it will be found the most beneficial mode in the end.

I can only add, that I have been studious, as far as I am enabled, to state from my practice and experience what I consider the best mode of entering upon and quitting a farm. I have no private theory to carry out beyond that of benefiting a class from which I have received the utmost consideration and respect, and which it will ever be my desire to retain.

Some short discussion followed, on the subject of the lecture; and the proceedings terminated with a vote of thanks to Mr. Baker.

THE BANK CHARTER—ITS OBJECT AND EFFECT.

As many of our country readers may not be acquainted with the matters relating to the currency, and are consequently at a loss to understand the causes of the financial crisis under which the country is now passing, and which has so powerfully affected the grain as well as all other produce markets of the kingdom, the following explanation of the Bank of England Charter, and its effects upon the commerce of the country, may not be unacceptable.

By an act of parliament passed in 1819, at which time the Bank Charter was renewed, provision was made for a return to cash payments. In explanation of this we must state that in the year 1797 a crisis of a similar nature to that now existing took place, under the pressure of which the Bank of England *was compelled to suspend its payments*. Upon which, Mr. Pitt, who was then Chancellor of the Exchequer, issued an order in Council authorizing the Bank to refuse giving cash for their notes; and an act of parliament was subsequently passed declaring the one pound note and a shilling equal in value to a guinea in gold, and making bank notes a legal tender, inflicting a penalty upon any one refusing to accept them in payment for goods or otherwise.

This act continued in force until the year 1819, when, upon the question of a renewal of the Bank Charter being brought forward, the Restriction Act, as it was called, was repealed, and the Bank of England from the time the act came into operation was nominally obliged, like any other bank, to pay its notes in cash when required to do so by the holders. No restriction, however, was laid upon the Bank by this measure as to the amount of notes to be issued by it; that question being left entirely at the discretion of the directors, to manage it according to the supposed requirements of the commerce of the country.

In 1844 Sir Robert Peel found himself at the head of the Government, and the question of the renewal of the Charter of the Bank of England being again agitated in Parliament, he brought forward and carried a bill, by which material alterations were made in the management of the Bank, the principal of which were as follows:

First. That the two departments of the Bank, namely, the bank of issue, and the bank of deposit, or common banking business, should in future be kept entirely separate, so that the funds of one should not be available to, or be interfered with, by the other.

Secondly. That the issue of notes should be restricted in amount to the value of the gold held by and the securities deposited with that establishment. It is here proper to state that, by an arrangement of long standing, the capital of the Bank was taken *on loan* by the Government, for which securities are held; the Bank being allowed to issue notes to the amount.

Thirdly. The Bank was required to give a weekly instead of a quarterly account or statement of its liabilities and assets, to be made up every Saturday night, and published in the *Gazette* the following week, the two departments of issue and deposit being kept separate in the statement.

These, so far as the Bank of England was concerned are the most important arrangements provided for by the act of parliament of 1844-5. The two first, however, are those which were likely the most seriously to affect the commercial interests, according to the opinions of some of the most eminent financiers. Nor were they wrong in their conjectures; for in 1847 such was the position of the Bank, superinduced by the separation of the two departments, that the Government were compelled to issue a letter of licence to the Bank to set aside *pro tempore* the act of parliament, and make a transfer of coin from the issuing department to that of banking; the specie held by this latter on Oct. 25 being only £2,860,000, whilst the former held £5,570,000. Thus, whilst the one department of the same establishment was on the eve of stopping payment, the other was in possession of a sufficient sum to afford it relief, but was restricted by the act of parliament from doing so.

Since that period the gold-fields of California and Australia have unfolded their treasures, which have nearly all passed through this country, by which the Bank of England might have been supposed to be well supplied with bullion. And such, in fact, was the case for a time; for we find that in July, 1852, the amount of gold in the two departments was £22,040,000, being nearly half the liabilities (£46,480,000). But since that period, notwithstanding the enormous and unprecedented quantities of bullion continually since arriving at our shores, the quantity held by the Bank has as continually decreased, although to prevent it the interest upon discounts has advanced from 1½ per cent. in 1852 to 10 per cent. in 1857, at which latter period (Nov. 11th inst.) the Bank Account for the week stood as follows:

GENERAL ACCOUNT.

Liabilities.		Assets.	
Bank Stock	£14,553,000	Government Securities	£14,475,600
Rest	3,364,356	Do., do.	9,444,828
Notes in Circulation	20,183,355	Other ditto	26,113,453
Public Deposits	5,314,659	Bullion and Specie	7,170,508
Private do.	12,935,344		
7 Day Bills	853,075		
	£57,203,789		£57,203,789

And the accounts of the separate departments were as follows:

Dr. Issue Department.		Cr.	
Circulation	£20,183,355	Bullion, &c.	£6,666,065

Dr. Banking Department.		Cr.	
Liabilities	£37,020,434	Specie	£504,443

Thus, by the prohibition of the act of parliament, or the Bank Charter, the banking department was reduced to such a dilemma as not to have more bullion and specie than would have paid *three pence in the pound* had it been required to meet all its liabilities; whilst its colleague, the issue department, was in possession of

upwards of six and a-half millions, not available for its relief without an infraction of the act, amounting for the time to an abrogation of the Bank Charter.

Many important questions will be raised when the subject of the Bank Charter comes to be discussed in the approaching session of Parliament. Amongst these will probably be the inquiry how far a charter, granted in 1844, when the exports of British and Irish produce amounted to 52 millions sterling, and the tonnage of shipping entered and cleared at our ports was 10¼ million tons, is applicable to our commerce in 1856, when the exports have risen to 96¼ millions sterling, and the tonnage to 21½ million tons?

The cause of the decrease of gold at the Bank is, in part, the unfavourable state of the exchanges, or the excess of imports over the exports, which must be paid for in specie. But, independent of this, the requirements of the French government have compelled it to purchase bullion of the Bank of England at a heavy premium. The amount of gold and silver coined in France since 1848 is nearly 112 millions sterling, being respectively £88,351,000 in gold, and £23,631,000 in silver; whilst that coined in the United Kingdom is £52,438,000 sterling, or £50,378,000 in gold, and £2,060,000 sterling in silver.

We must not, however, conclude our statement without stating that the *immediate* cause of the financial crisis was the panic, and consequent extensive failures, in America, which stopped the remittances from that country, and produced a heavy pressure upon our banks. The letter-of-licence from Lord Palmerston to the Bank of England relieved the commerce of the country *for the time;* the object of Parliament must be to devise means to prevent, as far as possible, the recurrence of these crises, which cause so much distress in the commercial world.

WHO INVENTED THE STEAM PLOUGH?

Sir,—I have read with much interest in your journal for several weeks, "A Plain Farmer's View of the New Things in Agriculture;" and I am pleased to see, that, although he styles himself "A Plain Farmer," he is not a prejudiced one.

In your paper of November 16th he was pleased to notice Mr. Smith's and my own modes of steam culture; and it is with reference to his observations, and Mr. Smith's letter of this week, that I crave a place in your columns to correct an error into which they appear to have fallen, with respect to Mr. Smith being the inventor of the steam plough.

Your "Plain Farmer" says, "Mr. Smith shall next have my notice, as he has been indefatigable in the introduction of steam power to cultivation, *and also lays claim to being the originator of the modern improvements in steam ploughing.*" To which Mr. Smith replies, "I find it stated that I claim to be the originator of the windlasses and rope traction for ploughing by steam. I say Mr. Hannam made the first attempt, but failed; *and that it was I who first efficiently originated and applied them.*"

Now, Sir, in justice to myself, I beg to state, that three years at least before Mr. Smith entered into it I ploughed part of my farm with a five-horse engine; and as long ago as the *Lewes Cattle Show*, 1852, I took a model of a ploughing machine to that meeting, and showed it to Messrs. Clayton and Shuttleworth, asking them to carry it out, but they declined, and I have been obliged to manufacture and work it out myself. At that meeting I well remember Mr. Fowler (who made Mr. Smith's machine) was *draining* in a meadow adjoining the show-yard *with horses*, he not having as yet applied the steam engine to that purpose. In June, 1854, I took out a patent for a combined lever plough and cultivator, and in May, 1855 (previous to the Carlisle meeting), I patented my first mode of steam culture, viz., with one engine, to work both ways by means of a platform and pulleys at the opposite headland, the engine, machine, &c., to move forward *and keep opposite the work.*

On the same day I opened a discussion at the Central London Farmers' Club, "On the General Application of Steam-power to Agricultural Purposes;" and I mentioned the names of every person that I could ascertain had made any attempts at steam ploughing (Mr. Hannam amongst the rest); but Mr. Smith's name was not there, for the very reason, that, as yet, he had no hand in it.

All this I had done before Mr. Fowler contracted to make Mr. Smith's machine. The model, which I exhibited last year at the Smithfield Show, was made, that drawings might be taken from it; and if your readers and the public at large will refer to your paper of May 14th, 1855, or *Bell's Weekly Messenger* of the same date, they will find my predictions there stated, which are being more confirmed every day; and it will require no further argument than that discussion, and the dates that I have given above, to prove, amongst those who are carrying out the modern improvements in steam ploughing, "who was the inventor of the steam plough."

I have subsequently patented another mode of using two engines, *with machines attached, to do away with all friction of pulleys, and to require no more rope than the length of the field*, the same to move along the headlands, as before described, and which was exhibited at Salisbury. And also a method of making the common portable engines "*locomotive*," by means of a chain motion connecting the crank-shaft to the hind wheel; thus propelling themselves along. Your "Plain Farmer" will perhaps be pleased to know, that my two engines brought themselves and their respective machines home from Salisbury, a distance of forty miles, with the assistance of one horse to steer; carrying, in addition to the weight of the machine, 100 gallons of water and half a ton of coal, and only had assistance at two hills, which were very long and steep.

Your correspondent, who appears to me to have given a very fair and descriptive account of the several implements at work at Salisbury, says of my ploughs, "The ploughs are badly arranged." Now, I have no right to find fault with his decision, because their work was not such as I could have wished; but when I tell him that it was never tried till on that piece, and was the first I had made in that form being actually finished at Salisbury, and that being obliged, from want of power, to take off two ploughs on account of the impracticable position in which we were placed, *and consequently the line of draught being incorrect;* he will perhaps make some allowance for their performance on the hill, as on every occasion since they have made excellent work. The ex Mayor of Salisbury was much pleased with their work on his farm. Mr. Boydell has tried them behind his traction engine, and told me he never made such good work with a combined plough; and they have been tried in Staffordshire, making equally good work there. Your correspondent, who

is evidently well up in mechanics, will perhaps form a different opinion of my ploughs when I tell him that, *by their construction*, they are capable of being altered in five minutes from a four-furrow or six-furrow plough to a ridge plough, by simply taking off the first, third, and fifth plough-bodies, and substituting a large steel broadshare in their stead. The work is then performed as follows: The first beam, carrying a broadshare, cuts and breaks up the soil, but does not turn it; the second beam, a plough, cuts its own ground, and turns it on the top of the other; the others alternately acting the same, throwing the whole into ridges or rafters, and the whole of it being broken up, it lies admirably for exposure to the atmosphere and the frost. Several farmers in Staffordshire told me, on seeing it work, "they should like all their land done like it."

I ought to apologise, Mr. Editor, for the length of my letter; but I know that anything relating to steam culture finds a ready place in your columns. And as on a past occasion, when a long controversy as to "Who invented the Steam Plough?" took place in your journal, I took no part therein, feeling convinced that—having proposed and introduced the subject of "Steam Cultivation" at the London Farmers' Club, previous to either of the disputants taking any part in it, and the publicity that was given to that discussion through your paper and several others, besides the Journal of the Club—that the public would give me credit for being first in the matter. However, it appears that "A Plain Farmer" was not aware of the fact, and possibly many more like him; I therefore consider it a duty I owe to myself to put this matter straight, as I am not only the inventor of the hauling machine, but it will be found that, ultimately, when brought to perfection, *my system of moving ahead opposite the work* will be the best.

I remain, Mr. Editor, yours faithfully,

J. A. WILLIAMS.

Baydon, Wilts, Nov. 24, 1857.

THE PROPER POSITION OF THE LABOURING MAN.

Reflections arising out of the Rev. C. T. James's eloquent address and the afternoon discussion on labourers' education we have already offered to our readers, We shall now give a few more, which, on the contrary, were never likely to occur to anybody from a perusal of what passed at the Farmers' Club. Our working-classes, having no newspaper, edited, contributed to, and supported by themselves, speaking their views and stating their wants and wishes, read what we write for them, and have their case always pleaded by men of a class above them. A journal, therefore, like the *Mark-lane Express*, representing all the interests connected with agriculture, whether owning, occupying, or labouring, should not be frugal of its devotion to the cause of the workman, while giving due regard to the rights and duties of the landlord and tenant-farmer. The subject of improving the educational condition of the agricultural labourer was or should have been treated, on the above occasion, in its relation to the exigencies of the farmer. We would now extend the topic in a somewhat new direction, bearing upon the welfare of the labourer himself, and through him of the whole community.

It is certainly worth while to persist in urging upon sluggish and short-sighted farmers that their interests would be advanced by doing a little bit of philanthropy among their work-people; and there are many ignorant masters yet left, who cannot perceive any good in making their men more thoughtful as well as more handy than they now are. But our intelligent men of business admit all you can plead on behalf of more extended education (that is, of mental, moral, and bodily training), and deplore with you that the thing remains so scantily and insignificantly done. Shrewd and calculating, as well as right-minded and benevolent men, agree that it would be better for all classes if labourers could have higher wages, earned more at piece-work than by the day, and were paid perhaps partly in bread-corn or barley for home-brewing. If their homes were more decent and comfortable; if they universally had rood-pieces for potatoes, grain, and garden vegetables (not omitting floral beauties by cottage-doors and windows), and did they all possess, if not the poor-man's Elysian blessedness of a milk-giving cow agisted by the master, at any rate a sleek economizing pig or two in the manure-making sty. You may add also every variety of sick-club, coal-club, savings-banks, &c., for providence and mutual help, and crown the list with evening-classes for adults, and time and opportunity for good training for their families, with, perhaps, athletic games and rural festivals in which all classes may cheerily mingle.

Still further, every one whose views are worthy of respect acknowledge that farmers are greatly to blame for their remissness in many of these matters; that clergymen, and squires, and people of influence and power are accusable of great neglect in some points; and that landowners and proprietors are impeachable with reference to others. Then again, the good ladies, who, like improvised Sisters of Mercy, parcel out "their poor" into visiting districts, tell us that personal improvidence and recklessness in the men, and a want of ability for cooking, soup-making, and working-up of domestic odds-and-ends in the wives, mothers, and daughters, are sufficient to account for much of the labourers' poverty. Even beyond these, there is the teetotaller charging the brewers and publicans with being at the bottom of more than half the mischief and misery. It is a matter for general congratulation that we at last know and admit these things, and that we treat the labourers' case in a better spirit than we did. At an agricultural meeting, when the hard-handed, hard-headed fellows come up into the dining-hall to receive the golden honours for prize ploughing, and the careful old servant, housemaid, and the diligent scholar, or clever little needlewoman from the parish school, share in the distribution of rewards, the benevolent vicar or his indefatigable curate makes a fatherly address to this *élite* of the working-classes, fairly and good-humouredly adverting to the above-mentioned grievances—generally concluding, by-the-bye, with an earnest appeal against tobacco and the beer-shop, just as the health of the labourer is being drunk by their masters with "three times three." On greater occasions, too, our noble lords and right honourables, as well as plain agriculturists, in dilating upon the "operative" question, invariably enforce the principle that the men who slave for the community, for capitalists and gentry, have a right to receive education and assistance from the classes above them; and that it is the bounden duty of all, above the position of being drudges of society, to help their toiling brothers in proportion to the measure of their own affluence and

prosperity. Thus, it is not only the selfish principle (or want of "principle") within us that is appealed. Something more is set before us than the mere advantage to ourselves of having better-fed, better-housed, better-taught "lower orders;" of having fewer pestilential and feverous courts and back lanes to involve our wealthier mansions in their subtle poisoning, and having fewer temptations of want and ignorance and vice pressing the poor to rob and hate and attack the rich. Our sense of fairness and honour, our sympathy and generosity are appealed to, and we are constrained to declare whether or not it is fair and righteous that our fellow-citizens, who strain their sinews, waste their energies, and hazard their health and existence most, should eat of the plainest, and be comforted with the hardest. Or, that they should dwarf and dwindle on dry bread, while the more fortunate and idle partake of the best of palatable luxuries. Our own sense of justness and fitness and propriety tells us that a condition of society in which the workman obtains the least part of Nature's bounties, and does not find that he is "worthy of his hire," cannot be in accordance with the perfect and normal government of the universe by a Providence of equity and mercy. Let us even confess that there is something wrong in our present social and economic arrangements for distributing the profits of the products of labour; doubtless permitted by the Ruler of the nations for a wise and righteous end, but which shall be adjusted and compensated for in that millennial age to which the world looks ever forward.

Now, no one will suppose that we are going to open up the theories and fallacies of "socialism," or to quarrel with our existing national institutions. All we want to impress upon the true labourers' friends is, that remedial and alleviating measures, good and necessary as they are, can only be of temporary effect, and should not be urged and agitated as if they constituted a complete solution of that perplexing problem, the "labour question." True, there is plenty of work for us, at present, in getting such measures as cottage-building, piece-work, allotments, and schooling, admitted and actively set-about in the right quarters; so that present distress may be allayed, present abuses removed, and a brighter prospect unfolded to the sons of toil. But so long as the framework, customs, and regulations of society permit and establish an imperfect, unequal, and therefore dangerous appropriation by different classes of the nation's industrial earnings, all such measures will fail to reconcile the working-classes to their position, or make them as happy and contented as they should be. Anyone who considers the general condition of society at the present day, must see that only by a vast change in the character, sympathies, and customs of the various classes of the community, can there be a period inaugurated in which men shall always be able to command their reasonable share of the national store of food and comforts, as well as of leisure for mental culture. But in effecting this alteration, there is no necessity for any sudden or violent organic change in our social or political state. Neither need we wait until the Christian rule of "doing unto others as we would they should do unto us" shall be the inspiring motive in every man's heart. By means of sentiment and habit slowly growing up among us, and as a step toward the attainment of the prophesied world of honest men, we believe it will be possible for all classes mutually to agree as to their respective functions, duties, and just scale of remuneration; so that inequality and oppression shall be individual, and no longer inflicted by one entire class upon another. And this time will arrive only when men are qualified for the work allotted to them, and when that work is always such as reasoning, reflecting human beings may be satisfied to spend their life in, and earn their living by. This, then, is the point we would enforce—that the only permanent and safe condition of the working-classes is when their position is fairly and honestly *as good in its way* as that of other classes. When no man who is too weak to rise out of this situation in life need be ashamed of or disgusted with it.

There are two ways of endeavouring to bring this about—one consisting in measures for securing the labourer better payment for his toil, either in wages, household comforts, or educational privileges; and the other seeking to improve and elevate the nature of *the work itself*, rescuing the workman from occupations purely animal or mechanical, and employing him in such as engage the faculties of his mind.

We continually hear suggestions for aiding the former, but very seldom for advancing the latter method.

One of the saddest facts connected with the condition of many of our working-classes is, that a worse than the primeval curse has fallen upon them. "In the sweat of thy brow shalt thou eat bread," was the judgment pronounced against Adam and his posterity. Alas! how many of our labourers have come to suffer this penalty in its narrowed literal meaning—eating "bread" and bread only, often not a sufficiency of that, in recompence for "the sweat of their brow!" But with the progress of machinery, the increase of population, and an enormous consumptive demand for cheap articles of prepared food, manufactured apparel, furniture, and workmanship of art and ornament, there has gradually crept upon the "operatives" a worse form of laborious occupation than is included in this figure of the perspiring brow—unless, indeed, the expression be not only metaphorical, but symbolical. This may be taken to indicate that fearful, horrible, and cruel wasting of the souls of men in forms of labour engaging only their animal power, and calling for no exertion of their minds, which has become a necessity of actual existence to tens of thousands of pale men rightly named "mechanics;" as also to others proudly classing themselves in a higher grade of occupation. Our "mills" and "works" abound with men and women, young and old, who would rejoice might they but vary their bodily labours and revive their mental languor in work that had *thought* in it—in processes but the least elevated above the monotony of recurrence, repetition, and relentless copying. The joiner has scope for contrivance and invention in laying-out a window-sash of a new pattern, or a staircase of novel combination of curve and pitch; but look at that workman in the tool-factory, who does nothing for days, months, years, but cut out with a turn-saw rough wood handles of a shape marked out for him, never finishing or varying one. Or look, again, at that old man bending over a saw, and tap-tapping its teeth with its ceaseless hammer to give them the right "set." The accurate touch of his blow is marvellous, but for years and years his daily life has been consumed in as unintelligent a task as that of the horse pacing round his infinite mill-walk.

Bodily toil, even excessive at times, is healthful and invigorating both to the physical and intellectual faculties. But to labour your whole day, and every day for a life-time, at work which has no progress or diversity in it, no space for design or the exercising of the gifts of a man's soul ever so humbly upon it—this is true slavery. In extorting such protracted changeless labour of body, or unrelaxed attention, to details admitting of no improvement by the thought of the workman, we are making not only a slave, but a machine of our brother—causing him not merely to yield

us "the service of his body" but to relinquish for our benefit the right and opportunity of exercising his mind. We are using his body and soul in lieu of machinery of brass and iron. Not that we blame capitalists, however, for manufacturing and consuming, or accuse the upper classes of living by such repression and degradation of the lower. By no means; for we are all in fault. And the factory-girls spend years in tying threads, in order that the poor housewife elsewhere may procure cheap calico; and the lad grows up to manhood in the din of the railworks, feeding strips of metal into the cutting engine, in order that we may save in building and constructing. Machinery has wonderfully extended knowledge and a high order of skill among workmen. Still at the same time it has made immense numbers of human beings into mere machines; and we believe that one of the best means of inaugurating a happier condition of the labouring-classes, is to introduce wood and metal wherever it can be economically made to take the place of human nerves and muscles and a low order of mental attention, confining manual labour to operations requiring thought, and exercising beneficial effects on the character of the workman. One of the finest pieces of education is to instruct a youth in the use, and entrust him with the care, of a machine or process needing the energy of his mind; and one of the worst kinds of intellectual degradation is to bind him ten or twelve hours a day to labour, for which the "unthinking horse" or other dumb beast might be equally fitted, had it hands instead of hoofs. What a difference in ability and independence of thought between the turner who holds the tool to the lathe, or the potter who shapes the vase upon the wheel, and their men who merely actuate the crank! What a distance of inferiority between the labourer that carries bricks to the scaffolding, and him that lays them in lintels or "string-courses" of his own designing!

While many have pitied poor Hodge, or rather the smart intelligent ploughman and carter that he is rapidly becoming, we do not know that anyone ever discovered the superiority of Hodge's kind of work over many tasks performed by the quick-fingered "division-of-labour" factory-folk. But think of the variety of his toils—of his judgment in guiding a team, or feeding a bullock—in straightening a furrow or paring a sheep's foot—in managing a drill, or sloping the banks and levelling the bottom of a ditch! Is there not selection and calculation in the plashing of a hedge; and taste, as well as tact and skill, in the building of an elegant and noble rick? True, there is still the old toil of filling dung-cart, for which strong-armed and weak-headed men are proverbially said to be fitted. But the progress of agricultural mechanics is gradually relieving the labourer of his more excessively mechanical toils. He is delivered from the long winter discipline of the flail; relieved of shaking-out grass and raking it up again as hay. He has been partially freed from the hoe; the steam engine, in large farmsteads, cuts, grinds, and crushes for him, leaving him to study the wants and comforts of the animals under his charge. The reaping machine has well-nigh saved him from the racking scythe and arduous sickle; the steam plough will soon make tillage-labour his pleasing occupation instead of his burden. There might also be a satisfactory comparison between the amount of happiness and mental satisfaction which Hodge finds in the nature and objects, and in watching the successful issue of his toil—the beasts turned-out fat for market, the crop prospering under his toil and attention, and so on, against the mere knowledge of having knocked-off so many pens or buttons per day, and seen them packed in boxes, never more to be heard of.

Some readers may fail to see at once how the elevation of the nature of his employment is to accomplish much in benefiting the labourer's condition. But just consider that some masters, as well as men, hold sentiments on this matter, and act in a way which may be stigmatised, without harshness or extravagance, as a species of brutality. They care only to keep their men at hard work, no matter at all what the nature of the work may be, provided it answers their purpose of profit—careless that human minds should be smothered in mere bestial occupations, with the natural result of debasing both the slaves and their task-masters. Such employers never consider *what sorts of labour are good for men*, and would have men and women dragging ploughs and harrows, if it were only legal, customary, and would pay.

But we ought not to reckon our labourers as so many "hands" merely, as the statisticians do. We are not to calculate the water-power, wind-power, steam-power, horse-power, and *manual-power* on an estate, as all alike in value, according to the number of pounds avoirdupois it can raise one foot per minute. We are blaspheming the work of God to do so—who "made man in His own image." Rather let us say, We have so many minds on our estate, each capable of more or less exercise in invention and study; and the aim should be to produce the highest result of yield and profit from the land, with the least harm and greatest improvement to the mental and moral powers of the workmen.

Again, reflect that if the masses of our population (who have the heaviest of the national work to do) are ever to be thinking, well-cultured men, and everybody must wish they were so, for the sake of humanity, morality, and religion, *they must have work that they can take pleasure in*. If labour is to continue to be so extensively only a mechanical slavery, the further you extend education and power for thought, the more dissatisfied will labourers be with that drudgery; and all the wisdom and power of the rich and titled will not hinder them from rebelling against it. Men have no right to be made to toil in that which they abhor, and which holds down their mental energies, if there be any means for making machinery perform it instead. And there are many cases in which, if mechanism cannot be economically applied in such work, the product can be dispensed with. We honour those who preach the dignity of labour, and strive to introduce whatever means may avail to make the workman's toil more pleasant to him.

Let our readers meditate on this subject. Let them consider that if "education," when left only to earliest youth, to evenings and spare hours, yet brings happy results, how much more may be done by altering and exalting the character of such occupations as absorb all a man's day in what is strictly and rigidly machine-like and material! We have alluded to the introduction of improved farm-implements as having in many ways lightened the pressure of the labourer's work; but there are other measures required—such as the relieving of boys and girls, and also women, from the painfully demoralizing system of field gang-work; the substitution of contract-work for much that is now unnecessarily done by the day, and other methods of giving the labourer a direct personal interest, and therefore of pleasure, in the task he is performing. We only urge a greater attention to the principle of employing men as much as possible in suitable operations, affording scope for the greatest exercise of what thinking faculty they may possess—leaving practical suggestions and applications for business-people to discover in the course of their daily arrangements and pursuits.

THE EDUCATION OF THE LABOURING CLASSES—CONSIDERED AS A NATIONAL QUESTION.

The education of the poor has ever been a stumbling-block, and so it must continue, so long as sectarian differences continue to exist, and to counteract the efforts of each other. An exemplification of this took place at the last discussion of the London Central Farmers' Club, where the different speakers took entirely different views of the question; while the testimony of what had taken place in their localities exhibited how badly the present plan worked, and the necessity of a general revision of the whole system. The Rev. Mr. James appears to have imbibed the same opinions that pertain to his class, that it is the bounden duty of the upper classes to provide education for the poor. As a Christian duty, it undoubtedly is so; but at the same time we must admit that it is the first duty of parents to provide education for their children, and when unable from poverty, it then becomes the duty of the state to supply it. It is to the wellbeing of a civilized community, that all its members should be educated and trained in their religious and moral duties, as well as provided with the means whereby afterwards to obtain a subsistence. So that the present system, as supported by voluntary subscriptions, which always press heavily upon the charitable and well-disposed portion of the community, should be equalized, and borne by the property of the country, and be paid through the same channel as other national charges. Until this system is adopted education never can become general. We cannot admit that knowledge is power, without at the same time admitting that knowledge is wealth—therefore the educating a child is in fact conferring upon it the benefit that it would derive were it given the sum of money considered as the equivalent.

The middle classes of this kingdom are sufficiently aware of the importance of education as to induce them to bestow it upon their children sufficiently to enable them to enter into the pursuits of after life, similar to their own. It is one of the most expensive charges that they have to contend with, as it very frequently happens to persons of slender means, averaging from £100 to £200 per annum, that the education of their children, even when carried out with economy, amounts to one-third of their entire incomes. In times of pressure, such have fallen upon the farmer, the amount of education conferred on their children has been totally inadequate to their requirements, and far below that frequently bestowed upon the children of their labourers, in such parishes as have schools endowed, or supported by the donations of well-disposed persons.

We maintain, therefore, that it is the state that is bound to provide education for the poor—not only to insure it—but also to compel all persons having property to contribute in fair proportion to their means, whether inclined or not, to promote so desirable a result. As a state necessity, and still further to ensure it, parents ought to be assisted, to enable their children to be educated until they attain the age of twelve years at least, or until they are enabled to read and write sufficiently well.

We are of opinion that it is unnecessary to teach the children of the poor anything beyond reading, writing, and simple arithmetic, accompanied with sound moral inculcation and religious teaching, such as the state is bound to provide; beyond this, it is the duty of the parent to provide, as the means of furthering the progress of his children through life; neither is it necessary, as it cannot be expected that all men and women should be equally endowed with mental ability—the different grades of society do not require it, neither would it produce what Mr. James so strongly contends for—skilled artizans and labourers. That department of education does not pertain to the schoolmaster, but devolves upon the parent to complete, either by his own tuition, or that of others appointed by him to the task.

In rural districts the necessity or carelessness of parents is the main obstacle to the education of their children. We know that the utmost difficulty exists in procuring scholars for the schools, and even when procured the irregularity that prevails prevents the education of the child proceeding steadily, or continuing long enough to become of any material advantage. The ideas that prevail among the dissenting classes of the poor too frequently operate to their own injury, especially if the school happens to be an endowed one, or in any way under the control of a clergyman. On the other hand, the strict discipline enforced by the latter in the teaching of children has the effect of driving away many from the school that would in its absence have been too glad to have attended.

Such is the difference in the natural endowment of the human mind, that education becomes only the stepping-stone by which men become advanced—the most skilled artizans are those who frequently have been the least educated—the same also holds good with our agricultural labourers; and so long as the one continues an artizan and the other a labourer, education simply considered would not have produced a better workman. Not that we advocate the opinion of some masters that the "weak in the head and strong in the arm make the best labourers," but we contend that skill and tact are natural abilities that become advanced by practice, rather than by education. But if we look more deeply into the question, we believe that education by teaching a man his duty, enables him the better afterwards to fulfil it; and if the education of the school is supported by the example and teaching of the parent the greatest benefit must inevitably follow.

The greatest obstacle to morality with the labouring youth arises after they have quitted school, and before they become settled in life. So soon as they can earn sufficient to emancipate themselves from their parents, an era which usually commences at the age of fifteen, they become their own masters, and without any control from their parents, seek at the alehouse, that comfort which in most instances could not be found at home—a comfortable fireside and "jolly companions." During the interval betwixt that period and manhood, the good instruction bestowed upon them previously becomes too frequently lost.

The advantage derived by evening schools has been insisted upon, but this would be made available to a large proportion of the labouring youth; during the winter months only, could any attendance at all be obtained, and even then many hours would require to be filled up beyond those actually spent here. In all populous villages the school-

room might be converted, at other times, into a reading-room, and at the trifling expense at which books can now be procured of an amusing and instructive character, the experiment is well worthy the attention of the benevolent, and would probably, in proportion to the outlay, be one of the cheapest modes of supplying the wants of the labouring classes.

The experience produced by our union schools is not very satisfactory, the children are instructed in the elements of learning but are perfectly helpless, as Mr. James expressed, of the best manner of using their arms and legs. This arises in a great measure from most of our unions not having sufficient land upon which to train them in such employment as they may be called upon in after-life to perform.

In conclusion, we can only state, that although insuperable difficulties appear to invest the question, we believe that they are more imaginary than real; and if the task of laying down a system of national education was only set about in earnest, and with a desire to prevent our prejudices operating so as to overcome our reason, we should very soon become convinced that it was no very difficult task, and feel surprised indeed, that it could have been so long delayed in execution.

THE STEAM-ENGINE AND OTHER MACHINERY TRIALS FOR THE CHESTER MEETING—SUGGESTIONS.

I have been much interested, as also greatly amused, by reading the various observations and suggestions made by the respective manufacturers of steam-engines, thrashing-machines, mills, chaff-cutters, &c., &c., relative to the triennial trial of these classes of machines, as already arranged to be tested at the ensuing meeting of the Royal Agricultural Society, to be held at Chester. How they are to be met I cannot conceive; and yet very many of them are truly valuable. I will try and combine the sense of them, and perhaps indulge in a remark or two upon them in passing.

Triennial Trials. — The first observation I shall notice is that of triennial tests of merit, by which a larger number of implements and machines may have a chance of a more extended and a more efficient trial. I find this plan is generally approved of in its essence, but grave objections are made to its full efficiency. These objections will certainly lie. It is not right that every trial should invariably be made at the time of the meeting, whether circumstances are favourable or not. Ploughing, for instance, should only be done when the soil and season are suitable. Reaping should only be performed upon ripe crops.

Medals or Diplomas —The next thing I shall notice is the suggestion to set aside money-prizes as a token of merit, and substitute medals or diplomas. I don't like this. A money-prize is undoubtedly no great object to a large and wealthy firm: a medal is always in view; but how many poor, hard-working men have come out as clever inventors and mechanists, to whom the chance of a money-prize has been a great incentive, and, when obtained, a great help! Besides, Old John Bull looks to the money: his pride does not consist in a medal encased in morocco: he loves to hear the chink; on hearing which he *will* work.

Trial of Steam Engines. — The trial of steam-engines I will next notice. It is one of high importance' and is the most valuable investigation to be made at Chester. It deserves the utmost care in perfecting all the arrangements for a satisfactory and conclusive trial. For this purpose the society puts forth certain conditions to be observed by competitors. This is right enough, to a certain extent: it is quite right to cause exhibitors to particularise and define the amount of horse-power, the thickness and quality of the boiler-plates, the diameter of the cylinder, the length of stroke of the piston, the number of revolutions of the crank-shaft, the diameter and weight of the fly-wheel, and also of the driving-pulley and its width and speed, together with a sectional plan of the boiler, showing the action of the fire upon the flues, and stating the area of fire-surface, and the clear water-space between the tubes; this is perfectly correct, but beyond this I don't see that more ought to be required of them; all other matters should be left to their discretion. The trials, I presume, are intended to ascertain and prove the value of the engine under trial, with all its merits or demerits, and with all its improvements and additions, be they good or bad, as exhibited before the judges by the sanguine exhibitors. The Society should be provided with every necessary scientific apparatus to test the *power*, to prove the quantity of *water* used, and the amount of *evaporation*. Indeed, every aid must be offered by the Society to insure a perfect trial; but every manufacturer should be left perfectly free to take his own course in the construction and manufacture of his engine. It is for the judges to say if he has succeeded in producing the best in his class. I take it as a necessary adjunct that exhibitors shall be required to state of what and how such parts of their engine is constructed, which does not appear to the view of the judges; beyond that, the judges should detect any defect, or note any progression, and the Society should always have the power to take to pieces any engine for examination, if required by the judges. In arranging for the trial of these engines, the coal should be of the best bituminous quality, equally broken and clear from rubbish or dust, all accurately weighed from the same heap. The trials should take place under a suitable shed, containing the engine and dynamometer.

Thrashing Machines.—The grain to be thrashed should all be from the same stack, and the sheaves should be weighed as well as counted. The trial should take place also under a suitable shed, and should extend to fifteen or thirty minutes each, during which time every circumstance in the working and dressing must be carefully noted by the engineers and judges, and the produce weighed as well as measured, thus making a double test —the weight and quantity—the greater weight proving the better dressing.

Mills of all kinds.—At the Lincoln Meeting a standard sample was crushed or ground, and time given for exhibitors to adjust their mills to this standard, and from this point the adjudications were made. At Carlisle, the best samples produced with the least waste of power was the chief guide. This was carefully tested. I recollect seeing a mill there dancing about under trial most amusingly, owing to ill-regulated power. This is a great point for consideration. They should have thirty minutes each for a trial, and time for adjustment for different qualities of flour and meal.

Chaff Cutters.—These are very various in make and adaptation, and qualified for cutting different lengths. In trial all should be set to accomplish the same kind of work, and to cut the same length of chaff; otherwise no real test can be given. It is suggested that some foreign

material be used along with the straw, to show the length, *i.e.*, a piece of soft wood, or slip of pine. This would be serviceable. The break or dynamometer will prove the power absorbed, and the measure the quantity.

Dressing Machines.—These, if possible, are more varied in pattern and uses than chaff-engines. These machines should be made capable of performing all kinds of dressing, from the foulest corn to fine seeds. The dynamometer readily shows the power used. The judges decide the work.

Adjudication by Points.—The last thing I shall notice in this short paper is the novel mode suggested by several manufacturers for arriving at a satisfactory adjudication, viz., by the representation of a given number of points. Take Messrs. Ransomes and Sims' suggestion as to points.

		Points.	
	1. Durability,	to count 20	
	2. Simplicity,	„ 20	
	3. Material and workmanship,	„ 20	100 points.
Duty done on	4. Consumption of coal,	„ 20	
	5. Portability,	„ 10	
	6. Price per horse-power,	„ 10	

What work for judges, even with this defined for their guidance! What is to rule them? If one machine is somewhat better finished than another, is it to count 20 points; and the other, of which the judges have a wavering opinion as to what is best, to count nothing? Again, the latter may be the most simple in construction by some slight difference, then it counts 20; the first nothing, and so on. Then what are the tests of durability but material and workmanship? and so both get the 20 points. Then again, what is portability: a light frame on light carriages? That would never do; yet it gets 10 points. Again, price per horse-power? Why it seems the lowest-priced or the least costly make would win here, when generally the best-made engines are the most costly; yet it has the 10 points. Consumption of coal has something definite. Here a test can be applied; so we will give the 10 or 20 points as these gentlemen suggest. In many machines similar results may be obtained. Thrashing-machines, dressing-machines, chaff-engines and mills might possibly be so determined, because they each have many "duties" to perform, and a given number of points might indicate grades of merit, but it would be very indefinite. If points are to be adopted as an index of merit, the division must be free and open; it must be left to the discretion of the judges to place such a number of points to the *merit* as it is entitled to, and not have it defined for them. What bones of contention! Points—defined points—will never do; they would frequently bring inferior machines and implements first. I have often seen splendidly-made machinery which was of no practical use. The mill I have named was precisely of that class: it appeared of beautiful manufacture, but the *break* proved it worthless. I see no true way of solving these difficulties better than to trust to the free unprejudiced judgment of really good practical men, aided, as they now are, by so many true mechanical and scientific powers. The power used can be detected to the greatest nicety by the dynamometer. The quantity and evaporation of water can be ascertained by the water-meter. The coals can readily be weighed, and other matters can be proved, so that, in fact, the judge of implements and machinery is vastly aided in coming to a decision; and he has, for the most part, mainly to exercise his judgment as to the quality of the work performed.

THE BIRMINGHAM AND MIDLAND COUNTIES FAT CATTLE AND POULTRY SHOW.

As an agricultural exhibition, that at Birmingham, even as a commercial speculation, should be eminently successful. It enjoys, in a word, just double the attractions of any other such gathering. Quite as many, or more, people go to see the Poultry than there do to see the Stock. Whereas at other meetings the cocks and hens are of little consideration, and half the visitors most likely never look at them. Birmingham, from the very first, has had a long lead in this respect that has never been approached. We have had Poultry Shows in Baker-street and at the Crystal Palace. The Royal Agricultural Society itself has ventured on a few mild accessories of the kind. Even exhibitors, however, think comparatively very little of them; while on the other hand, taking the prize for the best pen at Bingley Hall is something equivalent to winning the Derby, or the Gold Medal at Smithfield. Still, in the very face of this, with everything as well done as it could be, the funds of the Midland Counties Show have not been in too flourishing a condition. The fact is, or was, the Society, like many an individual ere now, had over-housed itself. Bingley-hall is, by this, proverbially well known as the best show-yard in the three kingdoms; but then, unfortunately, it is nothing more. For fifty-one weeks in the year the Hall is little better than a dead letter. The Bounding Brothers may occasionally, for a day or so, display their athletic forms, or Madame Robinsino pirouette from the back of a piebald steed. But beyond this the Society has so far had little to aid them in paying so large a rent; and consequently, although they have done everything to ensure the attendance of visitors, they have still had serious difficulties to contend with. There may be something of a lesson or a moral in this. There is scarcely a spectator or an exhibitor enters Bingley-hall but says at once, "Ah! we ought to have such a place as this for our London shows!" We were told as much, over and over again, during this past week. But yet a little reflection, ere we proceed to such a step, may be not altogether unadvisable. Whose money is to build? What shall we do with our hall when we have no fat cattle to put in it? And would it be sure to be a safe speculation in other ways? The Birmingham Show has, we repeat, the best place for its meeting of any we ever entered; and the one great drag on the Society is this self-same capital place!

It must not be supposed, however, that "the Midland Counties" is in a desponding or declining condition. The reverse of this is the case. The Council last year boldly faced their rent-difficulty, and, by a little exertion amongst themselves, have, we believe, nearly conquered it. As for the Meeting, it is now better supported in every way than it hitherto has been. The Society gives more money in premiums, the exhibitors enter in greater numbers, and the character of the Meeting is manifestly improving. The Poultry Show no longer depends on monstrosities or "rages," but is really what it should be—a collection of useful

birds. As a gathering of stock, again, the weak places have been gradually filled up, more particularly within the last year or two; since care has been taken to avoid any further collision with the Smithfield week. The Birmingham Meeting has still its own especial features in full force—its Herefords and Long-horn cattle, Shropshire sheep, and Tamworth pigs. But it has, with these, other sorts as well represented; and is, indeed, a Midland Counties Show no longer. You may look to the best of their breeds here almost as certainly as you would in London; and we shall be by no means surprised to see the Gold Medal beasts of Bingley Hall equally distinguished this week in Baker-street.

It will be rather strange if they are not. Mr. Shaw's Hereford ox and Colonel Towneley's shorthorn cow are two as fine specimens of their several breeds as were almost ever seen. Were it not for a little dip in the back of the ox, or had the cow only a rather better head, either might have been passed as perfect. Mr. Shaw's beast is a magnificent animal, of immense length and depth, with all the good points of the Hereford beautifully developed. There was no mistake about his claim to the Gold Medal; while it is a pleasure to see this carried off by a new man. Beyond the local shows of his neighbourhood, or as the exhibitor of a few good sheep at this show, Mr. Shaw's name is not a familiar one in the catalogue; and the only previous occasion, we hear, on which this ox had been shown, was at Rugby within the last fortnight, where of course he was also placed the first of his class. Colonel Towneley, the owner of the Gold Medal cow, is far more generally known as a successful exhibitor, and this cow herself has some fame in our show-yards. She is, moreover, not only one of the best looking, but one of the best bred of her kind. As recently as the end of last July "Victoria"—for so is she called — was declared to be the best Shorthorn cow at the Salisbury Great National Meeting. She was also the best of her year at Chelmsford in 1856. She is of capital proportions, roomy, and of excellent quality. She is just four years old, and has had one calf. The first prize breeding boar at Salisbury was the first-prize fat pig at Birmingham. So that, in point of fact, the breeding stock show of the Royal Agricultural Society is becoming a mere "feeder" to our fat cattle shows of a few weeks on. You are told to admire a magnificent beast or a good pig, and think to yourself how much such animals will do, now their merits are known, to improve our breeds. Most impotent conclusion! By Christmas-day they will be selling as beef and bacon.

There is another bad habit creeping into these meetings, that may be very appropriately noticed here. For the last few seasons the entry of Devon cattle has been gradually getting better and better at the Midland Counties anniversaries. This year the improvement is very marked. Lord Leicester takes the two prizes for the oxen or steers, with a pair of his own breeding. The first prize is one of the most evenly-fed oxen ever seen, and both are admirable specimens of that *multum in parvo* capability (of packing a great deal of meat in a small compass) that so signally distinguishes the Devons. Mr. Heath supports his Lordship with another brace of very beautiful beasts, both highly commended; and then we come to a third, also highly commended. This turns out to be nothing more or less than the Gold Medal Smithfield Club ox of last Christmas, then the property of Mr. Heath, but now standing in the name of Mr. Passmore. So that this ox was fed for the meeting in December, then kept on for the Poissy Show in the spring, and now made up again for another Christmas! He is getting on for six years old, and has not improved in any way since last year. This is hardly an illustration of early maturity, but is more like keeping a plater to run on, as long as his legs will carry him. We did not notice that those of Mr. Potter's beast were failing him, so that most likely we shall meet him about for some seasons to come. By all means let young animals be kept on to show how they will develop; but really, re-feeding or fattening an animal over four or five years old sounds like an absurdity. The first prize Hereford steer, for example, a wonderful animal for his age, of great width and weight, should be kept on another year, as most probably he will be. By that time he promises to be quite as good a beast as that of Mr. Shaw.

The show of Herefords was right through, cows, heifers, and all, a very capital one. We seldom remember a better class of cows, and the first and second prizes, of very even merit, had all the fine points of the sort. When well-fed there is perhaps no so telling a looking beast as the Hereford. The very way in which they are marked gives them a favourable appearance. By-the-bye, is there such a thing as a *white* Hereford? There was one entered and shown as such, though we rather question whether, if he "claimed kindred here," he would "have that claim allowed."

The Society is, notwithstanding, very strict in its regulations on matters of purity. Some very good-looking Shorthorns, including the prize one of Lord Lichfield, had to be entered in the extra classes from the want of pedigree, or of some such proof of their descent. On the other hand, there were some leggy, patchy beasts in the classes proper, that in these times we should have scarcely thought worth sending. In fact, the Shorthorn oxen and steers were all below the mark; while the cows were as good as the others were bad. Of seventeen Shorthorn cows and heifers exhibited, sixteen had either premiums or commendations. The judges, to be sure, were very liberal in this respect, and commended occasionally where they had better, perhaps, have not left their sign. But this was not the case with the Shorthorn cows, all of which fairly merited the compliment. Indeed the cows were all good, the Devons being another excellent class, with the Prince Consort's heifer as the pick from amongst them. She is a most beautiful creature, and does equal credit to the Prince as her feeder, and to Mr. Hole, of Dunster, as her breeder.

The excellencies of the Longhorn are certainly not seen in a show-yard. The Highlanders and Welsh cattle—both famous eating—were short in entries, and no-ways so good as we have seen them; while the most interesting cross was one exhibited by his Grace the Duke of Beaufort, who seems fond of experiments. This was between a West Highlander and a Devon, in which some of the points of either were well preserved. It is satisfactory to see that the Longhorn is being fast crossed into a Shorthorn.

The sheep show at Birmingham is seldom, at least in point of numbers, a very great one. Two or three of our favourite sorts are generally in the hands of two or three as well-known breeders. As, for instance, Mr. Foljambe and Lord Exeter enter from their Leicester flocks, and Lord Walsingham from his Southdowns. This season Mr. Foljambe takes every premium awarded for the Longwools, and his Lordship is nearly as successful as he was last Christmas with his Downs. But within a very few years Lord Walsingham has made extraordinary progress with his sheep, and they have now quite a character of their own—beautiful heads, straight backs, and great width behind the shoulder. So generally good, indeed, are they, that it was again difficult to pick out the best of the lot, many going to a merely commended pen for him. The Cotswolds do not abound here, but their cross with

the Southdown was seen to great advantage. People as yet have scarcely become familiar with its new title, but "the Oxfordshire Down" is a most useful-looking sheep, for almost anything you require of him. He has here, however, some especially formidable opposition to contend with. The sort of all others entered in anything like numerical force is the Shropshire Down, a variety coming fast into fashion, and that some think will soon be at the top of the tree. Still even the Shropshire Down does not stand quite on his own merits. The purest bred sheep of this kind in the yard were perhaps those of Lord Aylesford; and the best, once more, those of Mr. Smith of Sutton Maddock. The latter have a taste of the Southdown in them, imported from such men as Jonas Webb, Sainsbury, and Lugar. Both the first prize pens of Shropshire, those of Mr. Foster, as well Mr. Smith's, were of this improved character. Originally they claim to be a distinct breed of sheep; but now, like their cotemporaries, the Hampshire and Oxfordshire, they have to go to the thoroughbred Down as a refining medium.

The Midland Counties show of pigs is always a great one. The town and neighbourhood has a strong taste for the unclean animal; while such men as Messrs. Watson, Mangles, and Wiley generally give their support. As we have already intimated, the first-prize fat pig was Mr. Mangles' "Bendigo," the prize boar at Salisbury, and a most successful cross between the Yorkshire and Cumberland breeds. His portrait appears in the *Farmer's Magazine* for this month: not, of course, as a fat pig at Birmingham, but as a breeding one at Salisbury. The prize list will show that most of our best varieties were well represented. The run, however, was upon the Berkshires, of which Mr. Smith, of Henley-in-Arden, brought a pen of five unusually good young pigs. Two or three rather cautiously-worded certificates were handed in by the referees as to the ages of some of the pigs exhibited; although it seems scarcely possible that gentlemen of character should commit themselves in this wise.

An excellent show of roots admirably arranged, and as usual, a most attractive one of poultry, complete the chronicle. As we cannot find room for the awards in this latter department, we will allow, as far as is possible, the judges to tell their own story. In addition, then, to infinite commendations, they declared the golden pencilled Hamburgs, to be "a very good class"—the golden spangled Hamburgh to be "an extraordinarily good class"—the silver pencilled Hamburghs "a very good class"—and the same of the silver spangled. The Polish they passed without comment, but the Spanish were "excellent"—"meritorious and useful" and "unusually good." The coloured Dorkings "marvellous!" and the whites "improving." They deliberately pronounced the buff Cochins to be "*beautiful*" and the browns "excellent;" some of the game were also "excellent," and to the bantams they gave one "general high commendation." Of the game bantams they "could not speak too highly." The geese and Rouen ducks furnished "good classes," and the turkeys an "excellent one." We can only add to this, that there were pigeons of such fanciful tonsure and fashion as to utterly defy description. We can only hope such exquisites are never intended for pies. But still a layer of Mr. Towneley's famous cow, with two or three couples of prize Jacobins or Archangels over it, would be "a dainty dish to set before a queen."

We have often ere now had to speak to the good management displayed in Bingley Hall. If it were possible to improve on this, it has been done. Even on the best of the shilling days there was nothing like a crowd or a crush. Rarely was there a difficulty to see anything you wanted to—having when just as Mr. Davis had pitched his easel opposite a prize animal; or for the moment, as some right reverend enthusiast held forth on the many beauties of a bird he was anxious to buy—or to sell.

PRIZE LIST.

FAT CATTLE.

JUDGES:—Mr. Samuel Bloxsidge, Warwick.
Mr. John Tanner Davy, Ashtown House, South Molton, Devon.
Mr. Charles Stokes, Kingston, Kegworth, Derby.

HEREFORDS.

CLASS I.—OXEN OR STEERS.

First prize £10, with extra prize of £20 as best Hereford, and GOLD MEDAL as best of all the oxen, Mr. John Shaw, Hunshury Hill, Northampton. Silver medal to breeder, Mr. Richard Shirley, Bawcott, Munslow, Shropshire.

Second, £5, Mr. William Heath, Ludham Hall, Norwich, Norfolk.

The Class generally commended.

CLASS II.—STEERS.

First prize, £10, and silver medal as breeder, Mr. John Naylor, Leighton Hall, Welshpool.

Second, £5, Mr. William Child, Wigmore Grange, Leintwardine, Herefordshire.

Commended, His Royal Highness the Prince Consort, Windsor Castle; the Earl of Aylesford, Packington, for two steers; and Mr. Joseph Phillips, Ardington, Wantage, Berkshire.

CLASS III.—COWS.

First prize, £10, and silver medal as breeder, Mr. Philip Turner, The Leen, Pembridge, Herefordshire (had three calves).

Second, £5, Mr. Edward Thomas, Colebatch, Bishop's Castle, Shropshire (had two calves).

The Class generally commended.

CLASS IV.—HEIFERS.

First prize £10, and silver medal to breeder, Mr. Henry Higgins, Woolaston Grange, near Lydney, Gloucestershire.

Second, £5, Mr. Samuel Walker Urwick, Leinthall Starks, Ludlow.

SHORTHORNS.

CLASS V.—OXEN OR STEERS.

First prize £10, and silver medal as breeder, Mr. William Eyton, Gonsal, Shrewsbury.

Second, £5, Mr. John Robinson, Leckby Palace, Topcliffe, Thirsk.

Commended, Mr. William Winterton, Wolvey Villa, Nuneaton; and Mr. Henry Roberts, Paxford, Blockley, Worcestershire.

CLASS VI.—STEERS.

First prize £10, and silver medal as breeder, Mr. Richard Stratton, Broad Hinton, Swindon.

Second, £5, Earl Spencer, Althorp, Northamptonshire.

CLASS VII.—COWS.

First prize £10, with extra prize £20 as best shorthorn, GOLD MEDAL as best of all the cows, and silver medal as breeder, Lieutenant-Colonel Charles Towneley, Towneley Park, Burnley, Lancashire (had one calf).

Second, £5, Mr. Robert Swinnerton, Weddington, Nuneaton (had one calf).

Highly commended, Viscount Hill, Hawkstone, Shropshire (had three calves), and Sir Thomas Whichcote, Bart., Aswarby Park, Falkingham, Lincolnshire (had one live calf and one dead).

The Class generally commended.

CLASS VIII.—HEIFERS.

First prize £10, and silver medal as breeder, Lord Feversham, Duncombe Park, Helmsley, Yorkshire.

Second, £5, Mr. Robert Gell, Grimston Hill, York.

Highly commended, Mr. Richard Thomas, Ryton, Dorrington.

Commended, Viscount Hill, and Mr. Joseph Phillips, Ardington, Wantage.

DEVONS.

Class IX.—Oxen or Steers.

First prize £10, with £20 extra prize as best Devon, Lord Ward's prize of £25 for best ox bred *and* fed by an exhibiter, and silver medal as breeder, Earl of Leicester, Holkham Hall, Norfolk.

Second, £5, The Earl of Leicester.

Highly commended, Mr. William Heath (for two oxen), and Mr. Joseph Potter, Witton, near Birmingham.

The Class generally commended.

Class X.—Devon Steers.

First prize £10, and silver medal as breeder, the Earl of Aylesford, Packington.

Second, £5, His Royal Highness the Prince Consort.

Commended, the Earl of Leicester, and Mr. Thomas White Fouracre, Durston, near Taunton.

Class XI.—Cows.

First prize, £10, Mr. John C. Halse, Molland, Devonshire; silver medal to breeder, Mr. Thomas Halse, Molland (had five calves).

Second, £5, Mr. William Heath, Ludham (had two calves).

Highly commended. Mr. Abraham Umbers, Weston Hall, Leamington (had six calves); and Mr. James Hole, Knowle House, Dunster, Somerset (had one calf).

Class XII.—Heifers.

First prize, £10, His Royal Highness the Prince Consort; silver medal to breeder, Mr. James Hole, Knowle House.

Second, £5, Mr. Thomas White Fouracre, Durston, near Taunton.

LONG-HORNS.

Class XIII.—Oxen or Steers.

Prize, £5, Mr. R. H. Chapman, Upton, near Nuneaton; silver medal to breeder, the late Mr. Samuel Burbery, Wroxhall, Warwick.

Class XIV.—Cows or Heifers.

First prize, £10, Mr. Joseph Holland Burbery, Kenilworth; silver medal as breeder, the late Mr. Samuel Burbery (had one calf).

Second, £5, Mr. W. T. Cox, Spondon Hall, Derby (had three calves).

OTHER PURE BREEDS AND CROSS-BRED ANIMALS.

Class XV.—Fat Oxen or Steers.

First prize, £10, Mr. Richard Thomas Ryton, Dorrington, Shropshire; silver medal to breeder, Mr. J. K. Smith, Radbrook, near Shrewsbury (Short-horn, Hereford).

Second £5, Lieutenant-Colonel Towneley (Cross-bred).

Class XVI.—Fat Cows.

First prize, £10, Mr. Robert Swinnerton, Weddington, Nuneaton; silver medal to breeder, Mrs. Caroline Williams Bedworth, Nuneaton (Cross-bred—had one calf).

Second, £5, Mr. Richard Machin, Papplewick, Nottinghamshire (Long-horn and Short-horn cross—had one calf).

Class XVII.—Fat Heifers.

First prize £10, and silver medal as breeder, the Duke of Beaufort, Badminton, near Chippenham, Wilts (West Highland Scotch).

Second, £5, the Duke of Beaufort (a cross between a West Highland Scotch cow and a Devon bull).

Class XVIII.—Scotch Oxen or Steers.

First prize, £10, Mr. Ralph Sneyd, Keel Hall, Staffordshire (West Highland).

Second, £5, Mr. Ralph Sneyd (West Highland).

WELSH BREEDS.

Class XIX.—Oxen or Steers.

First prize, £10, Mr. William Heath, Ludham.

Second, £5, Mr. Richard Doig, Surucy Farm, Long Buckby, Daventry, Northamptonshire.

EXTRA CLASSES.

(For Animals not qualified to compete in any of the preceding Classes).

Class XX.—Oxen or Steers.

Prize £5, and silver medal as breeder, Viscount Dillon, Ditchley Park, Enstone, Oxfordshire.

Class XXI.—Cows or Heifers.

Prize £5, Earl of Lichfield, Shugborough, (shorthorn, had one calf).

SHEEP.

Judges:—Mr. Edward Gough, Gravel Hill, Shrewsbury.
Mr. Joseph Holland Burbery, Kenilworth, Warwick.
Mr. John Moon, Hursthourne Priors, Whitchurch, Hants.

Class XXII.—Leicesters.

(Fat Wethers, not exceeding twenty-two months old.)

First prize £10, extra prize £10 as best of all the Long-wools, and silver medal as breeder, Mr. George Saville Foljambe, Osberton Hall, Worksop, Notts.

Second, £5, Mr. Foljambe.

Highly Commended, Mr. John Hopper, Brompton, Pickering, Yorkshire.

Class XXIII.—Leicesters.

(Fat Wethers, exceeding twenty-two, but not exceeding thirty-four months old.)

No entry.

Class XXIV. — Long-woolled Sheep, not being Leicesters.

(Fat Wethers, not exceeding twenty-two months old).

First prize £10, and silver medal as breeder, Mrs. West, Green Hill Farm, Bletchington, Oxfordshire (Cotswold).

Second, £5, Mrs. West.

Commended, Mr. William Hewer, Sevenhampton, Highworth, Wilts.

Class XXV.

(Fat Wethers, exceeding twenty-two, but not exceeding thirty-four months old).

No entry.

Class XXVI.—South and other Down Sheep.

(Fat Wethers, not exceeding twenty-two months old).

First prize £10, and silver medal as breeder, Lord Walsingham, Merton Hall, Thetford, Norfolk.

Second, £5, Lord Walsingham.

Class XXVII.—South and other Down Sheep.

(Fat Wethers, exceeding twenty-two, but not exceeding thirty-months old).

First prize £10, extra prize £10 as best of all the Short-wools, and silver medal as breeder, Lord Walsingham, Merton Hall, Thetford, Norfolk.

Second, £5, Sir Robert George Throckmorton, Bart., Buckland, Faringdon.

Class XXVIII.—Shropshire and other Black or Grey-faced Short-woolled Sheep.

(Fat Wethers, not exceeding twenty-two months old.)

First prize £10, and silver medal as breeder, Mr. Henry Smith, jun., Sutton Maddock, Shiffnal, Shropshire.

Second, £5, Mr. J. B. Green, Marlow, Leintwardine, Ludlow.

Highly Commended, Mr. Holland, M.P., Dumbleton Hall, Evesham; Mr. William Orme Foster, M.P., Kinver-hill Farm, Stourbridge; and Mr. J. B. Green, Marlow (for another pen).

Class XXIX.—Shropshire and other Black or Grey-faced Short-woolled Sheep.

(Fat Wethers, exceeding twenty-two, but not exceeding thirty-four months old).

First prize £10, and silver medal as breeder, Mr. W. O. Foster, M.P.

Second, £5, Mr. T. C. Whitmore, Apley Park, Bridgnorth.

Highly commended, the Earl of Aylesford and Mr. H. Smith, jun., Sutton Maddock.

Class XXX.—Cross-Bred Sheep.

(Fat Wethers, not exceeding twenty-two months old.)

First prize, £10, silver medal as best cross-breds, and silver medal as breeder, Mr. Adam Corrie Keep, Wollaston, Wellingborough (South Down and Cotswold).

Second, £5, the Earl of Leicester (Down and Leicester).

Highly commended, the Earl of Leicester (Down and Leicester).

Commended, Mr. John Woolston, Wellingborough (South Down and Cotswold); and Mr. John Bryan, Southleigh, near Witney, Oxfordshire (Cross-bred or Oxfordshire Down).

CLASS XXXI.—FAT WETHERS, EXCEEDING TWENTY-TWO, BUT NOT EXCEEDING THIRTY-FOUR MONTHS OLD.

First prize, £10, and silver medal as breeder, Mr. A. C. Keep, Wollaston, Wellingborough (South Down and Cotswold).

Second, £5, Mr. A. C. Keep, (South Down and Cotswold).

PIGS.

JUDGES:—Mr. Edward Gough, Gravel Hill, Shrewsbury.
Mr. Joseph Holland Burbery, Kenilworth, Warwickshire.
Mr. John Moon, Hurstbourne Priors, Whitchurch, Hants.

CLASS XXXII.—FAT PIGS.

(Fat Pigs of one litter, not exceeding ten months old.)

First prize, £10, and silver medal to breeder, Mr. T. R. B. Cartwright, Aynhoe, near Brackley, Northamptonshire.

Second, £5, Mr. Henry William Dashwood, Dunstew, near Woodstock, Oxfordshire.

CLASS XXXIII.—FAT PIGS.

(Fat Pigs of one litter, not exceeding fifteen months old.)

First prize, £10, and silver medal to breeder, Mr. Richard Benyon, Englefield House, Reading.

Second, £5, the Countess of Chesterfield, Bretby Hall, Burton-upon-Trent.

Highly commended, Lord Leigh, Stoneleigh Abbey, Kenilworth; and Mr. William James Sadler, Calcutt and Bentham, near Crickdale, Wilts.

Commended, His Royal Highness the Prince Consort; and Mr. G. B Morland, Chilton Farm, near Abingdon.

CLASS XXXIV.—FAT PIG.

(Exceeding Fifteen Months Old.)

First prize, £6, and silver medal as breeder, Mr. George Mangles, Givendale, Ripon, Yorkshire (Bendigo).

Second, £3, Mr. James John Whiteman, Brownsover, Warwickshire.

Highly commended, Mr. William Hemming, Coldicott, near Moreton-in-the-Marsh.

Commended, Mr. William Parkes, sen., Camp Hill, Birmingham, (for 2 pigs); Mr. Geo. Mangles, (for another pig); and Mr. Henry Thornley, Marston Hall, Birmingham.

CLASS XXXV.—PIGS OF A LARGE BREED.

(Five Pigs of one litter, exceeding three, and not exceeding six months old.)

First prize, £10, and silver medal as breeder Mr Joseph Smith, Henley-in-Arden, Warwickshire (Berkshire).

Second, £5, Sir F. L. H. Goodricke, Bart., Studley Castle.

Silver medals to Mr. William Hewer, Sevenhampton, Highworth, Wilts (Berkshire); Mr. T. B. Wright, Great Barr, Staffordshire (Berkshire); Mr. Edward H. France, Ham Hill, near Worcester; Mr. Walter John Breach Scott, Queen's Hotel, Birmingham; and Mr. Henry Howell, The Firs, Green Lanes, Birmingham (Berkshire).

Highly commended, Mr. James Atty, Rugby; Mr. William Bradley Wainman, Carhead, Cross Hills, Yorkshire; Mr. Wm. Endall, Henley-in-Arden, Warwickshire (Improved Tamworth); and Mr. Robert Overbury, Henley-in-Arden, Warwickshire (Berkshire).

CLASS XXXVI.—PIGS OF A SMALL BREED.

(Five Pigs of one litter, exceeding three, and not exceeding six months old.)

First prize, £10, and silver medal as breeder, His Royal Highness the Prince Consort.

Second, £5, Mr. Samuel Wiley, Brandsby, York.

Silver medals to Colonel Pennant, Penrhyn Castle, Bangor, North Wales; Mr. Robert Harrison, Watson, Bolton Park, Wigton, Cumberland (2); Mr. Samuel Wiley; Mr. George Mangles; and Mr. George Garne, Churchill Heath, Chipping Norton.

Highly commended, Captain Robert Gunter, Wetherby Grange, Wetherby, Yorkshire; and His Royal Highness the Prince Consort.

The following Certificates were given in reference to the pens of Pigs disqualified:

"Birmingham, Nov. 28th, 1857.

"We hereby certify that one of the pigs in Pen No. 196 has a state of its dentition which indicates that the animal is about eleven months old.

(Signed) "JAMES B. SIMONDS.
"ROBERT L. HUNT."

"Birmingham, Nov. 28th, 1857.

"We hereby certify that the state of the dentition of the pigs, Pen No. 193, indicates that the animals exceed the ages named in the exhibitor's certificate.

(Signed) "JAMES B. SIMONDS.
"ROBERT L. HUNT."

"Birmingham, Nov. 28th, 1857.

"We hereby certify that the dentition of the pigs, Pen No. 239, shows that the animals are of greater age than represented in the exhibitor's certificate.

(Signed) "JAMES B. SIMONDS.
"ROBERT L. HUNT."

PRIZES FOR ROOTS.

JUDGE.—MR. J. MATTHEWS, Edgbaston House, Birmingham.

CLASS I.—A SILVER CUP VALUED TEN GUINEAS, OFFERED BY THE MAYOR OF BIRMINGHAM, FOR THE BEST COLLECTION OF THE FOUR FOLLOWING VARIETIES: LONG MANGOLD WURZEL, GLOBE MANGOLD WURZEL, SWEDES, AND CARROTS; SIX ROOTS OF EACH TO BE SHOWN.

Mr. Richard Benyon, Englefield House, Reading.

Highly commended, Mr. A. W. Johnson, Manor House, Gunnersbury, Ealing, Middlesex.

Commended, Mr. Robert Fellowes, Bitteswell Hall, Lutterworth; the Rev. Thomas Stevens, Bradfield Rectory, Reading; and Mr. J. B. Starkey, Spye Park, Chippenham.

CLASS II.—LONG MANGOLD WURZEL.

First prize, £2 2s., Mr. Charles Pratt, Stratford-upon-Avon.

Second, £1 1s., Mr. A. H. Johnson, Manor House, Gunnersbury.

Highly commended, Mr. J. H. Horsburgh, Bradfield, Reading.

Commended, Mr. T. T. Stainton, Horsell, Woking, Surrey; Mr. Richard Benyon; and Mr. Saml. Robinson, Shaw House, Melbourne.

CLASS III.—GLOBE MANGOLD WURZEL.

First prize, £2 2s., Mr. J. H. Horsburgh, Bradfield, Reading.

Second, £1 1s., Mr. Richard Benyon.

Commended, Mr. A. H. Johnson (for two lots).

CLASS IV.—SWEDES OF ANY VARIETY.

First prize, £2 2s., Mr. Wm. Fletcher, Radmanthwaite, Mansfield.

Second, £1 1s., Mr. Robert Harrison Watson, Bolton Park, Wigton, Cumberland.

CLASS V.—COMMON TURNIPS.

First prize, £2 2s., Mr. Geo. Mangles, Givendale, Ripon, Yorkshire.

Second, £1 1s., Mr. Samuel Druce, jun., Abbey Farm, Eynsham, near Oxford.

CLASS VI.—CARROTS OF ANY VARIETY.

First prize, £2 2s., Mr. George Saville Foljambe.

Second, £1 1s., Mr. George M'Cann, Graham House, Malvern.

Highly commended, Mr. Wm. Lay, Place Farm, Chilton, near Abingdon.

Commended, Mr. George M. Kettle, Dallicott House, Bridgnorth.

CLASS VII.—OX CABBAGE.

First prize, £2 2s., Mr. Samuel Robinson, Shaw House, Melbourne.

Second, £1 1s., Mr. Robt. Fellows, Bitteswell Hall, Lutterworth.

CLASS VIII.—POTATOES.

First prize, £2 2s, Lord Leigh, Stoneleigh.
Second, £1 1s., Mr. James Howard, Tarleton, Chorley, Lancashire.

The JUDGES for POULTRY were:

Mr. George James Andrews, Dorchester.
Mr. John Baily, Mount-street, Grosvenor-square, London.
Mr. Thos. Challoner, Burnt Leys, Whitwell, near Worksop.
Mr. Edward Hewitt, Eden Cottage, Sparkbrook, near Birmingham.
The Rev. Robert Pulleine, the Rectory, Kirby Wiske, near Thirsk.

FOR PIGEONS.

Mr. T. J. Cottle, Pulteney-villa, Cheltenham.
Mr. Edward Hale, Handsworth.

REFEREE FOR THE AGES OF PIGS.

Professor Simonds, Royal Veterinary College, London.

VETERINARY INSPECTOR AND GENERAL REFEREE.

Mr. R. L. Hunt, Cannon-street, Birmingham.

The Birmingham exhibition has grown into such importance in nine years, that it deserves even an additional notice beyond that embraced in our regular report of the Meeting.

In the first place, what a magnificent building for the purpose is that Bingley-hall: with ample room and every convenience of arrangement, and even with elegance in the construction of the roof and the array of pillars, in the ornamentation and blazing chandeliers! And this year how comfortably have the enlarged numbers of stock and poultry been accommodated, by distributing the stalls of roots and seedsmen's specimens throughout various parts of the great area! Would that a similarly covered space existed in the metropolis! It would be most valuable and useful during other months than December. Cannot a site be found? where is the spirit to begin; and who will find the bricks and timber? Does the Smithfield Club answer best to a coaxing, or a roasting? Or is it quite bold enough to venture on such a spec. (after the example of young Birmingham) were it only a little more liberally fed with funds?

Look at the show in Bingley Hall: we had 36 classes of stock—including 135 entries of cattle, against 109 last year; 53 of sheep, against 46 last year; and 103 of pigs, against 101 last year. There were 8 classes of roots—comprising 130 entries, against 119 last year: 69 classes of fowls, ducks, geese, and turkeys, with 1,498 pens of birds, against 1,416 last year. Six hundred exhibitors this year—an increase of 46 over last time—contributed toward the excellence of the show; and while we had the presence of the very highest class of fat stock and unsurpassed poultry, it is remarkable that so many of the honours were carried off by new competitors, or else by those previously low in the scale: an evidence this of the extension of first-class breeding and feeding; while the old standard prizemen keep up their pace of improvement.

In examining the different classes, we did not forget how good the Herefords were last year; what a greatly improved, and indeed unsurpassed show of Devons we had; while the Shorthorns, as a whole, were not so grand as on some other occasions. Yet, as a testimony to individual merit in different breeds, it should be remembered that, while the Shorthorn gained the gold medal, the Hereford and Devon prize steers were also the judge's candidates for it. Last year one gold medal went to Mr. Stratton's Shorthorn ox, and the other to Mr. Pitt's Hereford heifer; and this time Mr. Shaw's Hereford ox and Colonel Towneley's Shorthorn cow are similarly victorious. But, beside these gold medals, singling out the best ox or steer and the best cow or heifer "of any breed or age" (that is, the best in the Show), just as at Baker-street, a competition is also established between animals of the same breed, but of course of different sex—"extra prizes" being awarded to the best Hereford, the best Shorthorn, and best Devon; that is, to the most meritorious animal in each breed, no matter whether it be aged or young ox, steer, cow, or heifer. And this year Lord Ward (the President) has given a piece of ornamental plate for the best ox or steer of any breed or age, "bred, as well as fed, by the exhibitor;" besides which, there is a sweepstakes in the Hereford, Shorthorn, and Devon classes for the breeders who are also the feeders and exhibitors. Would not some new honours of this kind be advisable in the next Smithfield Club prize sheet?

We shall not enter, in this place, into any criticism of the various classes; but what a magnificent cow is that of Colonel Towneley! her breadth and depth are wonderful! her back, chine, and rump splendid. How compact she is—how level! and what a rare touch she has! Her girth is 8 feet 6 inches; and Mr. Swinnerton's second-prize cow, one year and five months older, girths just the same. The small Devons took the palm away from the large animals, as witness the first-prize ox, which girths 7 feet 9 inches; while the second-prize one girths 8 feet 1 inch, having a much deeper chest and a larger frame.

It was gratifying to find the Shropshire Down sheep come up in such force. This breed is fast rising in fame, in spite of their alleged special liability to foot-halt. Originally descended from a hardy mountain breed, and inheriting an excellent constitution, they are not only enabled to thrive on exposed moorlands, but on better pastures evince an unsurpassed rapidity of growth and a tendency to a heavy weight at an early age. In frame and symmetry they have been so improved as to be noted for deep chests, famous legs of mutton, and fine dark-brown heads; while their wool is of the first-class for its thick pile and length of staple. And equally pleasing was it to see such a splendid show of cross-bred sheep; Mr. Keep's beautiful and indeed wonderfully-fed wethers proving the value of the cross between Cotswold and Southdown. It should be noticed that this breeder's first-prize older sheep competed closely with his shearlings for the silver medal, the latter taking the honour principally on account of their age.

We were glad to see that the veterinary inspectors were unflinching in the discharge of their duties in the pig classes. In one class we saw a pen of most beautiful pigs, which would undoubtedly have gained the prize had they not been disqualified because "the state of their dentition" indicated that their age exceeds that stated in the exhibitor's certificate.

It is impossible to estimate too highly the value of the Birmingham Poultry Show, standing, as it does, alone and above all others; for even at the Crystal Palace Show, it must be remembered that the birds are not exhibited in all the glory of their winter plumage, as they are here; and besides, this year's chickens have time to develope themselves before the show. Bingley Hall is the best possible guide for poultry keepers; as the fowls, are all classified, their points of excellence or demerit reduced to a system, and their individual deserts determined by the men who best understand them. And the public are not simply taught which are the most profitable breed for different districts or purposes; but they are instructed in the more minute characteristics of each variety and in all the abstruse excellencies of a perfect speci-

men, which make poultry-fancying almost a science. Thus, high condition, quality, beauty of plumage, purity of race, and uniformity in the markings, combs, and other characteristics of the fowls, are taken into consideration by the judges, in a greater degree than mere weight, without these distinctions. And the immense number of pens of almost perfect birds proves the extent to which these shows have spread the knowledge of good breeding and proper management. With a view of weeding-out inferior poultry, which might degrade the exhibition into a mere market, there is a rule forbidding any exhibitor showing more than four pens of fowls, ducks, geese, or turkeys, or six of pigeons; the subscription for entry is high; an extra charge is levied on each pen shown; and 10 per cent. is charged on every sale effected in the Hall. Yet there are more exhibitors than last year, and fully three pens a-piece were sent in; some apparently managing also to monopolize room by parcelling the ownerships of their ducks or chickens among the junior members of their family. Every part of the show was most satisfactory and successful; and we would also offer a word of praise to the admirable arrangement of matter in the bulky catalogue. In addition to the descriptive particulars of the animal, birds, and specimen of produce (and bear in mind that the details of the cultivation and manuring of each lot of roots is published for our instruction, as well as the sorts of food given to the live stock), there is a separate index for each of the two great divisions of the show. In the first you find not only the name and address of each exhibitor, but whether he shows cattle, sheep, pigs, or roots, and also the "number" attached to each of his animals. In the other list are the poultry and pigeon exhibitors, with similar convenient references. Here, again, might not our Smithfield Club managers follow with advantage a society which has in so many respects imitated them?

GLOUCESTERSHIRE AGRICULTURAL SOCIETY.

The third annual exhibition was held at Cirencester, on Thursday, November 26th, when the following prizes were awarded—

SHORT-HORNS AND OTHER BREEDS, EXCEPT HEREFORDS AND DEVONS.

For the best Bull above two years old, the gift of the Right Hon. Earl Ducie, £10, Mr. William Hewer, Sevenhampton, near Highworth.

Second best, £5, Mr. William Slatter, Stratton, near Cirencester.

Commended.—Mr. W. A. Elston, Bugbrook, Weedon.

For the best Bull above one and under two years old, £10, Mr. Richard Stratton, Broad Hinton, near Swindon.

Second best, the gift of W. P. Price, Esq., M.P., £5, Mr. J. W. Brown, Uffcott, near Swindon.

For the best Bull, Cow, and their Offspring, £10, Mr. Richard Stratton, Broad Hinton, near Swindon.

Second best, £5, J. H. Langston, Esq., M.P., Sarsden House, Chipping Norton.

For the best cow, in-calf or in-milk, £6, J. H. Langston, Esq., M.P., Sarsdon House, Chipping Norton.

Second-best, £3, Mr. Richard Stratton, Broad Hinton, Swindon.

For the best pair of heifers, in-calf or in-milk, under three years old, bred by the exhibiter, £10, Mr. Richard Stratton, Broad Hinton, Swindon.

Second-best, £5, Mr. John Lane, Cirencester.

Commended, Mr. Edward Bowly.

For the best pair of breeding heifers, under two years old, bred by the exhibiter, £8, the gift of Edward Holland, Esq., M.P., Mr. Edward Bowly, Siddington House, Cirencester.

Second best, £4, Mr. T. R. B. Cartwright, Aynho, near Brackley.

Highly commended.—Mr. John Lane, and Mr. R. Stratton.

HEREFORDS AND DEVONS.

For the best Bull above two years old, £10, the gift of the Right Hon. Earl Bathurst, Mr. John Walker Westfield House, Holmer, Hereford.

Second best, £5, Mr. James Ackers, Prinknash Park, Painswick.

Commended.—Mr. J. E. Lloyd Hewer, jun.

For the best Bull above one and under two years old, the gift of Sir C. W. Codrington, Bart., M.P., £10, Mr. J. E. Lloyd Hewer, jun., Vern House, Hereford.

Second best, £5, Mr. Wm. Taylor, Showle Court, Lower Eggleton, near Ledbury.

For the best bull, cow, and their offspring £10, the gift of the Right Hon. Earl Beauchamp, Mr. William Perry, Cholstrey, near Leominster.

Second best, £5, Mr. W. G. Bennett, North Cerney, Cirencester.

For the best cow, in-calf or in milk, £6, the gift of Robert Stayner Holford, Esq., M.P., Mr. Wm. Stedman, Bedstone Hall, Aston-on-Clun, Shrewsbury.

Second best, £3, Mr. J. E. Lloyd Hewer, jun., Vern House, Hereford.

For the best pair of heifers, in calf or in milk, under three years old, bred by the exhibitor, £10, the gift of Robert Stayner Holford, Esq., M.P., Mr. William Stedman, Bedstone Hall, Aston-on-Clun, Shrewsbury.

Second best, £5, Mr. Thomas Pope, Horningsham, Warminster.

The whole of this class commended.

For the best pair of Breeding Heifers under two years old, bred by the exhibitor, the gift of James Ackers, Esq., £8, Mr. William Perry, Cholstrey, near Leominster.

Second best, £4, Mr. Thomas Pope, Horningsham, Warminster.

Highly commended.—Mr. William Taylor.

FAT CATTLE.

For the best Fat Steer of any breed, the gift of the Hon. W. L. Bathurst, £6, Mr. Aaron Pike, Mitton, near Tewkesbury.

Second best, £4, Mr. Richard Stratton, Broad Hinton, near Swindon.

For the best fat cow, having had a calf at its full time, £6, Mr. Thomas Garne, Broadmore Farm, near Northleach.

Second best, £4, Mr. Aaron Pike, Mitton, Tewkesbury.

LONG WOOLS.

For the best five breeding ewes not more than 35 months old, £8, the gift of the Hon. Ashley Ponsonby, Mr. William Smith, Bibury.

Second best, £4, Mr. Thomas Beale Browne, Hampen, Andoversford.

For the best five breeding theaves, not more than twenty-three months old, £8, Mr. Wm. Smith, Bibury.

Second best, £4, to the Royal Agricultural College, Cirencester.

Commended.—Mr. Thomas Beale Browne.

For the best five Ewe Lambs not more than 11 months old, £5, Mr. James Newman, Calmsden, Cirencester.

SHORT WOOLS.

For the best five Breeding Ewes not more than 35 months old, the gift of the Right Hon. Earl of St. Germans, £5, His Grace the Duke of Beaufort.

Second best, £2 10s., Sir Robert G. Throckmorton, Bart., Buckland, Faringdon.

For the best five Breeding Theaves not more than 23 months old, £5, Sir. Robert G. Throckmorton, Bart., Buckland, Faringdon.

Second best, £2 10s., Mr. Thomas Pope, Horningsham, Warminster.

CROSS BREED.

For the best five breeding theaves, not more than 23 months old, £5, Mr. William Hemming, Coldicott, near Moreton-in-Marsh.

Second best, £2 10s., Mr. John King Tombs, Langford, Lechlade.

FAT SHEEP.—LONG WOOL.

For the best three shearhogs not more than 23 months old, £5, to Mr. William Hewer, Sevenhampton, near Highworth.

Second best, £2 10s, to the Royal Agricultural College, Cirencester.

For the best five wether tegs not more than 11 months old, £5, Mr. James Newman, Calmsden, Cirencester.

For the best three fat ewes, £5, Mr. George Fletcher, Shipton, near Andoversford.

FAT SHEEP—SHORT WOOL.

For the best three shearhogs not more than 23 months old, £5, Mr. Edward Holland, M.P., Dumbleton Hall, near Evesham.

CLASS I.—FAT SHEEP—CROSS BREED.

For the best three shearhogs not more than 23 months old, £5, Mr. John Plumbe, Ashton Keynes, near Cirencester,

Second best, £2 10s., Mr. Charles Hobbs, Maisey Hampton, near Cirencester.

PIGS.

For the best boar pig under one year old, the gift of T. Gambier Parry, Esq., £4, Mr. Wm. Hewer, Sevenhampton, near Highworth.

Commended.—Mr. Edward Bowly.

For the best three sow pigs of the same litter under 4 months old, the gift of T. B. Lloyed, Esq., £4, Mr. J. H. Elwes, Colesbourne Park, Cirencester.

The whole of this class commended.

For the best sow pig for breeding purposes, the gift of J. H. Elwes, Esq., £3, Mr. Wm. Hewer, Sevenhampton, near Highworth.

For the best sow and pigs her own produce, the pigs under 10 weeks old, £3, Sir Robt. G. Throckmorton, Bart., Buckland, Faringdon.

HORSES.

For the best mare and foal (her own offspring) for agricultural purposes, £8, Mr. Henry Baily, Wallgaston, near Berkeley.

Second best, £4, Mr. Edward Holland, M.P., Dumbleton Hall, Evesham.

Commended—Mr. Samuel Bidmead.

For the best stallion, for agricultural purposes, above 2 years old, £10, Mr. William Edmonds, Wroughton, near Swindon.

For the best filly, for agricultural purposes, under 3 years old, the gift of Robert Gordon, Esq., £5, Mr. William Smith, Bibury.

Second best, £3, Earl of Radnor.

Commended—Mr. Richard Waine.

RUTLAND AGRICULTURAL MEETING.

Famous as the agriculturists of Rutland have been for the last 26 years for their exhibition of stock in the Riding House at Oakham, it is questionable whether a more splendid show of cattle of all kinds ever graced that building than took place at the anniversary on Wednesday, Dec. 2. It was acknowledged by many who have attended these gatherings for a number of years that a finer array of stock, both in regard to numbers and quality, was never seen in this county: so meritorious in every respect was the exhibition, that to say more in general praise would only detract from the excellence of what might be justly termed a "little Smithfield." If we may venture, however, to notice individual claims, the first-class steer shown by Mr. Wortley, of Ridlington, and which took the prize of 15 sovs., was generally acknowledged to be a fine specimen. Mr. Wortley was very successful this year, having taken four prizes in this department. The second prize ox shown by Mr. Lynn, of Stroxton, also attracted considerable notice. In class 2 the prize ox, 3 years and 9 months old, shown by the Marquis of Exeter, came in for its share of well-deserved admiration. It is intended to exhibit this beautiful animal at Leicester and Smithfield. Next in order stood (in class 3) a first-rate steer shown by R. W. Baker, Esq., of Cottesmore; this animal, although small, was perfect in every respect, and met with a very large share of commendation from practical men. A one-year-and-nine-months-old heifer, in extra stock, belonging to C. O. Eaton, Esq., was a first-rate animal, and obtained the silver medal given by the Duke of Rutland. There was a large show of sheep, and in these classes a spirited competition took place between Mr. C. J. Bradshaw, of Burley, and Mr. Wortley: the former, however, seems to have inherited the spirit of his father, who for a number of years figured so conspicuously and successfully in this department at Rutland and elsewhere. On the present occasion Mr. Bradshaw, jun., carried off four first prizes and one second prize; Mr. Wortley obtained second prizes in three classes. The most extraordinary specimen in the show was a Leicester ewe (bred by Mr. R. L. Bradshaw, and exhibited by his son), which competed for the silver medal offered by the tradesmen of Oakham; this animal was acknowledged to be the best ewe that has been seen at any of these shows: it will be entered for competition at Smithfield, and will, we think, be a match for any one of its kind that can be taken to the metropolis. In the same class was a ewe, 13 years and 8 months old, exhibited by Mr. T. Swingler, of Langham; this, considering its great age, was allowed to be a first-rate specimen. There was a large number of hunters for the premium given by the Marquis of Exeter, but nothing to call for particular notice was exhibited. The show of pigs was limited, but the animals were of a superior kind; one, a year and three months old, exhibited by R. W. Baker, Esq., as extra stock, was a perfect specimen of the porcine breed, and was highly commended, In the root-crop department the increase of prizes brought a corresponding increase in the number of competitors. Some first-rate turnips, mangolds, and cabbages, were shown outside the gates. The first prize in class 8 was awarded to the Hon. Col. Lowther; and Messrs. Painter, of Burley, carried off the silver cup given by the Hon. G. J. Noel, M.P., for swedish turnips in quantities of not less than ten acres.

During the morning a large number visited the Riding-house. A good sum was taken at the doors. Amongst the company we noticed Lord Aveland, Viscount Campden, the Hon. Col. Lowther and Miss Lowther, the Hon. G. J. Noel, M.P., the Hon. G. H. Heathcote, M.P., Geo. Finch, Esq., Gen. Fludyer, R. W. and W. H. Baker, Esqs., Jno. Eagleton, Esq., the Rev. H. Fludyer, Rev. Wm. Jackson, Rev. T. Davidson, &c., &c.

THE JUDGES.

STOCK.—Thomas Townsend, Esq., Ilmorton-hall, Warwickshire; Chas. Bosworth, Esq., Dishley, Leicestershire; R. B. Richardson, Esq., West Firsby, Lincolnshire.

HUNTING HORSES.—S. Hunt, Esq.; W. W. Tailby, Esq.; W. A. Pochin, Esq.

VEGETABLES.—Mr. R. Ward, Harringworth; Mr. J. Grimes, Pickworth; Mr. J. Linney, Thistleton.

AWARD OF PREMIUMS.

Oxen or steers, of any breed or weight, under five years of age. Open to all England. First prize, £15, to Mr. E. Wortley, of Ridlington; second, £7, to Mr. R. Lynn, of Stroxton; W. De Capell Brooke, Esq., and Mr. R. Jones commended.

Oxen or steers, of any breed or weight, under four years of age. First prize, £10, to the Most Noble the Marquis of Exeter, K.G.; second, £5, W. De Capell Brooke, Esq., of Geddington-grange.

Cows or heifers, of any breed, age, or weight. Open to all England. First prize, £10, to R. W. Baker, Esq., of Cottesmore; second, £5, to Mr. E. Wortley, of Ridlington; W. De Capell Brooke, Esq., and Sir Thos. Whichcote, Bart., commended.

To the owner, being a tenant farmer, of the best steer, under three years of age. First prize, £7, to Mr. Thos. Swingler, of Langham; second, £3, to Mr. E. Wortley, of Ridlington.

To the owner, being a tenant farmer, of the best steer, under two years of age. First prize, £5, to Mr. R. Lynn, of Stroxton; second, £3, to R. W. Baker, Esq., of Cottesmore.

To the owner, being a tenant farmer, of the best heifer, above two and under three years of age. First prize, £6, to Mr. C. J. Bradshaw, of Burley-on-the-Hill; second, £3, to Mr. T. W. Fowler, of Exton; Mr. E. Wortley and Mr. J. Woods commended.

To the owner, being a tenant farmer, of the best heifer, under two years of age. First prize, £4, to Mr. T. Chapman of Whitwell; second, £2, to Mr. E. Wortley, of Ridlington; Mr. T. Swingler and Mr. J. Pears commended.

Offered by Stafford O'Brien, Esq.

To the owner, being a tenant farmer, of the best cow in milk, £5, to C. O. Eaton, Esq., of Kelthorpe; second, £2, to R. W. Baker, Esq., of Cottesmore.

To the exhibitor of the best bull, above two-and-a-half and under five years old, £5, to Mr. R. Lynn, of Stroxton; second, £3, to Mr. T. Suter, of Brook.

To the exhibitor of the best bull, above one and under two-and-a-half years old, £5, to the Right Hon. the Earl of Gainsborough; second, £3, to Mr. R. Lynn, of Stroxton.

To the exhibitor of the best mare, £3, to Mr. J. Hack, of Egleton.

To the exhibitor of the best yearling gelding or filly for agricultural purposes, £3, to Mr. W. Hammond, of Barrow.

Offered by the Right Hon. the Earl of Gainsborough.

(To the tenant occupier of not more than thirty acres of land in the district.)

To the owner of the best cow in milk, £5, to Mr. J. Williamson, of Langham; second, £2, to Mrs. J. Harris, of Langham; Mr. R. Mills, of Whitwell, commended.

To the owner of the best heifer, under two years and-a-half old, £4, to Mrs. J. Harris, of Langham; second, £2, to Mr. J. Edgson, of Langham; Mr. P. Healey, of Burley, commended.

To the owner of the best heifer calf, £2, to Mr. W. Hubbard, of Langham; second, £1, to Mrs. J. Harris, of Langham.

Offered by the Right Hon. Lord Aveland.

Long-woolled fat wether sheep, £10, to Mr. C. J. Bradshaw, of Burley-on-the-Hill; second, £5 (offered by the Society), to Mr. E. Wortley, of Ridlington.

Offered by the Society.

Long-woolled fat wether sheep, £7, to Mr. C. J. Bradshaw, of Burley-on-the-Hill; second, £4, to Mr. E. Wortley, of Ridlington.

To the owner of the best breeding ewes, £5, to Mr. C. J. Bradshaw, of Burley-on-the-Hill; second, £3, to Mr. T. Swingler, of Langham.

Long-woolled theaves, £4, to Mr. C. J. Bradshaw, of Burley-on-the-Hill; second, £2, to the Hon. Colonel Lowther, of Barleythorpe.

Long-woolled wether lambs, £3, to Mr. E. Wortley, of Ridlington; second, £2, to R. W. Baker, Esq., of Cottesmore.

To the owner of the best long-woolled ewe lambs, £3, to R. W. Baker, Esq, of Cottesmore; second, £2, to Mr. C. J. Bradshaw, of Burley-on-the Hill.

To the owner of the best pig of any breed, £4, to Mr. T. Bowles, of Great Hale; second, £2, to R. W. Baker, Esq., of Cottesmore.

To the owner of the best fat pig, £3, to Mr. T. Suter, of Brook; second, £1, to Mr. W. Benskin, of Rearsby.

Offered by the Right Hon. the Earl of Gainsborough.

To the owner of the best fat pig, £2, to Mr. J. Stimson, of Egleton.

Offered by the Society.

To the owner of the best in-pigged or suckling sow or yelt, £2, to Mr. T. Rudkin, of Langham Lodge; the Right Hon. the Earl of Gainsborough commended.

Offered by the Most Hon. the Marquis of Exeter.

To the owner of the best half-bred four years old hunting mare or gelding, £10, to Mr. G. Tipping, sen., of Saithy; second (offered by gentlemen of the Cotteamore Hunt), £5 to Mr. P. Healey, of Manton.

Offered by his Grace the Duke of Rutland.

To the exhibitor of the best beast shown as extra stock, a silver medal, value £3, to C. O. Eaton, Esq., Tixover Hall; W. R. Morris, Esq., of North Luffenham, W. De Capell Brooke, Esq., of Geddington Grange, Mr. R. Lynn, of Stroxton, Mr. C. Chapman of Exton, commended.

Offered by the Tradesmen of Oakham.

To the exhibitor of the best sheep shown as extra stock, a silver medal, value £3, to Mr. J. C. Bradshaw, of Burley-on-the-Hill; Mr. R. L. Bradshaw, jun., Tinwell, Mr. R. Lynn, of Stroxton, Mr. T. Swingler, Langham, Mr. E. Wortley, of Ridlington, commended.

EXTRA STOCK.

R. W. Baker, Esq., of Cottesmore, a pig, one year and three weeks old, bred and fed by himself on wheat and barley meal, commended.

ROOTS AND VEGETABLES.

Offered by the Right Hon. Viscount Campden.

For Swedish turnips cultivated on any system, £7, to the Hon. Colonel Lowther, of Barleythorpe; second, £3, to Mr. W. Berridge, of Barrow.

Offered by the Hon. Gerard James Noel, M.P.

For the best specimen of Swedish turnips, a silver cup, value £10, to Messrs. J. and R. Painter, of Burley.

Offered by the Society.

For the best specimen of mangold wurtzel, £2, to Mr. T. Suter, of Brooke.

Offered by the Hon Roden Noel.

For best specimen of mangold wurtzel, £3 to Mr. T. Godfrey, of Glaston Lodge.

Offered by the Society.

For the best specimen of cabbage, £1, to W. Fabling, Esq., of Burley.

Offered by the Tradesmen of Oakham.

For the best specimen of white turnips, £7, to Mr. J. G. Bosworth, of Greetham.

Offered by R. W. Baker, Esq.

For the best specimens of ten Swedish turnips, mangold, wurtzel, and cabbages, 10s. each. Turnips, Messrs. Painter; mangolds, Mr. Fabling; and cabbages, Mr. Rudkin.

ENGLAND WILL NEVER BE FARMED AS IT OUGHT TO BE, UNTIL WE HAVE A TENANT-RIGHT BY LAW.

SIR,—The old adage says, "Out of evil cometh good;" and the case of Mr. Breedon Everard, of Groby Hall, Leicestershire, will open the ears and eyes of thousands of farmers in Great Britain, and cause them to *think* for *themselves*, and not to lay out their money so freely as Mr. Everard has done, upon the estates of others, without tenant-right, alias justice for unexhausted improvements made on the farm by the tenant. It is plain Mr. Everard has ruined himself by improving the estate of a noble lord, after which he is turned out by his lordship without stating any reason why, or allowing him compensation for the vast improvements made on the farm. In the *Mark Lane Express* of the 26th October, it was stated that Mr. Everard "had, in fact, in a space of five years, laid out £5,000 in improving a farm of something over 300 acres." The above treatment of the noble lord to his diligent and admirable tenant, in the great age of discovery and improvement is monstrous: such a feudal system must soon either be ended or mended. The tide of reason long delayed, long checked and obstructed, has nevertheless set in, in North Lincolnshire, in the shape of tenant-right, which is wise, just, reasonable and profitable, but more so to the landlord than the tenant. Lincoln Heath, and the Lincolnshire wolds, for instance—a century back, rabbit warrens and wildernesses the principal part of them—what do they produce now under tenant-right? Why great crops of corn, clover, and turnips, and some of the heaviest-woolled sheep in the Kingdom. The great improvement of the said wild land under tenant-right is a fine example to all the world. I hope the Groby Hall case will be the means of causing a tenant-right to become the law of the land, to protect such useful and ornamental tenants as Mr. Everard.

SAMUEL LEMMON.

Peterborough, Nov. 5.

THE SMITHFIELD CLUB FAT CATTLE SHOW.

CATTLE.

As very erroneous impressions of the relative numerical strength of the different cattle classes, as compared with last year, may arise from mere inspection and recollection, we give the following figures, stating in the closest form which breeds have come up in unwonted force, and which of the new classes have contributed most to the increase of our present show. The entries were:

	1855.	1856.	1857.
Devons	17	21	32
Herefords	20	21	36
Shorthorns	40	42	43
Scotch, Irish, and Welsh	16	13	18
Other pure breeds	3	18	22
Cross-bred	7	12	8
Extra	9	13	17
Total	112	140	176

An increase, it appears, of one-third, both in the Hereford and Devon classes, has been the principal item in swelling the catalogue and filling the show-yard, though the Shorthorns still remain a long way ahead of the other breeds. The total number of cattle is very much greater than on any other occasion.

As to excellence, we have no hesitation in pronouncing this exhibition the best ever collected together in Baker-street Bazaar. Class after class presented an array of animals of remarkably high character, with rarely an inferior beast; and, as we might anticipate from the extension of good breeding of late years, the quality is almost universally of a superior description, and the huge monstrosities of fat once wondered at and ridiculed have given place to animals of a more profitably-feeding, early-fattening, and valuable kind. The standard of merit is not now simply the amount of flesh, except in the judgment of some old-school authorities, but the symmetry, quality, and valuable characteristics of the animal are taken into consideration, notwithstanding the circumstance of this Show being purposely designed for fat stock intended for the butcher. And we trust this principle will be persevered in—namely, to encourage such a fatness as may indicate the profitable nature of a breed, rather than mere weight, regardless of expense and time wasted in its attainment.

As to individual merit, we must own that, while the universal excellence proves how our various breeds are progressing, instead of deteriorating, the two best animals in the yard cannot be set up as nobler and more magnificent specimens than were ever seen before. If we were to compare the gold-medal ox or cow this year with those of many years back, we should undoubtedly find that a great advance has been made; but to expect that every year's prize animal is absolutely to eclipse the preceding one, is to consider breeding as purely mechanical. Whereas Nature bestows her gifts of form and beauty, and constitution and kindly habit, capriciously, as far as world-renowned marvels of excellence are concerned, and sometimes only at rare intervals gives us a Master Batterny or a Durham Ox. Hence the relative merit of individual animals from one year to another is of less importance than the amount of improvement or otherwise marking an entire class, or, indeed, a whole show. And, of course, the larger the number of first-class animals bred, the greater the chance of obtaining an ox more perfect or astonishing than the world has yet seen. Now we do not at all detract from the merits of Mr. Wortley's gold-medal ox when we say that there have been other animals which are remembered as being grander in their day and generation. By affirming that the best ox once was better than the best is now, we are not implying the deterioration of all; because, now, the prize animal is not so far beyond all compeers as he used to be—or, at any rate, there is far greater merit in every beast in his class than was the case a very little time back.

The prize Shorthorn ox will remind many persons of the famous Durham ox, and is remotely descended, we hear, from Earl Spencer's celebrated stock. What an extraordinary length and breadth, and yet most beautiful symmetry and compactness of form; his chine and ribs most wonderfully expanded, his immense weight of flesh most evenly laid on, and of first-class quality; and his head and bone fine, and very handsome. The only deficiency appears in his thigh and twist, which might have been better in proportion. His measurement is extraordinary, the girth being no less than nine feet two inches, and the length nearly six feet. Now that Mr. Wortley has made such a glorious *debut* at Baker-street, winning golden opinions with his real golden honours, and also, in addition, a third prize for his Shorthorn cow, likewise of his own breeding, we hope to welcome him in future as an annually successful competitor.

Last year the Shorthorns were obliged to yield one of the gold medals to Mr. Heath's superb Devon; but the year before, they carried off both, just as on the present occasion. Colonel Towneley's splendid cow, four years and one month old, and having had one calf, is far before any other animal in her exceedingly good class, and is, indeed, one of the finest we ever saw; not, however, for an immense frame or an extravagant degree of over-fatness, but because of her level and regular feeding, her unsurpassed touch and quality of meat, united to a faultless symmetry, beauty, fine offal, and neat head. But the visitors to Salisbury, York, Birmingham, and elsewhere, know her so well that we need not extend our expression of admiration. We would only add, that if any proof were wanted of the importance of fat stock shows, it is here in the fact that an animal of the very purest and best breed has won the day against all others, in the production of the largest quantity of most valuable beef. But is she a *bona fide* fat animal for the butcher? Or will she be taken home, and, if possible, again used as a breeding cow? Colonel Towneley also gains a second prize for an exceedingly good steer in the cross or mixed-breed class; this steer and the cow being the only animals exhibited by him.

The show of Shorthorns, as a whole, was very satisfactory; and we particularly admired the class for steers or oxen above three years old, comprising some especially good animals, and the class of cows which contained some amazingly good and meritorious. Yet it will be observed in the list of awards that the judges have given the Shorthorns little more encouragement or approval than they were compelled to administer, only two commendations being accorded—one to Lord Southampton's ox, and the other to Mr. Garne's white cow The latter is very handsome, very fat, and had she been less patchy, and with more meat on her neck, would have been entitled to a prize.

In the steer class, Mr. Lynn's prize animal has a wonderfully good fore-quarter, but struck us as being

defective about the first rib, and also on the hip. Earl Spencer's second-prize steer is a very good one; and Mr. Joseph Stratton's third-prize steer has great substance, though deficient in some points. Mr. Richard Stratton's steer in this class beat Earl Spencer's at Birmingham; but is certainly inferior in size and not superior in character. Mr. Brooke's second-prize ox and Mr. Roberts's third-prize ox are both useful and good beasts; the former, however, too patchy on the loin for our taste, and neither of them coming at all up to comparison with the magnificent Ridlington ox that has vanquished them. Mr. Cook's ox, five months older than Mr. Wortley's, is exceedingly large, and weighty, having great depth and length, but nothing like its breadth of chine and fore-quarter. Mr. Rushbrooke's is a very heavy good animal; as also that shown by Viscount Emlyn, and another shown by the Earl of Lonsdale. Mr. Barton's enormous beast is worth noting for his colossal frame; but very deficient in meat and quality.

In the heifer-class, Mr. Phillips's first-prize heifer is certainly the tallest and biggest; but considering that a first-prize female at any rate ought to be symmetrical, we do not like the chine or fore-quarter, though her hind-quarter is very good. Two other white heifers—one of the Earl of Radnor (taking the second prize), and the other bred and fed by Mr. Baker (which has been left without any recognition)—have occasioned considerable discussion as to the judges' award; the latter is very pretty and uniform in her proportions, and while not equal to the other in chine and neck-vein, rib and flank, is of greater size, and much better in loin, thigh and twist, and only three months older. Mr. Thomas's white heifer is very fleshy, having a wonderfully fat back; but we have here an evidence that mere adipose substance is not enough of itself to captivate the favour of the judges.

Sir Thomas Whichcote's second-prize cow is exceedingly level and handsome; her meat firm and good; but she is not well ribbed-up. Mr. Wortley's white third-prize cow is a beauty—splendidly fed.

A finer show of Herefords has never appeared at Baker-street, though their number is only three-fourths of that which we saw last week in Bingley Hall. Mr. Heath's prize steer has an immensely long frame, hip wide and well covered, tut and rump somewhat defective; altogether not so meritorious as the prize beast on some former occasions. His Royal Highness's second-prize steer is straight, deep, and heavy; but not particularly handsome. We consider Mr. Naylor's third-prize steer is of better quality; and has certainly a far better fore-quarter, though not so heavily fleshed, or so high and great. The oxen form an uncommonly good class, "generally commended" by the judges. Mr. Shaw's ox (which took the prize at Rugby, at Birmingham, and also here) is very extraordinary for his tremendous breadth, his good back and fore-quarter, and wonderfully fine head; he is very heavy, of splendid character and quality, perhaps his chief deficiency being in the flank. Mr. Heath's second-prize ox is of great length, very high standing, but not particularly good in girth. The Earl of Darnley's third-prize ox is exceedingly good; so are Mr. Ford's, Mr. Duffield's and Mr. Wright's "commended" oxen, the latter having almost a bison's depth of chest and bold fore-quarter. The heifers are a good class, Mr. Higgins' prize one being very fat and handsome, preposterous rump; Mr. Urwick's second-prize very symmetrical and compact, tut short, hips good; Mr. Thomas' perhaps too fat and lumpy.

The Hereford cows are extraordinarily good, and were all exhibited previously at Birmingham. Mr. Thomas, of Colebatch, and Mr. Thomas, of Ryton, both take prizes for uncommonly good animals. Mr. Naylor's third-prize cow is fat and of very fine quality, and Mr. Herbert's is also exceedingly good.

In the class of Devon steers we meet at once with a "bone of contention," namely the hip and rump, and other points, of His Royal Highness's second-prize steer, which, being somewhat narrow and defective, cause people to inquire how he could be selected for such an honour. His fine bone, handsome head, straight back, and nice quality of meat have been adjudged meritorious; for while the Earl of Leicester's third-prize steer has a wider fore-quarter, a better rump, thigh and twist, and good back, he has by no means that fashion about him that could make him more worthy of the second place than the other. Mr. John Overman's prize steer is a beauty; very perfect in form, a fine cylindrical frame, deep, with a full breast, and a handsome head. We also admired Mr. Fouracre's, for its size and substance. The Earl of Leicester's prize ox is very heavy, and well-fed, his girth extremely good, hind-quarters not so fine. Mr. Heath's second-prize ox has great girth, a splendid chine, but loin too lumpy, very firm in hand. Mr. Ball's third prize is a good animal; so is one shown by Mr. Fouracre, jun. His Royal Highness's is large, with a good back, beautiful breast, and most wonderful thigh and twist. Mr. Tucker's is a splendid ox; large, long, deep, symmetrical, and very weighty. The Devon heifers are an exceedingly good class. His Royal Highness's prize heifer is beautifully fed, her hips amazingly wide and good, good chine, but neck not thick enough in proportion. Mr. Farthing's second prize is very good, with a deep frame and short legs. We admired Mr. Heath's commended heifer; she is a little beauty, very fine indeed in quality. Mr. Farquharson's is extraordinarily good, particularly for her hind-quarters and rump. Mr. Coates's prize cow is very good in some points, having an especially good rump, but her first rib too much sinking-in. Mr. Bodley's second-prize cow is very handsome. Mr. Halse's third-prize cow, remarkable for her large tuts, was first at Birmingham, and at the Bath and West of England Show, and was also highly commended as a breeding cow at Chelmsford. The fact is, not only that cows are shown here which did not compete at Birmingham, but that the travelling and handling of that show greatly cut and spoil the quality of cattle exhibited here a week after, thus lessening their chance of prizes here, unless they be marvellously superior to all competitors.

The Sussex Cattle have come up well; they are better than ever: indeed, so meritorious that the whole class of steers or oxen is "generally commended." Mr. Cane's prize ox is very symmetrical indeed; of wonderful depth, and altogether a most valuable description of animal. Mr. Neame's second prize is handsome, and uncommonly good meat. We would mention, as particularly good, those shown by Mr. Botting, Mr. Shoesmith, and Mr. Jer. Smith; and among the heifers or cows, those of Mr. Tilden Smith, Mr. Neame, Mr. Cane, and Mr. Jer. Smith, are similarly worthy of great praise.

Of the Norfolk and Suffolk Polled Breeds, valuable both for fattening and for milking, we have only one in each of the two classes; but a larger show will doubtless appear next year. Lord Sondes and Mr. Badham are the successful exhibitors.

Of the Longhorns we have not much to say. Mr. Chapman's prize ox, which took the prize at Birmingham, of a light-red colour with a curly coat, is a good longhorn. Mr. Barbery's prize cow, which also obtained the prize at Birmingham, is of very good quality, though not in such good condition as she was there, and, as we were told, she would not eat "in this close place."

The Scotch Horned Steers or Oxen were "generally commended." Mr. Cheadman's prize dun-coloured Highland is of considerable merit, of extraordinary depth and substance, and stands on short legs. Mr.

Duckworth's second-prize West Highland is also very good, and another of his black West Highlands is also an uncommonly good beast. Mrs. Delap's dun West Highland, bred by Lord Abinger, has very great size; but the ribs are flat, and the frame, therefore, too narrow. The Marquis of Downshire has also a good heifer in this class. The Duke of Beaufort's light-red West Highland heifer is very good in form, and of superior quality. Mr. Naylor's, though of great proportionate length, is low, small, and not straight enough to show much symmetry.

Of the only three Scotch Polled Oxen exhibited, Mr. Heath's and Mr. M'Combie's got prizes, and Mr. Oakley's Galloway was commended. Mr. Heath's is magnificent for the breed, which is the Aberdeen; having not only great length and depth, but widely-expanded chest and fore-quarters, ribs well arched, and uncommonly good hind-quarters and rump. This is the animal which was disqualified by the French Government at Poissy, because the Scotch exhibitors protested that he had been falsely entered as pure-bred, although (as they asserted) the breeder had declared to Mr. Heath that the bullock was a cross from a shorthorn and Scot. Mr. Heath was not suffered to explain or defend himself from such a gross charge; but, owing to the interference of Mr. Fisher Hobbs, who would not quietly see his countryman treated in so underhand and unfair a manner, the documents and evidences brought forward by these protestors were obtained. A correspondence took place between Mr. Heath, Mr. Longmore the breeder, and the gentlemen who had offered their testimony to the cross breed of the ox; and this has just been published in a pamphlet, from which it would appear that the Scotch gentlemen have either retracted or been shamed to silence; while Mr. Heath has been fully cleared of the calumnious accusation made against him. At the present show he has carried off the first prize for his bullock, the judges being thoroughly satisfied about the correctness of its breed.

No Irish beasts have arrived.

In the Welsh classes every one admired Colonel Pennant's ox, which gained the first prize, and also Mr. Williamson's second-prize younger beast. Mr. Heath's black and white Welsh ox is of extraordinary size, his depth and girth being great, and his back exceedingly good.

In the cross or mixed-breed classes, the Earl of Radnor takes the first prize for a very compact and well-fed Hereford and Shorthorn steer; Colonel Towneley the second prize; and Mr. Hare's Suffolk and Shorthorn poll is a valuable animal of nice quality. Mr. Thomas's Shorthorn and Hereford ox shows the possibility of making a pretty good beast by intermixing two breeds, each of which is perfect in its own way; but we cannot say we like the produce as much as the originals. The Duke of Beaufort's prize West Highland and Devon red heifer is an interesting and successful attempt to combine the valuable qualities of amazingly distinct breeds. She is a very compactly-formed, fine, and beautiful little thing.

We do not remember to have seen such a fine Extra Stock class before; and the judges have deservedly given it a "general commendation." The silver medal is adjudicated to his Royal Highness, for a very capital Devon steer; but other judges would be quite as likely to have awarded it in a different direction. In this class we find Lord Walsingham's Shorthorn heifer, which is fat, and uncommonly good; the Marquis of Exeter's white Shorthorn ox, which took the prize at Oakham last week; the Earl of Leicester's Devon ox, handsome, fine, beautifully fed, long, yet symmetrical, slightly defective about the hind-quarters; Sir Thomas Whichcote's Shorthorn cow, level, deep-framed, and good; Mr. Brooke's enormously large Shorthorn ox; Lord Feversham's uncommonly fine, level, and beautiful Shorthorn heifer, remarkable for her wide hips and good rump of beef; Mr. Garne's good Shorthorn cow; Mr. Minton's very good and compact Shorthorn heifer; Mr. Williamson's large-horned Welsh ox, very meritorious indeed; and Mr. Pertwee's Hereford, which is a picture.

SHEEP.

There has been a considerable growth in the exhibition of good mutton, the number last year and this being as follows:

	1856.		1857.
Long-wools.....	40	..	35
Cross-breeds	18	..	32
Short-wools	38	..	62

Here we see at a glance that, while the Long-wools—or more properly the Leicesters—have slightly diminished in number, the crossbreeds and Southdowns, and other Short-wools have nearly doubled their entries in a single year. The great feature of the sheep-classes (just as at Birmingham) is the great advance made, and the size and superior quality attained, in a few years, by the crossbreeds, the long and short-wool half-breds being now some of the most profitable sheep we possess.

Class thirty-three includes some very great shearlings, as Mr. Hine's Leicester and Downs, and Mr. C. Howard's Oxfordshire Downs. It is a pity that the first prize sheep, good as they are, present the appearance of far wider backs to the eye than they actually reveal to the hand. Mr. Keep's second-prize Southdown and Cotswolds are very large, of great width and substance, thick necks, and have beautiful mutton and a good quantity of fair wool; their rumps rather defective. Mr. Hitchman's are good, and Mr. Stevens's have uncommonly good backs. Mr. John Overman's commended Southdown and Leicesters are very great, broad, and good; Mr. Edmonds's highly-commended Oxfordshire Downs not equally meritorious.

The next class — in which the sheep do not exceed 220lbs. live weight — is very good. Mr. Overman's prize Southdown and Leicesters are beauties, and their quality first-rate. Mr. C. Howard's second-prize Oxfordshire Downs are only slightly inferior; and the Earl of Leicester's, Mr. Hine's, and Mr. Twitchell's pens are all of exceeding good character.

The "Extra Stock" of crossbreds is a large class. Mr. Keep's extremely good Cotswold and Southdown wether gains the silver medal; Mr. John Overman's highly-commended Southdown and Leicester wether is very well formed, wide, and meritorious; Mr. Hine's Leicester and Down wether very handsome; Mr. Twitchell's, and the Earl of Leicester's, both deserving their commendations; and Mr. Hemming's Cotswold and Sussex Down wether is noticeable for its tremendous frame and proportions.

The short-woolled breeds are honoured with a gold medal, which has been fairly won by his Grace the Duke of Richmond, for a pen of Southdowns of his well-known character. The Earl of Radnor's Southdowns are very fine, meriting their second prize. Mr. Kent exhibits Downs of splendid form, which would have certainly gained a prize had they been more judiciously fed. The third prize is awarded to Mr. Rigden, and a high commendation to Lord Walsingham: but we do not concur in the decision here, his lordship's being much broader, better-formed, and handsomer than the others, and not far below them in quality. What a pity it is that exhibiters often leave so much to their shepherds! for were they to hand their sheep a little before sending off to the show, they would detect some two inches' thickness of wool on the shoulder and not one inch on the loin, which (we may inform them) has the effect of displaying an even, perfectly-shaped

contour to superficial observers, and by concealing a defective form from the eye, winning a favourable first impression that often goes a long way with inexperienced judges. The class for sheep under 200lbs. live weight is remarkably meritorious, and therefore "generally commended." The Duke of Richmond's prize sheep are wonderfully handsome, and of superb quality; Mr. Marjoribank's highly commended are extremely good; Lord Walsingham's beautiful, and very good mutton; Mr. Rigden's small, but very pretty, and of nice quality; but we did not like the handling of Mr. Kent's second-prize sheep anything like so well as that of some others. The Earl of Radnor's prize older sheep are of great substance, and of the right form and quality; Lord Walsingham's second prize most excellent in shape, and longer and bigger than Mr. Kent's highly-commended beautiful wethers. The Duke of Richmond is also successful here in getting the third prize. In the class for short-wools, "not being Southdowns," the first-prize Hampshire Down wethers of Mr. Sharp have good backs; of very large size, said to weigh 24 stone each. Mr. Pain gets the second prize; but the pen is not a level lot, one sheep being a beauty, and the other two having defective loins and rumps; and we are of opinion that Mr. Canning's sheep—of great size and expansion, as well as handsome looks—ought to have had this prize instead of the third. Mr. Humphries' west-country Downs are highly-commended, doubtless for their beautiful form, great substance, and splendid backs. Mr. H. Smith's Shropshire Downs, which took the prize at Birmingham, do not handle so well here as they did there, but are of very good form, with capital rumps and good wool. The extra-stock short-wool class comprises a great many sheep. The wethers are extraordinarily good; and we need only mention as of first-class character and quality the Duke of Richmond's, which won the silver medal; Mr. Kent's, highly commended; the Earl of Radnor's, highly commended; Mr. Marjoribanks, highly commended; and Mr. W. King's, commended. Mr. Foljambe's silver-medal Southdown ewe is a beauty; Lord Walsingham's and Mr. Rigden's very good.

The gold medal for long-wools is taken by Lord Berners for by far the handsomest and best shearlings in these classes. The rest of the sheep in class thirty-one do not present any very remarkable points. In class thirty, Mr. Foljambe's prize wethers are remarkably good, very good frames, handsome backs, though rumps too short. Mr. Bradshaw's second-prize pen are open to a similar criticism. Mr. Hopper's are extremely good sheep, which were commended at Birmingham. In the class for Fat wethers not Leicesters, Mr. Hewer's prize Cotswolds are particularly good; and the second-prize Cotswolds of the Royal Agricultural College of Cirencester are of great size, but rather long in frame. Lord Berners gets the silver medal in the extra-stock class for long-woolled wethers; and the Marquis of Exeter also shows well here. In the extra-stock class for ewes, Mr. Bradshaw's Leicester ewe—a real beauty, and exceedingly good in back, plaits, rump, and fore-quarters—wins the silver medal.

PIGS.

This year we have four classes of pigs instead of three, in addition to one for extra stock, the alteration providing separate competition for animals of a younger age; and, except in the last class, all the stated ages are much earlier than was formerly the case. Last year there were 25 pens of three, and 13 single animals, or 38 entries altogether: this year there are 40 pens of three, and 19 single animals, making a total of 59; which is a very large increase in one year.

Pig-breeding and pig-feeding have simultaneously progressed at such a rapid rate, that we are every year more and more astonished at the earliness of maturity they manifest. It is really wonderful how so much meat can be accumulated upon the tender, unhardened frames of mere porcine "babes and sucklings." Mr. Morland's first prize white Chiltons are not 4 months old; and Mr. Baskcomb's second prize little beauties, of the white Kent breed, are only 15 weeks old. Mr. Druce's small black Oxfordshire pigs (highly commended) are only just 3 months old. In the class for "Pigs not exceeding 8 months old," Mr. Barber's prize Middlesex pigs deserve the highest praise. Sir J. B. Mills's second-prize white pigs are very fine in quality. We admired Sir John Cathcart's black ones (highly commended), and also Mr. Crisp's 6½ months old (black), which were sucking at Salisbury in July.

The next class, for "Pigs not exceeding 12 months old," is not particularly meritorious. Sir W. Booth's white Woodburys are good, and also the pen shown by Mr. Underwood and those of Mr. Marjoribanks; and there are three pretty good Neapolitan black pigs, exhibited by Lady Pigot.

The class for "Pigs not exceeding 18 months old" is "generally commended," being certainly very magnificent.

Mr. Morland's first-prize Improved Chiltons are very perfect in form, of splendid quality, very deep, and thick both in neck, chine, and hind-quarters. Mr. Betts's second prize Improved Suffolks are also particularly good. Mr. Tombs's highly-commended black Berkshire and Essex pigs are beauties; and Mr. Sadler's Berkshires, and the Rev. J. Holmes's Norfolk and Essex pigs are remarkably good in form and quality. His Royal Highness shows some excellent pigs in this class; and there is a pen of enormously fat ones, of a black breed, from the Parkhurst Prison Farm, in the Isle of Wight.

The Extra Stock single pigs form a famous class. The silver medal is awarded to Mr. W. Davey, jun., for No. 354—small black Leicester breed, very fat, and of most beautiful quality; in symmetry uncommonly well-formed. No. 349, shown by Mr. Barber, is highly commended, having a wonderfully fat neck. No. 351, shown by Mr. Hemming, is highly commended, and is certainly of extraordinary substance. Mr. Crisp's white Suffolk sow is also highly commended—a magnificent animal, of very great size, deep, wide, and beautifully proportioned; in quality also very fine.

Taken as a whole, we do not rank the show of pigs above the exhibitions of some former years, in respect to superbness of quality and high fattening; though there are certainly several very grand specimens to be found among the unprecedented number of pens entered on this occasion.

AWARD OF PRIZES.

FAT CATTLE.

JUDGES.

S. ANSTEY, Cornwall.
J. BUCKLEY, Normanton Hill, Loughborough.
J. B. THOMPSON, Arnaby, Hull.

DEVONS.

STEERS, not exceeding 3 years old.

First prize, £25—John Overman, Burnham Sutton, Burnham Market, Norfolk. Silver Medal to breeder, Mrs. Clark, Burnham Market. Purchased by Mr. Jeffery, Foubert's-place, Regent-street.

Second, £10—His Royal Highness the Prince Consort. Purchased by Mr. Jeffery.

Third, £5—The Earl of Leicester, Holkham, Norfolk. Purchased by Mr. Jeffery.

STEERS or OXEN, above 3 years old.

First prize, £25, and Silver Medal as breeder—The Earl of Leicester. Purchased by Mr. Jeffery.

Second, £10—William Heath, Ludham Hall, Norwich. Purchased by Mr. Spencer, of Southampton.

Third, £5—Henry Hine Ball, Hankridge Farm, West Monkton, Taunton. Purchased by Mr. Harry Frampton, of Blandford, Dorset.

HEIFERS, not exceeding 4 years old.

First prize, £15—His Royal Highness the Prince Consort. Silver Medal to the breeder, James Hole, Knowle House, Dunster, Somerset. Purchased by Mr. Jeffery.

Second, £5—Walter Farthing, Stowey Court, Bridgwater. Purchased by Mr. J. W. Cowell, Colchester, Essex.

COWS, above 4 years old.

First prize, £20—John Coate, Hammoon, Blandford, Dorset. Silver medal to the breeder, Edward Boucher, Jews Farm, Wiveliscombe. Purchased by Mr. Clifton, Wimborne, Dorset.

Second, £10—John Bodley, Stockley Pomeroy, Crediton, Devon. Purchased by Mr. T. M. Smith, Westbury, Wilts.

Third, £5—John C. Halse, Molland, South Molton, Devon. Purchased by Mr. W. Stone, Holloway Road.

HEREFORDS.

STEERS, not exceeding 3 years old.

First prize, £25—William Heath, Ludham. Silver Medal to the breeder, William Stedman, Bedstone Hall, Aston-on-Clunn, Salop.

Second, £10—His Royal Highness the Prince Consort. Purchased by George Reed, Burnham, Somerset.

Third, £5—John Naylor, Leighton Hall, Welsh Pool, Montgomery.

STEERS or OXEN, above 3 years old.

First prize, £25—John Shaw, Hunsbury Hill, Northampton. Silver Medal to the breeder, Richard Shirley, Baucott, Shropshire. Purchased by George Gutheridge, High-street, Poplar.

Second, £10—William Heath, Ludham. Purchased by Mr. W. Pointing, Stroud, Gloucestershire.

Third, £5—The Earl of Darnley, Cobham Hall, Gravesend, Kent. Purchased by G. Freemantle, Upper Hill-street, Richmond, Surrey.

Commended—E. Wright, Halston, Oswestry; C. Duffield, Marcham, Abingdon; J. Ford, jun., Ruston, Blandford: and the class *generally commended*.

HEIFERS, not exceeding 4 years.

First prize, £15—Henry Higgins, Woolaston Grange, Lydney, Gloucester. Silver Medal to the breeder, William Raester, Withington Court, Hereford.

Second, £5—Samuel Walker Urwick, Linthall Starks, Ludlow.

COWS, above 4 years old.

First prize, £20, and Silver Medal as breeder—Edward Thomas, Colebatch, Bishop's Castle, Salop.

Second, £10—Richard Thomas, Ryton, Dorrington, Salop. Purchased by Mr. Tomline, 2, Queen-street, Pimlico.

Third, £25—John Naylor, Leighton. Purchased by Mr. G. Stanley, 10, Cambridge Road, Mile-End Gate.

SHORTHORNS.

STEERS, not exceeding 3 years old.

First prize, £25, and Silver Medal as breeder—Robert Lynn, Stroxton, Grantham, Lincoln. Purchased by W. Bottrell, Rochester-row, Westminster.

Second, £10—Earl Spencer, Althorp, Northampton. Purchased by W. Lambert, Victoria-road, Pimlico.

Third, £5—Joseph Stratton, Manningford Bruce, Pewsey, Wilts. Purchased by Smith and Son, Salisbury.

STEERS or OXEN, above 3 years old.

First prize, £25, GOLD MEDAL as best steer or ox in any of the classes, and Silver Medal as breeder.—Edward Wortley, Ridlington, Uppingham, Rutland. Purchased by Messrs. Davis, Black Bull, New Cattle Market.

Second, £10—W. de Capell Brooke, Geddington Grange, Kettering. Purchased by W. Jones, Merthyr, Glamorganshire.

Third, £5—Henry Roberts, Paxford, Moreton-in-Marsh, Gloucester.

Commended—Lord Southampton, Whittlebury, Towcester.

HEIFERS, not exceeding 4 years old.

First prize, £15—Joseph Phillips, Ardington, Wantage, Berks. Silver Medal to the breeder, Richard Stratton, Broad Hinton, Swindon. Purchased by Thomas Collingwood, Abingdon, Berks.

Second, £5—Earl of Radnor, Coleshill House, Faringdon, Berks. Purchased by William Jones, Merthyr.

COWS, above 4 years old.

First prize, £20, GOLD MEDAL as best cow or heifer in any of the classes, and Silver Medal as breeder—Lieut.-Col. Charles Towneley, Towneley, Burnley, Lancaster.

Second, £10 — Sir Thomas Whichcote, Bart.. Ashwarby Park, Falkingham, Lincoln.

Third, £5 — Edward Wortley, Ridlington, Purchased by Mr. Thomas Phelp, 10, Seymour-place, Camden Town.

Commended—T. Garne, Broadmoor, Nothleach.

SUSSEX.

STEERS or OXEN of any age.

First prize, £20, and Silver Medal as breeder—Edward Cane, Berwick Court, Lewes. Purchased by Mr. Sharp, Brighton.

Second, £10—Charles Neame and Sons, Selling, Feversham, Kent. Purchased by Mr. Sharp.

The Class *generally commended*.

HEIFERS or COWS of any age.

First prize, £10, and Silver Medal as breeder—Tilden Smith, Beckley, Staplehurst, Sussex. Purchased by Mr. Spinger, Southampton.

Second, £5—Charles Neame and Sons, Selling, Feversham, Kent.

Commended—E. Cane, Berwick.

NORFOLK or SUFFOLK.

POLLED STEERS or OXEN of any age.

First prize, £10, and Silver Medal as breeder — Lord Sondes, Elmham Hall, Thetford, Norfolk. Purchased by Mr. G. Nicholson, North Elmham, Norfolk.

POLLED HEIFERS or COW, of any age.

First prize, £10, and Silver Medal as breeder—G. D. Badham, The Sparrow's Nest, Ipswich. Purchased by Mr. T. Richards, 3, Phœnix-street, Somers Town.

LONGHORNS.

STEERS or OXEN, of any age.

First prize, £10—R. H. Chapman, Upton, Nuneaton, Warwick. Silver Medal to the breeder, the late Samuel Burbery, Wroxhall, Warwick. Purchased by Mr. Newbury, Southampton-street, Camberwell.

HEIFERS or COWS, of any age.

First prize, £10—Joseph Holland Burbery, of The Chase, Kenilworth, Warwick. Silver Medal to the breeder, the late Samuel Burbery, Wroxhall. Purchased by Mr. Newbury, Southampton-street, Camberwell.

Second, £5—John Jackson Burbery, Ibstock, Ashby-de-la-Zouch, Leicester. Purchased by Mr. Newbury.

SCOTCH-HORNED.

STEERS or OXEN, of any age.

First prize, £20—Mr. Alexander Goodman, Willow Hall, Thorney, Cambridge. Purchased by Mr. Smith, King's-road, Chelsea.

Second, £10—Mr. Thomas Duckworth, Park Farm, Finchley, Middlesex. Purchased by Mr. James Horne, High-street, Camden Town.

The class *generally commended*.

HEIFERS or COWS, of any age.

First prize, £10, and Silver Medal as breeder—The Duke of Beaufort, Badmington, Chippenham, Wilts. Purchased by Mr. Thomas Pawsey, Bath.

Second, £5—Mr. John Naylor, Leighton. Purchased by Mr. H. Squire, Watford, Herts.

SCOTCH POLLED.

STEERS or OXEN, of any age.

First prize, £20—Mr. William Heath, Ludham. Purchased by Mr. S. Mann, Croydon.

Second, £10—Mr. William McCombie, Tillyfour, Aberdeen. Purchased by Mr. Joseph Bannister, Windsor.
Commended—Mr. R. Oakley, Laurence End, Luton.

HEIFERS or COWS, of any age.
[No entry.]

IRISH.

STEERS OR OXEN, of any age.
[No entry.]

HEIFERS OR COWS, of any age.
[No competition.].

WELSH.

STEERS or OXEN (Runts), of any age.

First prize, £20—The Hon. Colonel Pennant, Penrhyn Castle, Bangor, Carnarvon—Silver Medal to the breeder, Mr. Richard Evans, Tal-y-braich, Bangor. Purchased by Hall and Son, Liverpool.
Second, £5—Mr. Isaac Williamson, Greenhill, Pembroke. Purchased by Mr. Petherbridge, Hastings-street, Brunswick-square.
The class *generally commended*.

HEIFERS or COWS, of any age.

The prize of £10—Mr. John Ewins Bennett, Bosworth Grange, Rugby. Purchased by Mr. G. Hatch, Croydon.

CROSS OR MIXED-BRED.

STEERS, not exceeding 3 years old.

First prize, £15, and Silver Medal as breeder—The Earl of Radnor, Coleshill House, Faringdon. Purchased by Mr. Field Waghorn, Cheltenham.
Second, £10—Lieutenant-Colonel Charles Towneley. Purchased by Miss Abbott, Wimborne.

STEERS or OXEN, above 3 years old.

First prize, £15—Mr. Richard Thomas, Ryton, Dorrington, Salop—Silver Medal to breeder, Mr. J. K. Smith, Radbrook, Shrewsbury.
Second, £5 — Henry Bone, Avon Farm, Ringwood, Southampton. Purchased by Mr. John Ridout, Poole, Dorset.

HEIFERS, not exceeding 4 years old.

The prize of £10, and Silver Medal as breeder—The Duke of Beaufort. Purchased by Mr. Thomas Pawsey, Bath.

SHEEP.

JUDGES.

S. ANSTEY, Cornwall.
J. BUCKLEY, Normanton Hill, Loughborough.
J. B. THOMPSON, Arnaby, Hull.

FAT WETHER SHEEP, of ANY LONG-WOOLLED BREED, 1 year old (under 22 months.)

First prize, £20, and Silver Medal as breeder—Mr. G. S. Foljambe, Osberton Hall, Worksop, Notts. Purchased by Mr. Newbury, Southampton-street, Camberwell.
Second, £15—Mr. C. J. Bradshaw, Alstoe House, Burley-on-the-Hill, Oakham, Rutland. Purchased by Mr. Wm. Hawkins, 6, Johnson-place, Harrow-road.
Third, £5—Mr. John Hopper, Brompton Green, Pickering, York. Purchased by Mr. E. Bassett, Crown-court, St. James's.

FAT WETHER SHEEP, of any long-woolled breed, 1 year old (under 22 months), each sheep not to exceed 220lbs. live weight.

First prize, £20, GOLD MEDAL as best long-woolled sheep in any of the classes, and Silver Medal as breeder—Lord Berners, Keythorpe Hall, Leicester. Purchased by Alfred Gorton, Great Windmill-street, Haymarket.
Second prize, £15—Richard Newman, Harrowden, Bedford. Purchased by Mr. J. Parfitt, Old Manor-road, Stepney.
Third prize, £5—G. S. Foljambe, Osberton.

FAT WETHER SHEEP, of any long-woolled breed not Leicestera, 1 year old (under 22 months).

First prize, £15, and Silver Medal as breeder—William Hewer, Seveuhampton, Highworth, Wilts. Purchased by Mr. Samuel Bridge, Manor-street, Chelsea.
Second prize, £10—The Royal Agricultural College, Cirencester. Purchased by Mr. Rebble, Chapel-street, Edgeware-road.
Third prize, £5—*no competition*.

JUDGES for cross-bred and short-woolled sheep—
J. CLAYDEN, Littlebury, Saffron Walden.
H. LUGAR, Hengrave, Bury St. Edmunds.
E. POPE, Great Toller, Dorset.

LONG AND SHORT-WOOLLED CROSS-BRED FAT WETHER SHEEP, 1 year old (under 22 months).

First prize, £15, and Silver Medal as breeder—George Hine, jun., Oakley, Bedford. Purchased by Mr. Spinger, Southampton.
Second prize, £10—Adam Corrie Keep, Wollaston, Wellingborough. Purchased by Mr. Worley, Kensington.
Third prize, £5—Charles Howard, Biddenham, Bedford. Purchased by Mr. S. Knight, Union-street, Clarendon-square, Somerstown.
Highly commended—E. Edmonds, Longworth, Faringdon.
Commended—J. Overman, Burnham Sutton.

LONG AND SHORT-WOOLLED CROSS-BRED FAT WETHER SHEEP, 1 year old (under 22 months), each sheep not to exceed 220lbs. live weight.

First prize, £10, and Silver Medal as breeder—John Overman, Burnham Sutton. Purchased by Mr. Sacks, Crawford-street, Marylebone.
Second prize, £5—Charles Howard, Biddenham. Purchased by John Stevens, Oxford.
Highly commended—The Earl of Leicester.
Commended—G. Hine, jun., Oakley.

FAT WETHER SHEEP, of any short-woolled breed, 1 year old (under 22 months).

First prize, £20, GOLD MEDAL as best short-woolled sheep, and Silver Medal as breeder—The Duke of Richmond, Goodwood, Chichester. Purchased by Mr. King, Paddington-street.
Second prize, £10—The Earl of Radnor, Coleshill House, Faringdon. Purchased by Mr. Stimpson, Wandsworth.
Third prize, £5—William Rigden, Hove, Brighton. Purchased by Mr. Davey, Brighton.
Highly commended—Lord Walsingham, Merton, Thetford.

FAT WETHER SHEEP, of any short-woolled breed, 1 year old (under 22 months), each sheep not to exceed 200lbs. live weight.

First prize, £10, and Silver Medal as breeder—The Duke of Richmond. Purchased by Mr. King, Paddington-street.
Second prize, £5—John Kent, Goodwood, Chichester. Purchased by John Stevens, Oxford.
Highly commended—S. Marjoribanks, Bushey Grove, Watford.
Commended—Lord Chichester, Stanmer, Lewes; and the class *generally commended*.

FAT WETHER SHEEP, of any short-woolled breed, 2 years old (above 22 and under 34 months).

First prize, £20, and Silver Medal as breeder—The Earl of Radnor, Coleshill. Purchased by W. Jeffery, Foubert's-place.
Second prize, £10—Lord Walsingham, Merton Hall, Thetford. Purchased by W. Jeffery.
Third prize, £5—The Duke of Richmond. Purchased by W. King, Paddington-street.
Highly commended—J. Kent, Goodwood.
Commended—W. Rigden, Hove.

FAT WETHER SHEEP, of any short-woolled breed not South Downs, 1 year old (under 22 months).

First prize, £15—James Sharp, Remenham, Henley on Thames; Silver Medal to the breeder, John Piggott, Harrow Farm, Froxfield, Hungerford. Purchased by W. Jeffery.
Second prize, £10—J. T. F. Pain, North Houghton Manor, Stockbridge. Purchased by Alfred Gorton, Great Windmill-street, Regent-street.
Third prize, £5—William B. Canning, Chisleden, Swindon, Wilts. Purchased by W. Bottrill, Rochester-row, Westminster.
Highly commended—W. Humphrey, Oak Ash, Wantage.
Commended—W. King, New Hayward, Hungerford.

PIGS.

JUDGES.

J. CLAYDEN, Littlebury, Saffron Walden.
H. LUGAR, Hengrave, Bury St. Edmunds.
E. POPE, Great Toller, Dorset.

PIGS of any breed, not exceeding 4 months old.

First prize, £10, and Gold and Silver Medals as breeder—George B. Morland, Chilton Farm, Abingdon, Berks. Purchased by John Lewes, Bristol.

Second, £5—George Henry Bascomb, Manor House, Chislehurst, Kent. Purchased by Mr. Ketteman, King-street, Bow.

Highly commended—S. Druce, Eynsham, Oxon.

PIGS of any breed, above 4 and not exceeding 8 months old.

First prize, £10, and Silver Medal as breeder—William Mills Barber, Sunninghill Wells, Berks.

Second, £5—Sir J. B. Mill, Bart., Mottisfont Abbey, Romsey, Southampton. Purchased by Mr. Benny, Camberwell Gate.

Highly commended—Sir J. A. Cathcart, Cooper's Hill, Chertsey.

Commended—T. Crisp, Butley, Woodbridge.

PIGS of any breed, above 8 and not exceeding 12 months old.

First prize, £10—Sir Williamson Booth, Bart., Woodbury Hall, St. Neots. Purchased by Mr. G. Glock, Broadway, Deptford.

Highly commended—G. Underwood, Ashbridge, Berkhampsted.

Commended—S. Marjoribanks, Bushey Grove.

PIGS of any breed, above 12 and under 18 months old.

First prize, £10, and Silver Medal as breeder—George B. Morland, Chilton. Purchased by Mr. Tinkler, Knightsbridge.

Second, £5—Edward Ladd Betts, Preston Hall, Maidstone. Purchased by Mr. John Lewes, Bristol.

Highly commended—J. K. Tombs, Langford, Lechlade.

The class *generally commended*.

EXTRA STOCK.

Silver Medal, for the best Beast in extra stock—His Royal Highness the Prince Consort (Devon Steer). Purchased by Messrs. Comfort and Son, 77, Farringdon-street, City.

Silver Medal, for the best Long-woolled Wether Sheep in extra stock—Lord Berners. Purchased by Alfred Gorton, Great Windmill-street, Haymarket.

Silver Medal, for the best Long-woolled Ewe in extra stock—Mr. C. J. Bradshaw, Alstoe, Burley-on-the-Hill. Purchased by Mr. Ford, Kenton-street, Brunswick-square.

Silver Medal, for the best Cross-bred Sheep in extra stock—Mr. Adam Corrie Keep, Wollaston, Wellingborough (Southdown and Cotswold).

Silver Medal, for the best Short-woolled Wether Sheep in extra stock—The Duke of Richmond. Purchased by Mr. King, Paddington-street.

Silver Medal, for the best Short-woolled Ewe in extra stock—Mr. G. S. Foljambe. Purchased by Mr. Turpen, Barking, Essex.

Silver Medal, for the best Pig in extra stock—Mr. William Davey, jun. (Leicester.)

The Cattle in extra stock *generally commended*.

In extra-stock Sheep, *highly commended*—Mr. J. Overman, Burnham (Southdown and Leicester), Mr. J. Kent (Southdown), Mr. S Marjoribanks (Southdown), Lord Radnor (Southdown), and Lord Walsingham (Southdown).

In extra-stock Sheep, *commended*—Lord Leicester (Leicester and Southdown), Mr. J. B. Twitchell, Wilby (Down Cotswold and Leicester), Mr. W. King (West-country Down), and Mr. W. Rigden (Southdown).

In extra-stock Pigs, *highly commended*—Mr. W. Mills Barber, Sunning-hill (Improved Middlesex), Mr. W. Hemming, Coldicott, Moreton-in-Marsh (Improved Coldicott), and T. Crisp, Butley (Suffolk).

EXHIBITION OF IMPLEMENTS, ROOTS, &c.

We will certainly try to give some report of this exhibition, but the crowded state of the galleries containing the specimens exhibited forbids any approach to accuracy in detail; and much as we should like to oblige our many exhibitors by an extended notice of their interesting collection of implements, machinery, articles of dairy and domestic use, and the various root, seed, and other stalls, we find it is utterly impossible to do so with any satisfaction to ourselves or to them. If want of space characterizes the cattle show below, how much more is it felt above! There valuable implements are packed one above another, and others are never seen at all. We inquired for Bentall's well-known scarifier, and, large as it is, it was hidden amongst the surrounding implements. This department of the Smithfield Club Show is now becoming a most important feature; the immense offshoot is fast outgrowing the stupendous tree, and must be provided for. We are well aware that the implement show is independent of the Smithfield Club, and forms no part of their operations; but as it has now become in *real fact* a prominent part of the show, the public look to the Club to make provision for suitable accommodation. Last year the charge for space was one guinea for every 4ft. 6in. frontage; this year the same charge is made for 2ft. 9in. frontage. We were told that one of our leading firms paid from £33 to £37 for standing, another a similar sum, another £22, and so on according to the engaged space. We do not know the area of these galleries, but they contain about 100 exhibitors, few of whom pay less than from two to ten guineas each. We never heard a complaint so general of bad accommodation, for which they paid so dearly. The proprietor has done what he could to divide his space between the applicants; but not having enough, the consequence is that the implements and machinery are imperfectly shown, they thus obtain a doubtful reputation, and dissatisfaction is the result. We commend the subject to the Smithfield Club. Something must be done. The proprietor must be induced to enlarge his space by adding more upper galleries, and the steam-engines below must give place to the stock. We admire the general arrangements made by Mr. Boulnois for the accommodation of all parties, and we think the site of the show-yard very desirable; but as the thing continues to grow, the space will not suffice, and it will ultimately be for the Club to provide for its increasing exhibitors. We think the neighbourhood of the Metropolitan Market could point out a good place. We have now every convenience of rail and other modes of transit. It may not be visited by so many of the London citizens as a *show place;* but the attendance of agriculturists would be larger, as it would undoubtedly then include the Great Metropolitan Market-day, when great numbers from every part of the kingdom attend. It is precisely at this period of the year when a national implement show is of most value: the various operations of thrashing, chaff cutting, cake-breaking, root-steaming, &c., are now going on, and farmers are not always so provident as to provide these things in the summer for the requirements of the winter. We urge these matters upon the favourable attention of the Club.

We will now elbow our way through the rows of machinery. The usual place below-stairs was appropriated to the exhibition of steam-engines and thrashing-machines, but so pressed have the club been for room, that they could not allow any firm to show both an engine and machine; so that Messrs. Garrett and Sons, Clayton and Shuttleworth, Barrett and Exall, Tuxford and Sons, Ransomes and Sims, Oliver Maggs, and Hayward (of Derby) exhibited their well-known portable engines; whilst Hornsby and Sons, Wedlake and Dendy, Humphries, Roby and Scott, Foord (of Lenham), and Smith and Co. preferred showing their combined thrashing and dressing or finishing machines. Holmes and Son (Norwich) had also their cloverseed-drawing machine; and Heywood's two-and-a-half-horse engine,

with vertical cylinder and novel method of working the slide, is well worthy the attention of the farmer.

[We now ascend the stairs with the crowd, for the short time permitted for the private view does not suffice to allow us to obtain even a cursory look at the implements. This might be obviated another year without interfering with the stock judges. We commend this to the stewards·]

We make our way to No. 1, the stall of our indefatigable Director, or rather the firm with which he stands connected. They exhibit a splendid collection of roots—globe mangolds in abundance, weighing from 20 to 31½lbs. each; carrots, reds and whites; exceedingly good long red mangolds, very fine specimens; capital swedes, Mr. Rose's variety standing prominent; many beautiful specimens of turnips in great variety. Many of the roots have the names of the growers ticketed upon them; amongst whom we observed his Royal Highness the Prince Consort, the Duke of Bedford, Mr. W. F. Hobbs, Mr. Powells, Mr. Druce, Mr. Williams, Mr. Fryer, Mr. W. E. Williams, Rev. R. T. Forrester, Mr. J. Arkwright, Mr. J. B. Twitchell, Mr. B. Crawshay, Mr. F. Strickland, and the Parkhurst Prison Spade Husbandry. The stall was beautifully ornamented with specimens of seeds and grasses, &c.

The next stand is Mr. Busby's, of Bedale, York, who exhibits his very useful prize carts and ploughs, Woofe's patent paring-plough, and horse-hoes.

Wedlake sent a two-horse and a three-horse steam machine of very useful character. These small machines and engines appear to make way; we have this year several exhibitors of them.

Messrs. Garrett and Sons have the next stand, and display their usual admirable selection from their manufactory. Their horse-hoe has a new and novel appliance for elevating and depressing the hoes in work, consisting of a movement made by a right and left-handed screw, which, as turned by a crank, will lower or elevate the hoes as required. To names so well known as improvers in agricultural mechanics we need not add our word of approval.

Messrs. Geo. Gibbs and Co. show a stall of unusual interest: cabbages weighing 30lbs., gourd 125lbs., grown by Messrs. Thraill; Skirving's swedes, very large; stubble or River's swede, grown since 1st of August; these and the yellow mangolds, very fine.

Biggs' dipping apparatus comes next. The sheep in trough looks natural, and attractive enough to the casual visitor.

Clayton and Shuttleworth are exhibitors of their excellent machinery. The chief thing we would notice in connection with this firm is their general reduction in prices of their engines and thrashing-machines, drying from five to fifteen per cent., as good as ever.

Clayton (Henry) brings a very interesting model of a cottage built with his improved bricks, tubular and perforated. The cottage model is exceedingly good, and consists of a double cottage under a large, expanding roof, the one cottage being behind the other: a small portico entrance, living room to the right, boys' bed-room to the left, stairs in front of door; the upper floor consists of parents' bed-room and girls' bed-room, with closets, &c.; the living-room 11 feet 4 inches by 9 feet 4 inches, other details in proportion; the price of double cottage, £150. They have brought out also a hand-machine for brick-making, and a small two-horse pugging and brick machine; their machines for brick-making are so well known, that it is almost superfluous to enumerate them.

Jno. Warner and Sons have a stand of their celebrated pumps for field service and the fold-yard; root-cutters and graters. Their irrigating pump may become a valuable acquisition in farm management.

T. Lloyd and Sons enter their superior flour and corn crushing mills. These flour mills divide the meal into five parts. We found Ball's ovens here.

Sutton and Sons have a splendid show of roots. Globe yellow mangolds, very large: one grown on the Prince Consort's farm weighed 29lbs.; another by Earl Radnor 31½lbs., which took the prize at Cirencester; a long white mangold weighed 42lbs., another 40lbs.; some large long reds by Mr. Benyon. Turnips and other roots in splendid variety.

Jas. and Fred. Howard exhibit their famed ploughs, horse-rakes, &c. They have effected an improvement in strengthening their plough-beams by manufacturing them of "ribbed or T iron," taking care to give additional strength at the point of draught. When this is done, the weight of the plough is not so heavy by 6lbs. The coulter-stalk is oval. The management of wheel fastenings is new and commendable.

Burgess and Key have an interesting exhibition, attracting much attention, their prize reaper ranking first: the conical screw, aiding so admirably the side-delivery, was much noticed. The machine looks somewhat large and massive, but we have the result of the trials at Boxted Lodge showing the draught before us, which we have pleasure in giving. It is as follows:

Messrs. Burgess and Keys's. 2¾ cwt., cutting 5 ft. 4 in.
Messrs. Crosskill's Bell . . . 4 cwt., cutting 5 ft. 4 in.
Messrs. Dray and Co.'s . . . . 3 cwt., cutting 4 ft. 4 in.

Their rotary pump is a novelty worth close examination: it is a peculiar way of raising water, the continuous turning of the crank causing a constant flow of water through the vulcanized india-rubber pipe; it is effected by pressure creating the vacuum.

Dray and Co. have a first-class collection, including their prize reaper, which created such interest at Waterford. Their other implements fully sustained their acknowledged reputation as first-class mechanics as well as agents. Their portable forge is a simple and useful appendage in a farm-yard.

Messrs. Priest and Woolnough attract us with their first-class horse-hoe, Garretts' pattern, with their own improvements, the elevating and depressing movement being the chief. Their general-purpose drills do the firm great credit for clever arrangement, workmanship, and cheapness.

Bentall has no less than three stands in different places of the gallery, owing to want of space for convenient showing. He has a first-rate collection of his own manufacture: his root-pulper now forestalling his celebrated scarifier, in public interest. We did not observe anything new as coming out since the Salisbury Meeting. That it is to novelties that throughout this report we have confined ourselves, having at that time entered pretty fully into a notice of all the known improvements.

E. R. and F. Turner exhibit their customary and excellent assortment of agricultural machinery, consisting of roller mills, crushing and grinding mills, cake-breaker, chaff-cutter, circular-saw bench, &c., &c.

Hornsby and Sons—Their unrivalled drills and dressing machines, so universally known as to barely need our notice of them as being present here.

Lawson and Son, select specimens of wheat, oats, roots, &c.: their Lothian purple top continues to give great satisfaction, being a near approach to the firm flesh of the swede. Their Tweeddale yellow and Kohl rabi are very fine roots. The stall was a fine exhibition of roots of Scotch growth.

Skirving's stall is as attractive as ever—some immense swedes and carrots. The swedes retain their character in shape, quality, and size, and are now become quite a known sort everywhere.

BINNS' manures deserve notice. He shows a sample of wool manure.

BARRETT and EXALL'S stand commands attention by a large display of medals. But this is not all; their show of implements and machinery is very superior, consisting of a good assortment of their excellent manufacture. We think their names so well known that we need not add more.

ANGEL and Co. make a selection of agricultural books and almanacks. They appear desirous to aid in agricultural literature by a choice selection.

CROSSKILL and Co.—This, again, is a firm so well known, and the implements and machinery they exhibit are so highly appreciated, that it seems to us quite out of place to do more than notice them otherwise than in this general way: all was as is usual with them.

THORLEY called attention to his stand of samples of flour for cattle food by the display of a magnificent gold cup, which he is desirous to present to the Royal Agricultural Society for their gift to the farmer who shall fatten the most cattle best from his prepared food.

ARCHER brings forward some useful nose pincers or cattle leaders, at 2s. 6d. each.

TREE and Co. show Ewart's cattle gauges, and Casella's weather instruments.

GROVE (JAMES) has his usual good collection of roots; his long red Bugle mangels are excellent; turnips, &c., in good variety. We are pleased to see him keep up so good a stock.

RICHMOND and CHANDLER take their usual prominent position in the exhibition gallery; amongst their machinery and implements we noticed a very useful and cheap chaff-engine for small occupations, price £3 15s.

SNOWDEN (W.) exhibits a chaff engine and bruising mill. The chaff engine has a large feeding-box, and is a large machine to be worked by one person; it does not feed by rollers, but by a web underneath; the feed "only comes forward when the knife is from it;" its novelty deserves attention.

HOLMES and SONS send their manure-distributor, drill, and other machinery and implements; their weighing machines have long stood high in public favour: they have also chaff engines, corn crushers, cake breakers, turnip cutters, and pig troughs in good variety; their corn-dressing machine is popular.

MOORE and Co. have churns in variety; the Yankee churn the chief attraction. We did not see the Yankee reaper.

SWIFT Brothers show their patent washing, wringing, and mangling machines, liquid-manure pump, corn bin, &c.; all very good.

CULLINGFORD (W.) boasts of very excellent garden netting, sheep-fold netting, rabbit nets, carriage-horse nets, fishing-nets, &c., some from cocoa fibre.

PAGE and Co. had a capital root-stall, immense cabbage, mangels, and turnips; six of Skirving's improved weighed 110lbs., and six mangels weighed 193lbs.; the largest specimen of mangel we noticed was on this stand, its weight 44lbs.; turnips in fine variety.

BARNARD and BISHOP have their celebrated root pulpers in variety.

SELBY HAND, a combined crushing mill, sack weighing machine and lifter.

PICKSLEY, SIMS, and Co.: Chaff cutters, mills, washing machines, chain harrow, lawn mower, and wringing and mangling machine.

GODDARD: A very complete kitchen range.

B. FOWLER and Co.: Cast-iron and bored pumps, wrought-iron pumps, liquid-manure pumps on tripod stands, and iron stable pails. These pumps last year obtained great attention from their double action, thus keeping up a continuous flow of water; "the piston is solid, and all the valves being out of the barrel, permits their areas to equal that of the piston, and the water passages to be proportionately large;" the arrangements of the details are very good, the application of Holman's patent reciprocating lever being an improvement.

JAMES exhibited his liquid-manure carts.

T. HUNT and Brothers: A clover and trefoil seed drawer, chaff engine, scythes, and a variety of other useful farm machinery; well worthy a better notice.

SIGMA: Dibbling implements, &c.; specimens of wheat unusually fine.

CARSONS'S chaff cutters, scarifiers, mills, crushers, pulpers, hay rakes, ploughs, &c., stand deservedly high in public estimation.

IMPEY shows his well-known dressing machine.

SMITH and SONS, their truly-valuable drills, of simple construction and excellent manufacture; we believe this firm is the oldest in drill machinery extant.

CAMBRIDGE sends his chain harrows; we suppose the regulations relative to weight (not to exceed one ton) would preclude the exhibition of his large rollers.

SAMUELSON showed his Gardner's turnip cutter in variety, as also several pulpers, corn crushers, chaff cutters, pumps for irrigation, and foldyard washing machines, and a variety of other useful articles, in character with his long-established reputation for first-class machinery.

WILLIAMS' celebrated harrows were among other things exhibited of highly useful character.

REEVES.—In addition to his celebrated Chandler's liquid manure drills, which he has improved by an alteration of the speed of delivery, showed a garden or one-row drill. This can be made to deposit seed continuously or as a drop or "bunch" drill; the regulation is by discs with perforated holes of various sizes inserted in the upright cylinder containing the seed; these are turned as the drill proceeds, and the seed drops through. The height is regulated by the diameter of the wheel, but it is requisite that the dropping should be close to the soil for "bunching." Price £3 10s. A new invention by Mr. Reeve.

WOODS exhibited a section of his poppy extirpator, pulper, and other useful articles.

DELF entered a new invention for opening furrows, or rather for taking the sheep droppings with the furrow sole out of furrows on seed pastures, and distributing them over the surface. It is of similar form to Bentall's scarifier—say with one share on—and it has two long iron plates four or five feet by six inches, which expand and throw soil and manure over the surface. I is novel, but did not appear to us a very useful implet ment for its price, £10 10s.

WARREN'S expanding plough we heard was here, but we did not see it.

LUCK'S dressing machine with patent elevators for weighing, together with his mills, constituted his standing. The dressing machine is very popular.

FISHER exhibited his very useful horse-rake, mounted on his other implements for want of space. His cake mill is cheap; and his other exhibition consisted of bean, oats, and barley mills, chaff engines, &c.

PURDIE and Co. brought washing machines and knife cleaners. The washing machine is an oblong chest, with dashers.

READ'S cattle probangs, &c., and garden engine came next in our walk.

SMITH and ASHBY exhibited a well-known assortment of their most useful implements; the latest improvements in their chaff-engines, being a newly-invented patent safety presser: this is a lifting roller immediately behind the cutting front, which prevents clogging. Their chief novelty in this show is a 2½ horse power steam engine, which can be used to work machinery, or is easily converted into a steaming apparatus by turning the steam into steam cylinders or tubs; price £60.

WALLIS and HASLAM have a good selection of implements; their two-horse portable thrashing machine is good for small occupations.

WHITMEE.—His flour mills, crushing mills, &c.

BOBY'S Screen.—This screen has received an improvement; it will now separate into three distinct qualities. It has an additional separator like a flat box, fixed in front, and receives beans, peas, &c., which it deposits by spouts behind.

BARTON'S stable fittings are very complete throughout; his self-acting rack keeps the hay always within reach of the horse, by the elevation of the bottom, like as sash windows are raised.

BOYD'S dairy and washing utensils are worth a closer inspection; he also shows a variety of implements.

BRIDGES has an almost infinite collection of butter prints, of very pretty devices suited to the purpose.

BURNEY and BELLAMY have iron cisterns of various sizes.

THE ST. PANCRAS WORKS show varieties in mangers, stable fittings, and furniture, specimens of wire and iron fencing, hurdles, field-gates, and wire netting.

JAS. HAYES.—Grinding mill, straw elevator pattern, &c.

S. SKYE AND CO.—Coffee-mills, sausage mills.

PERREAUX'S patent pump is a capital general purpose pump, and its india-rubber piston-valve has proved well under severe trial.

WHITEHEAD shows his very superior brick and tile machines, which have received many honours from our different societies at home and abroad. His pug machine is exceedingly good.

THOMPSON'S haymaking machine and horserake—two very superior implements, of which we reported favourably in our Salisbury report.

COLEMAN displays his Hanson's prize potato digger, his scarifier or cultivator, harrows, &c. Hanson's potato digger is *the* implement of the year: its capabilities are great—it will clean a ridge of potatoes without difficulty, throwing them abroad for picking so that all can be readily gathered. It has been more than once described in the *Mark Lane Express*. "Coleman's cultivator" is assuming a new position. He has succeeded in adapting it on a large scale for steam cultivation. Its adaptation was fully proved at the great meetings of Salisbury and York, where it was worked by Boydell's traction engine.

CROWLEY and SON show a truly well-made and very useful cart, the wheels run on bevel tire or square level soles. Tipping apparatus very good.

OLIVER MAGGS exhibits a good assortment of machinery. Chaff engines, cake breakers, turnip cutters, bean and other mills and crushers, &c., &c.

SMITH'S steerage horse hoe is the best of its kind, and after Goorka pattern. Delving machine good.

WHEELER sent his patent root grater, turnip cutter, circular saw, and bean mill. The circular saw is a very useful machine.

COTTAM and HALLEN have an attractive stand, consisting partly of stable fittings, in variety of racks and mangers. Their new triangular manger, for corners, is a very convenient one. We noticed a good and unique corn-bin of sheet-iron. Their stable furniture, containing every requisite, is excellent. They make a small portable liquid manure pump to run on its own wheels, the pipe of vulcanized India-rubber. It is of very simple arrangement; can be moved to any cesspool for emptying it, &c.

HALIFAX and Co. display their farmers' account books, recommended by the Royal Agricultural Society of England, containing five books, *i. e.* for weekly transactions—sale, purchase, ledger, and cash respectively.

RANSOMES AND SIMS occupy the most extensive stand in the gallery, consisting of ploughs in great variety, chaff engines, cake-breakers, crushing mills for every farm purpose, with other machinery of their almost unrivalled manufacture. We did not observe any new invention or recent improvement of moment; while to give here any extended notice to describe the uses and exquisite finish of *their* implements and machinery, would indeed be superfluous.

THE ROYAL DUBLIN SOCIETY'S EXHIBITION.—The efforts of this Society have done much for Ireland. It was established so far back as 1731. It now enjoys a Government grant of £7,000 annually, besides annual subscriptions amounting to £2,000. An entrance fee of £20 with an annual subscription of £1 1s. constitutes an honorary member, and an entrance fee of £5 5s. with an annual subscription of £1 1s. an annual member. The specimens on the Society's stands were a portion of those shown at the Society's winter exhibition of farm and dairy produce, held last month on their premises in Dublin. The several roots, and samples of cereals, pulse, wool, and butter, were principally contributed by the following noblemen and gentlemen: the Duke of Leinster, the Earl of Charlemont, Col. Kane Bunbury, the Marquis of Waterford, Major Quentin, Doctor Taylor, Doctor Collins, the Commissioners of the Board of National Education in Ireland from the Albert Model Farm and several of their district model farms, J. H. Peart, Doctor Radcliffe, LL.D., J. E. V. Vernon, Lord Talbot de Malahide, the Marquis of Kildare, &c., &c. The Royal Dublin Society exhibited, for the first time, collections of Irish-grown produce at the Smithfield Club Show in 1851, at the request of the Earl of Clarendon, then Lord-Lieutenant of Ireland, and, by virtue of his office, President for the time being of the Society. The good results which attended that step are well known in Ireland and in this country. The collection shown at the Smithfield Club Show during 1851 and the subsequent years brought before the British capitalist the capability of the soil of Ireland for the production of white and green crops, "the great reproducers of beef;" and English capital, still further stimulated by the Great Irish Exhibition of 1853, flowed freely into Ireland, and was largely employed in land speculations, which turned out to be of a permanent and highly remunerative kind. The Council of the Society have sent forward this year a collection of excellent farm products from various parts of Ireland; and there are cards affixed to each lot, setting forth the particulars of the various modes of cultivation, quantity and quality of manure, time of sowing, and every particular which may be useful to the practical farmer, or others interested in husbandry.

Mr. HALKET has a miniature field set out, to show his new system called guide-way culture. It did not appear to us very feasible, and must involve, in a great degree, a new order of agriculture.

NICHOLSON'S celebrated haymaking machine has our unqualified praise. His assortment of machinery is exceedingly good; his dressing and screen machines are superior and cheap; he has a capital machine for breaking thick cake; grinding-mill, very serviceable. He was prevented showing his newly-invented 2½-horse power steam engine, owing to the regulations not permitting, as it weighed 1 ton 6 cwt. We saw some machinery we thought equally heavy. We hope in all cases one rule was adhered to.

SAWNEY exhibited his renowned hariff-screen attached to his almost equally-noted dressing machine.

STACEY had his barley-hummeller and chaff-cutters; the former has the long cylinder, in which revolves a spindle armed with steel knives in a spiral form.

SPILL—specimens of rick-covers, tarpaulins, horse-cloths, and other covers.

JOHNSON—his box-churns in variety, improved from the Yankee pattern.

IMPEY—turnip and mangold graters, Taylor's invention.

BRADLEY exhibits samples of his fattening food for cattle, &c.; horse or cattle 42s., pig ditto 24s. per cwt.

The mincing machines exhibited by Taylor and Buckingham must not be omitted—so simple and effective. Richmond's box-churn is worthy of better notice than we can afford. Humphries' double cider-press is a valuable aid to cider-makers: their winnowing-machines and perforated riddles are well known. Their clover-machine is good; and here we notice Smith's patent steam cultivator, of which they are agents, but which we cannot stay to describe. It is now before the world.

A. and T. FRY make up an interesting stand. Their double-press plough by Cousins, their corn-crushers, kibblers, root-graters, churns, draining tools, hand hay-rake, and other implements, demand an extended notice; but our space is more than filled.

F. M'NEIL and Co., as usual at all our great meetings, bring forward their asphaltic felt, so admirably adapted for cheap roofing.

GENERAL MEETINGS.

TUESDAY, DEC. 8 1857.

The Duke of Richmond, President, prevented attending, in consequence of being with his regiment of militia.

Cases of doubtful qualification of animals referred to Stewards.

Officers re-elected: President; vice-presidents; trustees; hon. secretary.

Mr. Quartly elected Steward of Cattle and Long-wool Sheep in place of Mr. Hole, who retires by rotation.

Mr. Henry Waters elected Steward of Short-wool Sheep, Cross-bred Sheep, and Pigs, in place of Mr. Frost, who retires by rotation.

New Members elected.

THURSDAY, DEC. 10, 1857.

Report of Stewards on cases referred to them presented.

Mr. B. E. Bennett's motion for a new Class for Welsh Steers under four years old, was not carried.

The Prize Sheet to remain as settled last year.

THE ANNUAL DINNER.

The annual dinner of the Smithfield Club took place on Wednesday evening, at Freemasons' Tavern. In the unavoidable absence of the President, His Grace the Duke of Richmond, the chair was taken by Lord Berners.

The attendance was larger than usual, the number present being about 160. The company included Lord Feversham, Lord William Lennox, Vice-Chancellor Kindersly, Mr. Western, M.P., Lieut. Col.-Towneley, Mr. Henry Wilson, Mr. C. T. Tower, Mr. H. Brandreth, Rev. Mr. Tooke, Mr. W. Fisher Hobbs, Mr. Mechi, Mr. W. Hole, Mr. Sandy, Mr. Torr, Mr. Brandreth Gibbs, Mr. J. Raymond Barker, Mr. R. W. Barker, Mr. S. Druce, Mr. G. P. Tuxford, Mr. R. W. Baker, Mr. Jonas Webb, Mr. Wilmore, Mr. Badham, Mr. Buckley, Mr. Corbet, Mr. Wortley, Professor Simonds, &c., &c.

The dinner, an excellent one, was admirably served. The musical arrangements were under the able direction of Mr. Genge, who had the assistance of Miss Wells, Miss J. Wells, Mr. Shoubridge, and Mr. Smythson.

On the removal of the cloth, the grace from the "Laudi Spirituali" was sung.

The CHAIRMAN then rose and said he had to express his deep regret, a regret which he was confident they all shared with him, at the unavoidable absence of the noble duke their President, in consequence of which he (Lord Berners) had, in compliance with the request of the committee, accepted the office of chairman that day. It was now his pleasing duty to propose to them "The Health of our illustrious and gaacious Queen" (cheers). This was a toast which ought always to stand upon its own merits, and it required no eulogium from him to ensure for it an enthusiastic reception. It might not, however, be unbecoming if at this particular juncture he added his fervent aspiration that an Almighty Providence might so direct her Majesty's councils that they might tend to secure a speedy restoration of peace in her foreign dominions, and increase the social happiness and prosperity of her people.

The toast was drunk with three times three, and followed by the National Anthem.

The CHAIRMAN would now give them "The Prince Consort, the Prince of Wales, and the rest of the Royal Family." The Prince Consort, he observed, had claims upon their respect, not only as the husband of our beloved Sovereign, and the father of that family in whom the hopes of England centred, but as the patron of arts and agriculture, and as a member and a successful competitor at the Smithfield Show (cheers).

Serenade.—"Bless'd be the Home."

The CHAIRMAN again rose, and said that there were certain times and circumstances which rendered the next toast especially interesting, and he thought it should be given on the present occasion in that assembly, although it had not been the custom at these annual gatherings to do so. The toast he had to propose was "The Army and Navy of England" (loud cheers). When he considered that the mind of every Englishman and every Englishwoman, and he might add of every man and woman in the civilized world, had for some time, and was even now, turned with absorbing interest to the achievements of our army in the East, he felt that he should hardly be doing his duty if he did not, at a meeting of British farmers such as this, give them an opportunity of expressing their respect and admiration for the military and naval services of their country (cheers). All hearts had of late been painfully affected by the unparalleled atrocities and barbarities that had been committed by the rebel troops in India. Their blood had run cold in their veins as they read the accounts which had reached them of the barbarities which had been perpetrated upon innocent and defenceless women, with children hanging at their knees, and infants at their breasts. The foul deeds which had been committed were, in short, such as were unrecorded in history. But as they contemplated them with the feelings of emotion they were calculated to evoke, they turned with hope to those gallant bands of our countrymen who were engaged in avenging the cause of outraged humanity, and to whose exertions alone we should owe it, if ever the territory of India was restored to the authority of the British crown (cheers). When they reflected on the comparatively small numerical force of the British troops in India, and the difficulties they had had to encounter in a climate and at a season of the year when it was thought almost impossible for European soldiers to traverse that country; when, notwithstanding this, they reflected upon the rapidity of their marches, their indomitable courage and perseverance, and the military skill which had been displayed by their intrepid commanders; that, unaided by reinforcements from home, they had contended successfully, not with an undisciplined rabble, but with troops disciplined by our own officers, armed with our own weapons, and having an artillery force in the city of Delhi alone that numbered 270 guns, manufactured in our own arsenals; that the military defences of that and other cities in revolt in India were all constructed by English engineers; and that the magazines and munitions of war in the hands of the rebels were almost unprecedented in amount—then he did say that the army of England in India was entitled to the gratitude and thanks of the country at large (cheers). And here he would mention the high compliment which had been paid to our government and army by the Emperor of the French—a compliment such has had never before been known, and which ought to be sounded in terms of praise from one end of the kingdom to the other; for it was a guarantee of the fidelity and of the friendship which the Emperor entertained and had expressed towards us (Hear). When the rebellion broke out in India, and it became necessary to send out reinforcements by the quickest route, the Emperor Napoleon, with the magnanimity for which he had rendered himself conspicuous, offered

to allow the army of England, in any numbers, to pass through France (loud cheers). Now, the Pacha of Egypt, acting in the same spirit, volunteered to facilitate the transit of our army across the Isthmus of Suez (renewed cheers). It was hardly necessary, perhaps, that he should mention the names of the heroes who had distinguished themselves during these troubles in India. They were "familliar in our mouths as household words;" still he might be excused if he referred to a few of those to whom they were anxious to do honour. There were Neill and Nicholson, and other brave men, who had fought and bled in their country's cause. There were others who, he trusted, still survived, and who only last night received from parliament an acknowledgment of their gallant services; he alluded to General Wilson and General Havelock (tremendous cheering). There were also Greathed (cheers), and Outram and Eyre of the Punjaub, the devoted Salkeld, unequalled for his gallant daring (cheers); Lawrence, Home, Wheeler, Chamberlain, Cotton, and Edwardes (loud cheers). All these had distinguished themselves by their heroic qualities and military skill, and had covered themselves with glory. He was sure, therefore, that the present assembly would, with the warm enthusiasm of grateful hearts, drink to the health of our Army and Navy. (The toast was drunk with loud and protracted cheering.)

Lieut.-Colonel TOWNELEY, in returning thanks, said that he had not the honour of being connected with the regular army, but he begged to say that he sympathised fully in the expression of admiration which had fallen from the Chairman for our gallant troops in India; and that he had taken the command of a regiment of militia for the sole purpose of giving greater facility to the efforts of our army abroad (cheers).

Glee—"Blow, gentle gales."

The CHAIRMAN would now propose to them what was generally considered, at these gatherings, as the toast of the evening, and he was happy to state that any difficulty he might have experienced in giving it had been entirely removed by the able pamphlet which their excellent Secretary, Mr. Gibbs, had recently published, and which contained a history of the Club from its commencement (Hear). He was quite sure that he only echoed the sentiment of every member when he expressed his thanks to Mr. Gibbs for the trouble and pains he had taken in drawing up that report (Hear, hear). It appeared, then, that the Smithfield Club was established so early as the year 1798, and that in 1800 it comprised only fifty members. In 1838 the Royal Agricultural Society of England was originated in this room, and he well remembered being present on the occasion, and being consulted, with many others, upon the subject. The statement contained in Mr. Gibbs' pamphlet, therefore, he could take upon himself to say was perfectly correct, and that the Royal Agricultural Society did derive its origin from this (Hear, hear). It was also noticed in the pamphlet that the show was removed from the inconvenient situation in Goswell-street to Baker-street, in 1839; and that her gracious Majesty visited the yard in 1844, and again in 1850. In 1841 the Prince Consort became a member of the Club; and how the institution had gone on and prospered to the present time all who were in the habit of visiting the show could tell (cheers). The members of the Club now numbered, he believed, about 300; and he might state, not as a matter of boast, but as a matter of fact, what could not be said of any other society in the kingdom, that with these 300 members they were enabled to give prizes to the amount altogether of £1,250 (loud cheers). The interest which their annual shows excited in the metropolis and throughout the country, proved the extent of the interest which was everywhere taken in agriculture, and that the community at large approved of the farmers of England uniting together for the purpose of devising the best means of producing for the population the greatest amount of animal food at the cheapest possible rate (cheers). Now, that was the main object of the club (Hear, hear). It was for that it was established, and in that it had succeeded. But notwithstanding the interest which was manifested in the show-yard, it was impossible to appreciate all the benefits which accrued to the country at large from the operations of the Smithfield Cattle Club (Hear, hear). It was all very well for their friends in London to go into the yard and admire a beast; but they should go into the country, into the country markets, and into the tenant farmers' homesteads and the tenant farmers' fields. There they would see for themselves the increased value given to cattle. There they would see the aptitude to feed and fatten, and there they would see the development of early maturity; all of which showed that the club were doing good service to their country by promoting the production of the largest amount of food for the people at the smallest possible cost. He would detain them no longer, but at once give "Success to the Smithfield Cattle Club."

The toast was drunk with three times three, and great applause.

Mr. GIBBS, the Honorary Secretary, then read the list of winners of the gold medals at the exhibition of the club for the present year.

The CHAIRMAN, in presenting the gold medal for the best steer or ox in any of the classes to Mr. Wortley, congratulated that gentleman on his success, and expressed the pleasure he felt that the medal would be taken into his own neighbourhood. In conclusion, he proposed Mr. Wortley's health.

Mr. WORTLEY returned thanks, and assured the company that he felt the highest pride in being able to contribute another laurel to the chaplet worn by the agriculture of his native county.

The CHAIRMAN next presented Colonel Towneley with the gold medal for the best heifer or cow in any of the classes, and announced that that was the twentieth gold medal which the gallant colonel had won in various parts of the kingdom (cheers). He begged to propose his health.

Lieut.-Colonel TOWNELEY acknowledged the compliment, and assured them that he esteemed it a very high honour to be a second time the winner of the gold medal of the Smithfield Club. His success, however, he attributed more to the judgment and skill of the gentleman from whom he had obtained his herd, than to any merits of his own. He got that herd from a gentleman who had been bred up with a knowledge of the good points of an animal from his youth, and when he (Colonel Towneley) came into the estate, that gentleman, having more to do than he could well manage, gave up his herd to him; and that was the commencement of his own operations. He had now been in the trade, he might say, about eight or nine years; and another cause of the success he had achieved was that he had always endeavoured to get the best males and the best females together. If they got really good blood they were almost certain to produce a good animal. The ox which he had had the pleasure of showing in the yard this year was from a common milking cow which he had bought in the market. He forgot the price he had paid for her, but it was certainly under £20. The ox, he believed, was not a bad one; and it had been produced by a single crosa with a good bull. Indeed, he could not recommend farmers to do better than to get a good male animal for whatever stock they happened to have. He had placed a good bull at the disposal of his tenants, and he believed that by this means he had improved the value of their stock from £1 to £3 a-head (cheers). It should not be forgotten, either, that the most valuable animals were good milkers as well as good breeders (hear, hear).

Lord FEVERSHAM then presented the gold medal awarded to the best pen of long-woolled sheep in any of the classes, to Lord Berners.

The CHAIRMAN said the pleasing task now devolved upon him of proposing the health of their President, his Grace the Duke of Richmond, as the winner of the gold medal to the best pen of one year-old short-woolled sheep (cheers). Than the name of the Duke of Richmond, he was sure there was none more acceptable to the farmers of this country (Hear, hear). At periods when the interests of agriculture had been assailed, they had known him as the faithful friend of the farmer, and such they had invariably found him to the present day. He regretted the absence of his noble friend on this occasion; but it arose entirely from a sense of duty. His noble friend was devoting himself to completing the organization of the militia of his county, and in a letter which he had written to the Society he stated that he did not wish to be absent from that militia a single day, whilst he thought his presence amongst them was of importance. If he (Lord Berners) might be allowed to address a word to his brother-farmers in reference to the militia, he would observe, that it was in the power, as it was the duty, of each and all of them in their several stations, when they returned to their homes, to assist in recruiting by volunteers that truly constitutional force (Hear, hear). And let them remember that every man who joined the militia at the present moment was filling the place of one of those known and tried soldiers who had been

sent to that part of the world where their services were most required in the interests of the country (cheers). With these remarks he begged to give, with three times three, "The Health of his Grace the Duke of Richmond, the President of the Club, and a winner of the gold medal" (cheers).

The toast was drunk with enthusiasm.

Song by Mr. Shoubridge—"The Yeomen of England."

Lord WILLIAM LENNOX said, on rising in obedience to a call from the chair, he must claim the indulgence of the assembly, as he was not prepared when he came there to take part in the proceedings of the evening. He had come in the expectation that his brother would be there; and it was not till after entering the room that he learnt that he was detained on duty. The diffidence which he always felt on rising to address a public assembly was increased on that occasion by the feeling that he stood there alone, probably, in perfect ignorance of land and cattle, and of anything appertaining to agriculture. They were all aware that a younger son of a noble family did not inherit a very large portion of the broad acres of his ancestors; they were probably aware that his share of the soil generally consisted of the mignonette-pots outside his window, and his live-stock of a half-starved pointer (laughter). It was not necessary, however, either to own land or to breed stock in order to understand the benefit conferred on the country by a society which aimed at securing good and cheap food for our rapidly-increasing population (Hear, hear). Having explained the position in which he stood, he now begged to thank them, on behalf of his brother, for the kind manner in which they had drunk his health. In early life his brother entered, along with six of his brothers, the profession of the army. He saw service under the Duke of Wellington; and perhaps what he had most reason to be proud of in his military career was the fact recorded by Napier, that he left the staff of Wellington to do duty as a regimental officer of the line (Hear, hear). Those times were now long past; but his conduct with regard to the militia was such that he might fitly be compared to an old warhorse, who, on hearing the sound of bugle or trumpet, immediately manifested a determination to live or die in active service (cheers). As an illustration of that sort of feeling, he might mention that about Christmas last year, his regiment being at Brighton, he left a comfortable home to dine with the officers; and when he got there he found only an ensign and an orderly officer, all the rest having gone away Christmasing (laughter). That showed how much his heart was wrapped up in his regiment. He (Lord W. Lennox) trusted that under the new state of things no difficulty would ever be experienced in obtaining recruits for the army. As long as a portion of the money nominally paid to the men was deducted on various pretences, it was natural to suppose that there would be a scarcity of recruits; but now that the recruit knew exactly what he was receive, and so much encouragement was given to the soldier, he thought they might expect to see the ranks of the army not only filled, but comprising a better class of men than formerly entered the service. To return to his brother. He was quite sure that nothing but a regard for military duty would have prevented him from occupying the chair. He believed he was at Dover, where his militia regiment was stationed; and that the cause of his absence was a little unpleasantness between that regiment and a regiment from Ireland, which he was desirous of removing. He should tell him of the manner in which his health had been drunk, and he was sure he would be gratified at receiving the information. Might he long be spared to preside over that excellent institution, and to promote as far as he could, in public and in private, the interests of the agriculturists of this country! (Cheers).

Lord FEVERSHAM said the duty had devolved upon him of proposing the next toast, and it was one which he was sure every gentleman in that room would receive with the warmest feelings of gratitude, being the health of his noble friend Lord Berners, who had so ably and efficiently discharged the important duties of the chair that evening, in the absence—in the unavoidable absence, as they had just been informed—of the President of the Club, the Duke of Richmond. In proposing that toast, it would be superfluous in him to detain them by offering any observations of eulogium or commendation. His noble friend was well known to the agricultural community as a practical farmer. He had long devoted a large portion of his time and attention to agriculture; he had made it his study, and he was at all times ready to impart information to those who consulted him on subjects of importance. His noble friend was, as they were aware, not only a practical agriculturist, but also a successful exhibitor of stock (Hear, hear). The gold medal had just been presented to him in that capacity; and perhaps he (Lord Feversham) might be allowed to observe, that his own county—York—had partly contributed to his noble friend's success on that occasion, inasmuch as his beautiful sheep were descended from a flock belonging to a gentleman who resided in his (Lord Feversham's) neighbourhood. They were aware that his noble friend now filled the important office of President of the Royal Agricultural Society. He was confident that in presiding over the proceedings of that great institution he would always manifest ability, fairness, and judgment; and that whenever any suggestions were made in the council with a view to improvement, however humble might be the person that made them, they would be listened to patiently, and receive due consideration. He might add, that it was the opinion of some eminent members of that society that there was still room for improvement; and he hoped that if any observations were made in relation to that subject at the meeting to be held on the following Friday, his noble friend would receive them with that courtesy for which, no less than by his firmness, he had always been distinguished. He had no doubt that his noble friend would retire from office with a reputation for ability inferior to that of none of his predecessors. He would now propose that they should drink, "Lord Berners, and Success to the Royal Agricultural Society of England."

The toast was drunk with great enthusiasm.

The CHAIRMAN said his noble friend and school-fellow Lord Feversham had imposed upon him one of the most difficult tasks he had ever been called upon to perform. He had mentioned his name in so many different points of view, that he hardly knew where to begin or where to end, and therefore he thought he had better discard all the compliments which had been paid to him, and once for all thank the company, as he did most heartily and sincerely, for the honour which they had done him, by the manner in which they had received the toast. There could not, in his opinion, be a higher compliment paid to any man than by his name being well received by the farmers of England. From his earliest youth he had been in the habit of meeting the cultivators of the soil in every part of the country. It was from that great patron of agriculture Mr. Coke, of Holkham, afterwards Lord Leicester, that he received his first instructions in agriculture, and from that time to the present he had constantly met with the greatest kindness at the hands of English farmers. His name had been coupled with that of the Royal Agricultural Society, of which he had the honour that year to be the president. He could only say that it would afford him the greatest gratification to see the meeting at Chester rival, if it did not exceed, as he expected it would, all the preceding meetings of the society (cheers). He could assure his noble friend that he was not mistaken in supposing that he would be prepared to listen attentively to any suggestions that might be made for the improvement of the society, and especially would this be the case if they proceeded from practical farmers. It was by the union of science with practice that the council aimed at carrying out the objects of the society—objects of national importance, and of a similar nature to those of the Smithfield Club. That day the council had agreed to their report, and it might not be uninteresting to some present to hear a little about their proceedings. It appeared that during the last year they had gained an accession of 150 members, and that the total number was now 5,218. There was one subject which the society had taken up, for their conduct with regard to which he thought the farmers of England ought to feel especially grateful to them. When it was reported that a terrible plague was prevailing among cattle in Austria, Prussia, and other continental countries, the Royal Agricultural Society, acting in conjunction with the Highland Society of Scotland, and the corresponding society in Ireland, took up the matter, and sent over Professor Simonds to ascertain the causes of the prevailing disease. The Professor had since made his report, and he trusted it would shortly appear in the society's Journal (cheers). He might also mention that at the Salisbury Meeting the visitors exceeded by 2,000 the number that attended on any former occasion (Hear, hear). At the Chester Meeting, the prizes would exceed in amount those that had ever before been offered by any local society; he believed the amount would be

upwards of £1,200. The society had done much to diffuse sound principles in reference to agriculture, and, having regard to that general fact, and especially to the improvement which it had been instrumental in effecting, by bringing forward imp'ements combining cheapness with simplicity and efficiency, he thought it might be said that the society had not failed to perform its duty (Hear, hear). He hoped that all present would endeavour to come to the meeting at Chester, and to bring friends with them, and that he should be enabled to feel that the society had not suffered in efficiency and usefulness during his presidency.

Ballad by Miss M. Wells—"Oh, yes, I love thee."

Vice-Chancellor KINDERSLEY said—In obedience to a command—for he considered a request from the Chairman equivalent to a command—he rose to propose a toast, with which he had the honour to be entrusted. He must begin by apologizing for venturing to address an assembly of persons familiarly acquainted with agriculture, he himself being entirely ignorant on that subject. Though he had the honour to be a judge in equity, he confessed he was no judge of Southdowns or Leicesters (laughter). With regard to cattle, he believed he did know a poll-cow when he saw one; and when he met with the word poll-cow, it was involuntarily associated in his mind with a deed poll (laughter). He knew nothing of the distinction between longhorns and shorthorns; the only horns with which he had any familiarity were the horns of a dilemma in argument (renewed laughter). But, although he was profoundly ignorant on this subject, he was not so unobservant of what was going on in the improvement of agriculture as not to feel astonished at the extraordinary success which had attended the efforts of that and similar societies. Particularly had he observed the advance made in the case of pigs, of which he begged to say he was no less ignorant than of cattle; but when he saw the outward improvement which had taken place in the skins of pigs, and observed the gradual refinement of their coats, he could not doubt that in time they would be able to realize the making of a silk purse out of a sow's ear (laughter). Although he was unconnected with agriculture, he might not perhaps be altogether out of place there. He did not, indeed, belong to the class of breeders, not to the class of feeders, nor to another class, without whom he presumed they would find it difficult to get on, he meant the butchers; but he belonged to a class without whom he would like to know how they would get on at all, namely, the consumers (Hear, hear); and it was as a humble representative of that very numerous and by no means unimportant class that he ventured to address them. But looking at this matter in a more serious point of view, he confessed that he felt very deeply impressed when he found himself in the presence of gentlemen who were concerned in the pursuit of agriculture, and more particularly of gentlemen who were engaged in the breeding of cattle. He felt that he was in the presence of those who were the descendants and representatives of the old yeomen of England—the backbone of the nation—who had for centuries past maintained the vigour, and force, and character of this country in a manner with which they were all familiar historically, and of which they were all justly proud (cheers). Moreover, the interest which attached to that society was enhanced by the fact that the gentry and aristocracy, including some of the highest nobles in the land, united with the farmers in efforts to achieve what was undoubtedly a work of great public importance, namely, the increasing the quantity, improving the quality, and cheapening the price of what was a most important article of food in this country (Hear, hear). Still more was this the case when even the highest personage in the realm, next to the Sovereign, did not disdain to enter the arena and compete with the farmer; and he might add that he had no doubt his Royal Highness was very glad when he obtained a prize (laughter). In this respect the society had established an equality of the right sort—an equality which was perfectly consistent with the gradations and ranks of society. He had now to propose the health of certain gentlemen, who filled certain offices in that society, and who in filling them rendered, he was convinced, the greatest service to it; he meant the Vice-presidents and Trustees, including the Honorary Secretary, who, he was informed, was one of the trustees, and who, in addition to his other services, had recently prepared a history of the past proceedings of the club, which he was sure would be read by agriculturists in general with deep interest. If he might be forgiven for taking such a course in the presence of those to whom he had no right to suggest a word of advice or admonition, he would before sitting down remind the farmers of England of what appeared to him a very important part of their duty in this most momentous crisis. It was, of course, of the utmost importance at the present time that the ranks of the army and that of the nursery of the army, the militia, should be well and adequately filled; and he would suggest that it was a real duty devolving on every farmer and every landed proprietor in this country, instead of doing what he was afraid some individuals had done—he was sure none present had taken that course—namely, discouraging enlistment; it was, he submitted, the duty of all such persons to encourage the labourers to enrol themselves in the militia, in order that, in the absence of the regular troops, the shores of this country might not be left without that defence which from the earliest periods in our history, from the Normans, the Plantagenets, and the Tudors downwards, had always formed the greatest security of the nation (cheers).

After a cordial response to the toast,

Mr. BRANDRETH GIBBS, on rising to reply, said he regretted that it should have again fallen to his lot to return thanks on behalf of the Vice-presidents and the Trustees. He regretted it, first, because but for the unavoidable absence of his Grace the President this duty would have devolved on their noble chairman; and secondly, because the Vice-presidents and the other Trustees were also absent. He sincerely thanked them, however, for the manner in which the toast had been received; and for himself he would say that he was alwaya delighted if his conduct met with approbation. The present show seemed to him to mark a positive step in advance, whether they looked at the number of animals exhibited, or whether they looked at the more fully-developed classification of breeds under which the stock was now exhibited. When this classification was introduced three or four years ago, it was regarded by some as an innovation, by others as an improvement; but in that little pamphlet which he had published he had shown that this classification was nothing new, but that the club had only reverted to a practice which existed in it some fifty years ago (Hear, hear). He thought the recurrence to the former custom in that respect had proved most beneficial. If they recalled the number of Devons exhibited a few years back, and then took a glance at the long range of such animals exhibited this year, they would perceive that the breeders fully appreciated the alteration (Hear, hear). He would not detain them longer, but, again thanking them for the compliment which had been paid to the Vice-presidents and Trustees, he would conclude by observing that if the little pamphlet of his which had been referred to proved acceptable and useful to the members, he did feel amply repaid for the time and labour which he had bestowed upon it (cheers).

Duet, by the Misses Wells—"We come to thee, Savoy."

Lord W. LENNOX proposed, "The Unsuccessful Candidatee," coupled with the names of Lord Feversham and Mr. Druce, junior. After some eulogistic expressions with regard to Lord Feversham, he said he had been informed that his lordship was successful as the exhibitor of a short-horned heifer at Birmingham, though he had not succeeded in London; and he was convinced that he had too much of the pluck of an Englishman to cease exhibiting in Baker-street because he had failed this year (cheers).

The toast having been duly honoured,

The CHAIRMAN said he was sure that if either Lord Feversham or Mr. Druce could give the company any information of a practical character, it would be gratefully received. He should be glad if his old friend Mr. Druce could tell them how he and his neighbours had succeeded in bringing the cross-breed to such perfection as they had done.

Lord FEVERSHAM said, as one of the unsuccessful candidates, he begged to return thanks for the honour which had been conferred upon them. As regarded his failure that year, he must observe, that had he ceased exhibiting when he was first unsuccessful, he should have stopped long ago (Hear, hear); and they might rest assured that his want of success that year would not deter him from coming forward again (cheers). It happened that in the very first year in which he exhibited in Baker-street, namely, in 1850, he obtained the first prize in his class, and

the result was similar in 1851; but it did not follow because a man had bred a good animal one year or two years in succession, he could always do so. He assured them he had found the greatest difficulty in breeding anything like a perfect animal; and an animal must certainly be as nearly perfect as possible to give anyone a chance of carrying off a prize (Hear, hear). When he wanted a cross, he meant fresh blood, he generally had recourse to the large short-horned sales; and when he saw an animal that he liked, he did not mind bidding a high price for him (Hear, hear). Thus, some time ago he bought two very nice bull-calves at the sale of Lord Ducie's, each of which weighed about 420 lbs., neither being then more than six months old, and the result was very satisfactory. One of them gained a prize of 1,000 francs at Paris, and he afterwards sold it to a gentleman for 200 guineas. He agreed with Col. Towneley, that in breeding the great object should be to bring a good male and a good female together. It was an entire mistake to suppose that provided the male were good, it was comparatively unimportant what the female was (Hear, hear). Some difference of opinion existed as to what was most desirable in the case of short-horned cattle: he agreed with the late Mr. Bates that it was most desirable to have animals with nice soft hair, and thin—not too thin—soft, supple skins. He was convinced that such animals were the most easily fed, and would thrive the best. He had adhered to the principle of crossing the herd followed by the late Mr. Bates; and he was told that the farmers in his neighbourhood found that the cattle descended from his bulls fetched higher prices in the market than those which were not so well bred. He again returned thanks on behalf of the unsuccessful candidates, and repeated that he did not intend to cease exhibiting because he had not this year obtained the prize (cheers).

Mr. DRUCE, jun., also returned thanks, and said he hoped that next year he should be successful (Hear, hear).

Mr. WILSON, on rising to propose the next toast, observed that he could not say with their excellent friend Vice-Chancellor Kindersley that he was entirely unacquainted with agriculture; for although it might be long before he appeared as a competitor, his position was happily that of a learner. As regarded the learned judge, he might safely declare that all present would be glad to meet him there on future occasions, and that they would much rather meet him there as often as he could come than only once in the Court of Chancery (laughter). The toast which he had to propose was, "The Judges." They would, he was sure, all agree with him that those gentlemen occupied a very proud position; and unless the greatest confidence were reposed in them, it would be impossible for them to discharge their duties satisfactorily (Hear, hear).

Before the toast was drunk, the CHAIRMAN expressed a hope that the judges might be induced to make some practical remarks in reference to the breeding and fattening of animals.

The toast having been drunk with proper spirit,

Mr. BUCKLEY replied on behalf of the judges.

The CHAIRMAN then proposed "The Stewards," and in doing so repeated the invitation which he had just given to the judges.

Mr. HOLE briefly acknowledged the compliment.

Song by Miss J. Wells—"Bid me discourse."

The next toast was, "The Father of the Club, Mr. Wolstead."

The CHAIRMAN then proposed "The Butchers." He observed that the Club now offered a premium to the butcher who was the largest purchaser at the show; and said the tenant farmers of England would be glad to see among them some representatives of a class who were their best customers, on an occasion like that. The noble lord coupled the toast with the name of Mr. Jeffrey, the winner of the Butcher's Medal last year.

The toast having been duly responded to,

Mr. SAWTELL, cattle salesman, said, on behalf of Mr. Jeffrey, who was a particular friend of his, he begged to return thanks for the toast. At the same time he would take the liberty of calling his lordship's attention to the very serious injury which was being inflicted on butchers through the exercise of the power vested in the magistrates of doing away with private slaughter-houses. It would be of no use for such beautiful animals to be brought to London if they had to go to a common slaughter-house to be killed (Hear, hear). The abolition of the private slaughter-houses would impose on butchers an extra expense of £183,000 a year; and he would leave it to his lordship to judge whether that burden must not ultimately rest on the consumer. He concluded by handing to the Chairman, and several gentlemen near him, a printed statement with regard to the loss which the change he complained of would throw upon the trade.

The CHAIRMAN said, by the rules of the Club they were precluded from discussing any subject that was likely to come before Parliament; but this he would say, that if there were any measure which injuriously affected the interests of the butchers of the metropolis, and therefore the tenant farmers of England, it would be his duty and his earnest desire to give his best attention to it where he could attend to it with propriety (cheers).

Irish ballad by Mr. Genge—"O, it'a time I should talk to your mother."

Mr. WESTERN, M.P., said he had been called upon to propose a toast, and he supposed the reason was that he happened to have a name which was formerly somewhat distinguished in the agricultural world, and belonged to a county which was rather celebrated for agricultural improvements. The toast was, "The health of the labouring classes;" and he was quite sure that in a meeting of British farmers it would meet with a cordial reponse (cheers). The farmers throughout the country now felt the necessity of endeavouring to diffuse intelligence and sound morality among the labouring population; and this not less for their own sake than for the sake of the labourers (Hear, hear). As the Vice-Chairman had alluded to the subject of recruiting, he would observe that now that such brilliant prospects were held out to recruits, it must be quite unnecessary to cripple the number of agricultural labourers required for the cultivation of the soil (Hear, hear). Having, as a member of the House of Commons, been summoned to London to consider the Bank Act of 1844, he rejoiced to find, as one result of his arrival in town, that this country had a large surplus in the Bank of England; and he hoped it would continue to increase. He would give, "The Agricultural Labourers."

The toast was received with much cordiality.

Madrigal, by all the singers—"Down in a flowery Vale."

The CHAIRMAN said, in parting with those whom he saw before him, he could not help saying how grateful he was for the kind support which he had received that evening; and he felt that he should not be doing his duty if he retired without giving a sentiment which was always given on similar occasions by the late Lord Spencer, namely, "Sorry to part, but happy to meet again" (cheers).

The company separated at about half-past 10.

METROPOLITAN CATTLE MARKET.

THE GREAT CHRISTMAS CATTLE MARKET.

MONDAY, Dec. 14.—Notwithstanding that the consumption of food has unquestionably fallen off, owing to the late panic in the commercial world; and although the prices of fat stock have, consequently, shown a tendency to give way, we never recollect a period during which so much general interest has been shown in reference to our fat stock shows as was the case here this morning. At an early hour the market was thronged with visitors from nearly all parts of the United Kingdom, as well as from the continent, to inspect and admire perhaps the finest collection of animals ever shown in this or any other market in the world. As the day

advanced, the number of visitors rapidly increased, yet, from the enlarged space included in the market's area, there was ample room for close inspection without inconvenience.

That the show of Beasts was of the highest order of merit will be understood when we observe that fully nine-tenths of them were considerably *above* average weight, and otherwise in unusually fine condition. The increase, be it understood, was not so much in the quantity of fat carried by the collective breeds, as in their general symmetry. As was the case at Baker-street, there were not so many "obese marvels" as in some former years; but the absence of *extreme* fatness may be noted as one of the great merits of the present show. The fat being laid on evenly and well is the result of well-shaped and well-bred animals being in more general demand on the part of the butchers and consumers. Formerly, by dint of stuffing, fat was often deposited everywhere save in the right places; and the result was that the buyers of both Beasts and Sheep lost considerable sums by the stock when slaughtered. We hail this change in the system with much satisfaction, because we are perfectly convinced that our breeders and feeders have at length got into the high road to additional fame.

From the foregoing observations, it will be seen that the supply of Beasts was one of no ordinary merit, and we may now briefly glance at *each* of the leading classes, the more fully to determine their positive excellence. These classes we may call Scots, Herefords, Devons, Shorthorns, Sussex, and Welsh. When we consider the great disadvantages, as to climate, under which the Scotch graziers are suffering, compared with those residing in the "sunny south," great surprise may well be expressed at the wonderful animals which were shown from the "far North." Whether we carefully consider the high value of their primer, consequently most selling, parts to the butcher, and the superior quality of the inferior joints, it must be admitted that the word "perfection" may be fairly applied to them. Those who witnessed the splendid collection of Scots, the property of Mr William Mc Combie, of Tillyfour, exhibited by Mr. Daniel Maidwell, will at once understand the bearing of these remarks. Not a fault could be found with them; though, on the other hand, it is to be regretted that they should have been reserved for an open market; still, they added greatly to the show, and proved to the world what Scotland really can produce. Mr. Mc Combie's ox exhibited in the bazaar was purchased by Messrs. Banister and Bedborough, of Windsor, to supply the royal table on Christmas-day.

The collection of Herefords has seldom, if ever, been equalled. Amongst it were very few what may be termed large animals, the supply being almost wholly composed of a size admirably suited for general consumption. As regards the Devons, the excellence of their condition was fully equal to the Herefords, and the "men of the West" mustered in full average strength. The Short-horns, too, were of more than average merit. There was everything to admire in them, even though the fat was not "plastered" upon them so much as at some former exhibitions. From Sussex there was an increased show of Oxen, all in first-rate order; but the graziers in that county can do even greater things by a more extended cultivation of the turnip. They have now a wide field opened to their enterprise and industry from a separate class having at length been allotted to them in Baker-street. There were about 300 extraordinarily prime Welsh runts on sale, and which elicited the marked encomiums of the visitors.

As regards the Sheep here to-day, we must admit that the supply, taken as a whole, fell short of our expectations. True there were some very fine and very large animals on offer; but the bulk of the show was of a second-rate character. And here is the result of premature forcing, and of what is termed "early maturity;" whilst, no doubt, an unfortunate selection of stock for crossing purposes has led to a decreased size and supply. Exceptions, however, should be noticed, and we have no hesitation in referring to choice specimens of the Lincolnshire long-woolled breed direct from that county. They were shown by Messrs. Eland, Hancock, Woodward, and Smith, and comprised 30 from the flock of Marshall Heanly, Esq, of Croft; 10 from H. Seals, Esq., of Wainfleet Hall; 29 from J. Byron, Esq., Marblethorpe Hall; 50 from George Saul, Esq., of Wrengle; 20 from — Bealbry, Esq., of Wigtoft; and 20 from R. G. Chatterton, Esq., of the latter place. There were also a few splendid Sheep of the same breed, the property of J. Cook, Esq., of Norfolk. The whole of them possessed that peculiar quality which the county of Lincoln is noted for producing, viz., a large proportion of meat, compared with size. In this respect the breed must be considered superior to what are termed the New Leicester. From Norfolk, Suffolk, Essex, and Sussex some fine Sheep came to hand.

The following return shows the numbers of Beasts shown, and the highest and lowest prices obtained for them on the great days in the last seventeen years:—

Year.	Beasts shown.	Prices. s. d. s. d.
1840	3,528	4 4 to 5 8
1841	4,509	3 8 „ 5 0
1842	4,541	3 4 „ 4 8
1843	4 510	2 8 „ 4 4
1844	5,713	4 0 „ 4 6
1845	5,326	3 6 „ 4 8
1846	5,470	4 0 „ 5 8
1847	4,282	3 4 „ 4 8
1848	5,942	3 4 „ 4 8
1849	5,765	3 4 „ 4 6
1850	6,341	3 0 „ 3 10
1851	6,103	2 8 „ 4 2
1852	6,271	2 8 „ 4 0
1853	7,037	3 2 „ 4 10
1854	6,181	3 6 „ 5 4
1855	7,000	3 8 „ 5 2
1856	6,748	3 4 „ 5 0

The total imports of foreign stock into London last week amounted to 1,773 head. In the corresponding week in 1856 we received 1,622; in 1855, 4,752; in 1854, 3,999; in 1853, 6,316; in 1852, 4,436; in 1851, 4,277; and in 1850, 5,124 head.

IMPORTS INTO LONDON LAST WEEK.

FROM WHENCE.	BEASTS.	SHEEP.	CALVES.	PIGS.
Rotterdam	64	528	106	—
Harlingen	149	833	18	—
Schiedam	46	—	—	—
Antwerp	—	—	29	—
Total	259	1361	153	—

YEARLY COMPARISON OF WEEKLY IMPORTS.

	BEASTS.	SHEEP.	CALVES.	PIGS.
1856	499	919	204	—
1855	859	3555	238	—
1854	1130	2593	269	7
1853	1136	4698	462	20
1852	235	3782	419	—
1851	607	3155	363	152

We may here observe that great dissatisfaction was expressed, both by the salesmen and graziers, at the large increase in the tolls for stock now levied by the city authorities. The old and present charges we here subjoin:

LIST OF MARKET CHARGES.

	Old charge.		Present charge.	
	s.	d.	s.	d.
Sheep (per score)	0	2	0	4
Beasts (per head)	0	2	0	3½
Calves „	0	1	0	2½
Pigs (per score)	0	4	0	6
Whole pens for sheep, calves, and pigs	1	0	1	0
Horses (each)	0	6	0	7½
Donkeys „	0	6	0	3

This great increase will, if we mistake not, produce a material falling off in the supplies of stock in future: but why *donkeys* should be so highly favoured as to have *a reduced* tollage, we leave others to imagine.

A portion of the unsold stock exhibited in Baker-street was here to-day. Amongst it, we noticed a short-horn, the property of Sir Thos. Whicheote, Bart., which took the second prize of £10. In addition to the Beasts from Scotland already referred to, Mr. D. Maidwell had on show some wonderful Short-horns, over 210 stones, forwarded by Messrs. Wiseman, residing near Spalding, as also some prime animals of the same breed, fed by E. Sheringham, Esq., of Croxford Abbey, Norfolk.

On the stand of Mr. Robert Morgan, we observed one of the most even lots of Beasts ever sold by any one salesman. They were forwarded by the following breeders: Wm. Thomas, Esq., of Holbeach; the executors of the late Robert Cook, Esq., of Rostland;—Fisher, Esq., of Weston, near Spalding; L. Bird, Esq., of Farcet End; W. Hewson, Esq., of Crowland; Robert Leeds, Esq., of West Lexham, Norfolk; Edmund Farrer, Esq., of Sporle; Josh. Freeman, Esq., of Dersingham; John Allday, Esq., of Lolehill, near Birmingham; and from Messrs. Martin, Cooper, Mitchell, Stoddart, Milne, &c., residing in Scotland.

Messrs. Giblett and Gurrier exhibited some remarkably fine animals, fed by Messrs. Milne, Steward, Mennie, Martin, Garden, &c., residing in Scotland, besides some prime breeds from the home-counties.

Mr. William Collins showed some wonderful Beasts, the property of John Hudson, Esq., of Castleacre, Nortolk; Mr. T. Scrivener, of Stunton; W. Brands, Esq., of Great Stace; and Mr. W. Shaw, of Cotton End.

Mr. Thomas Dixon had also a good show of Beasts, fed by the Marquis of Exeter, Sir Thomas Whichcote, Bart., Mr. Duckets, contractor, of Bermondsey, Mr. John Little, and others.

Mr. Vorley's stand was well filled with good symmetrical stock, forwarded by Mr. Sweeton, of Lincolnshire, Mr. J. Seppings, of Norfolk, and Mr. Cooper, of Hilbrae, N. B.

Considering the immense supply in the market, and its unusually fine quality, there was what may be termed a fair demand for most breeds. A few very superior Scots sold at 5s. per 8 lbs.; but the general top quotation for Beef was the same as on Monday last, viz., 4s. 8d. per 8 lbs.

We have before alluded to the general quality of the Sheep; but we must here notice those offered by Messrs. Weall. They were certainly very prime animals, and comprised 20 Downs from Richard Wakley, Esq., of Lawrence End, near Luton, Beds; 70 Gloucesters from Richard Rowland, Esq., of Creslow, near Aylesbury; and several pens from Berkshire, Oxfordshire, and Hertfordshire. At the stand of Mr. Gurrier were some extraordinary Cotswolds, bred and fed by the Messrs. Hewers and others; also some fine half-breds from Mr. Edmonds, together with several pens of good Downs. Some of the Cotswolds realized £7 each. We understand that the latter breed is becoming more generally used for crossing purposes.

Mr. Starkey exhibited 20 very good half-breds, the property of the Earl of Leicester, of Holkham; and 50 from S. Abbott, Esq., of Castleacre. Messrs. Parkinson and Mawer exhibited 5 wonderful Lincolns, fed by Marshall Healley, Esq., of Croft; and some of the same breed, forwarded by R. Everard, Esq., of Fulney-house, near Spalding. There were 6 very fine Hampshire Downs shown by Mr. G. Bullock, bred by Mr. Sharp, of Remenham, Henley-on-Thames. This gentleman took the first prize in the Show-yard.

The total number of Sheep in the market was only moderate. For nearly all breeds the demand was inactive, but without leading to any quotable change in prices compared with Monday last. The best old Downs sold at 5s. 4d. per 8lbs.

Calves were in short supply, and good request, at a further advance in prices of 2d. per 8lbs.

In Pigs only a limited business was doing, at late rates.

The arrivals of Beasts from Lincolnshire, &c., were 3,600 Shorthorns; from other parts of England, 2,800 Herefords, Devons, &c.; from Scotland, 700 Scots; and from Ireland 200 Oxen. The show of foreign stock was very limited.

THE SMITHFIELD SHOW WEEK.

The Smithfield Club Show has fully realized all that was expected of it. The chorus of our song is still the same—it was the best meeting ever known. There was a great increase in the entries of stock, while the animals were generally remarkable for their excellence. These have of late years been the strong features in the progress of the Club. Its influence has tended to multiply the good and to diminish our supply of inferior sorts. There are far more Herefords and Devons than ever. The Shorthorns hold their ground, and other meritorious races come gradually to assert and develope their good qualities. This was especially the case with the Sussex beasts, of which there was a most commendable entry. In fact, no varieties would appear to be getting more into repute just now than this kind, and their distant relatives the Devons. The latter, after having been for some time comparatively in the shade, are regaining their position very rapidly. Individually they nearly always show well, but for some time we have seen them but scantily represented. They are now, however, becoming once more numerically strong. We should question, moreover, whether so many of them have ever been brought into the focus of one meeting, as we have been enabled to count up within this last week or two.

A further proof of what the Club is effecting for an increased supply of the best meat is to be found in the new names on the prize list. The Gold Medal ox at Birmingham, and the best of his breed in Baker-street, was fed by a gentleman who had never previously exhibited a beast at anything beyond a local meeting. The Gold Medal ox of the Smithfield Club was both bred and fed by another who had never ere this entered his name upon the catalogue. It is not all now King, Queen, and Knave—or, Knave, Queen, and King; but

we have fresh men, both as breeders and feeders, competing successfully against others that but a few seasons since were held to be almost invincible. Nobody will say but that this is all in favour of that great object the Club has set itself to achieve. At the same time the lesson has been thoroughly learnt. Although we have new men with good animals, we have none such with bad or indifferent. They have taken careful observation of the place before they have ventured to enter it. There was a time when you could the more readily appreciate the superiority of a prize animal from the comparison with those which stood beside him. By this we have no such marked difference. The labours of the judges are yearly becoming more difficult and trying; and many a one of us, who bows at once to their decree, would be likely enough, and with very good showing, to make another choice for himself. The placing of the same animals in Bingley Hall and Baker-street was often at direct variance. Animals passed over one week were the selected of the next, and vice versa. In a word, they were nearly all prize beasts.

As we give in another place a full report on the merits of the several classes, we need not repeat ourselves here. There are one or two especial points, however, that we may touch on. The first of these relates to unquestionably the best animal in the show-yard — Colonel Towneley's short-horn. It now turns out that this cow is *not*, as was supposed, intended for the butcher; but is to be still kept on for breeding. She is, in fact, declared to be in-calf. This announcement has caused considerable discussion during the week. Many contend that such a proceeding is in direct contradiction to the principle of a Society that annually offers a premium to the butcher who purchases to the largest extent in the yard. Others, again, maintain it to be a triumphant vindication of the Towneley theory, that, let stock be ever so fat, if they be only of the right sort, they will still breed. As a rule, though, we imagine that it would be rather dangerous to adopt a practice that goes to say the best way to prepare an animal for breeding is to feed her up for a fat show. In verity, if this continues, the line between the show of "the Royal" and that of the Club will be a distinction without a difference. But the matter is not to rest here. Mr. Badham, of Suffolk, has declared his intention of moving, at the next Meeting of the Members of the Smithfield Club, that heifers or cows in-calf be not allowed to enter at the Christmas Fat Show; but that spayed heifers and martins be admissible. At present it seems, that the two latter are excluded. Another mooted question was that touching Mr. Heath's polled Scot, which was disqualified at Poissy as being a cross, and not a pure-bred animal. With praiseworthy resolution to have the charge thoroughly sifted, Mr. Heath reserved the animal for this Meeting, where he takes the first premium of his class against a well-known Scotch exhibitor. Surely this should settle the case. If Mr. Heath has fairly won at Smithfield, he is as clearly entitled to his place at Poissy. But he goes further than this. He has challenged his opponents to the proof, yea or nay; and none is forthcoming! During the week his friends have circulated a pamphlet containing the particulars and correspondence, which is unmistakeably all one way. A number of breeders and experienced judges have also signed a paper declaring that the beast looks like a pure Scot. Of itself however, this goes for little or nothing. An animal may to all appearance look thorough-bred, without actually being so. Some of the seemingly best Shorthorns at Birmingham last week were prevented from competing because their pedigrees could not be proved. We think, indeed, that Mr. Heath has clearly won his cause without the aid of such evidence as this. At the same time it is only right to say that the Editor of the *North British Agriculturist*, in his paper of this week, calls the *Times* to account for even now recording the beast as a pure Scot; and declares "the Jury at Poissy were furnished with documents which proved that the sire of the ox was a Shorthorn, and the dam a polled cow."

Turning for a moment from the Stock Show below to the Implement Gallery above, we find at once that the crowd is worse than ever. It is almost a question whether, with the present limited accommodation, agricultural machinery can still hold its place here. Despite a higher charge for less space, the entries both of stands and wares appear, naturally enough, to increase. The different articles were positively piled up one on the other, and a purchaser might quite as well buy from hearsay as from what he could see or test under such circumstances. Generally business was complained of as not being so good, although one or two prize firms of the present year drove a very thriving trade.

The week, as we anticipated, was altogether a busy one; and we must hasten to take a brief review of a few of the more important events to be chronicled in its history. The Monday was signalized by the presentation of THE NESBIT TESTIMONIAL, which, with the discussion of the evening, brought together a very large audience at the Farmers' Club. The amount subscribed approached very closely on the handsome sum of three hundred pounds, which was expended in a service of plate, with the appropriate addition of a valuable microscope. Mr. Nesbit subsequently lectured on "the mechanical and chemical principles which should properly regulate the practice of drainage;" the discussion quickly resolving itself into the comparative merits of deep or shallow. The turn appeared to be for some time all in favour of the latter, though a few good men came to the rescue of the four-feet system before the debate concluded. The resolution went to declare that much might be said on both sides; and, more definitely, that depth alone would never control width.

A full report of the Farmers' Club dinner will be found further on. It was satisfactory to see from the Report circulated that the Club never stood so well either in strength, funds, or influence. The Smithfield Club Dinner, of the day following, is also given. We never remember one so well attended; and if the members and their secretary, Mr. Gibbs, will only continue to break out a little beyond their conventional course, as successful a meeting may be annually ensured. What is chiefly to be feared is the stereotyped answer that "we have never done this or that before." In the unavoidable absence of the Duke of Richmond, Lord Berners took the chair, with every right, not merely from his own tastes and success in the pursuit, but as the President of the Royal Agricultural Society.

In this capacity his Lordship also presided at the General Annual Meeting in Hanover-square, on the Friday. This was the first year of bringing forward the meeting a day earlier in the week, and the experiment may be recorded as a successful one. The attendance was far better than usual. A lengthy discussion followed the reading of the report, during which another effort was made by a few malcontents to put the Society and its management in as bad a a light as possible. The number of members were declining—the accounts were badly kept—the country meetings did little good—and so forth. It turns out that the Council, in the exercise of the soundest judg-

ment, have struck off a great many names from their list, who would not, or could not, be made to pay up; and that in really good members—practical farmers and others of a similar character—the Society was never so strong as it is at present. Again, the only auditor present declared that the accounts could not be better or more clearly kept. We have heard the same over and over again from very many quarters, and we believe that in this respect Mr. Hudson and the Royal Agricultural Society might challenge any public body in the kingdom. Then, the country meetings do no good, but only raise a little temporary excitement! We fearlessly assert that if anything has tended to the advance of agriculture it has been these country meetings of the Society. And as to a little temporary excitement, it is well known that the effect of such a visit is never forgotten. The climax to all this came in a proposition bodily put, that all meetings for the future should be held in London! If any man wished to destroy the good of which such a society is really susceptible, he could name no other so suicidal a proceeding.

Still, in some minor matters let the Council take heed. For instance, let the Professors hand in their lectures for publication immediately on their being delivered; allow the Press to report the proceedings of the weekly meetings although we by no means pledge ourselves to record all that is said on these occasions. The fact is, and there is no denying it, that some people go here merely to advertise themselves. They even find fault in the furtherance of so laudable an object. Let us never forget what Mr. Acland said at Salisbury, when a very similar exhibition to what was witnessed on Friday took place:—"The Council should be careful to notice whence complaints really emanated. They were too often, with some people, but the excuse *to make for themselves a little petty importance, or to indulge in the opportunity of delivering a fine speech.*" How true all this is, many who were present at the meeting here will need not to be told. Let those who were absent picture a man without position or any authority as to what is going on, self-electing himself patron of the proceedings—greeting every sentence he approved of with an isolated "Hear, hear," and smirking and nodding at every speaker, lord or commoner, who got up. Assurance, no doubt, is a very fine thing, but surely it has some limit. Again we say with Mr. Acland, let the Council be careful to see from what quarter these complaints come.

The other meetings included one on the Thursday at the Freemasons' Tavern, when Mr. Halkett lectured on his new process of ploughing by steam. We shall return to the subject at some length hereafter, and to the pamphlet he has just issued —the fourth or fifth during the week on things agricultural. On the Wednesday evening, clashing as usual with the Smithfield dinner, the Society of Arts announced the reading of a paper "On the progress of the agricultural implement trade during the last twenty years." Fortunately, as it would appear, we were prevented, for the reason just given, from hearing this effusion. Our contemporary, *The Gardeners' Chronicle*, in manifestly a most charitable spirit, declares it to have been "a rather tedious account, deficient in point and interest." We have since had an opportunity of seeing the paper in the Society's "Journal." It seems to us to be a clumsy attempt to puff certain manufacturers, and as awkward a one to ignore others. So palpable was this, that a member rose on the first opportunity, to protest at the unfairness of such a course, and to name firms which had been excluded in so extraordinary manner from notice. Mr. Caird the chairman of the evening, at once stopped this, as out of order! But, in doing so, the honourable Member for Dartmouth must have surely forgotten the first duty for which a chairman is elected at all—to see and ensure fair-play.

Further than this, we can leave the prize lists and such reports as are worth giving, to speak for themselves. As a whole, the week's result must be regarded as a most encouraging one for agriculture. All the Institutions devoted to her cause are doing well, for the farmers themselves are taking more and more interest in them. In such hands would we cheerfully trust them. What is chiefly to be feared and guarded against is the interference of empirics and charlatans—whose only object is to create disaffection, and float themselves upon the troubled waters they may have raised. With Mr. Acland we say, once more, beware of them!

REVIEW.—MR. GIBBS' HISTORY OF THE SMITHFIELD CLUB.

Very nicely timed to the occasion, and in fulfilment of a promise made some time since, Mr. Brandreth Gibbs gives us his history of the Club. It is very well done. There is no attempt at fine writing; but with the best taste the author strings the facts before him together in plain wholesome English. It is, in fact, just the style for such work. The value of the essay, moreover, is made to depend essentially upon matter which Mr. Gibbs found at his command in the chronicles of the Club. From this he extracts and condenses with much judgment; while from the same source he is enabled to compile several sets of tables that will always have a value in the way of reference, and an interest for those at all taken with the pursuit upon which they turn. It is satisfactory to feel that this history could not have been in better hands.

Without in any way attempting to follow Mr. Gibbs through the succession of eventful changes that have characterized the progress of the Smithfield Club, we may still avail ourselves of a few points that at such a season must be more than usually acceptable. In the first place, then, as to its origin:—

"The national society now known as the Smithfield Club was instituted under the title of the 'Smithfield Cattle and Sheep Society,' Dec. 17th, 1798. Mr. J. Wilkes, of Measham, Derbyshire, the founder, and several other well-known agriculturists, assembled for its formation on that day, being the great Smithfield market-day before Christmas. The late Francis Duke of Bedford occupied the chair. There were also present, Lord Somerville, John Bennet, the Earl of Winchelsea, John Westcar, Richard Astley, John Ellman, Arthur Young, and twenty one others. Later in the same day eight more members, including Sir Joseph Banks, were added."

In some twenty years from this time the Club was supposed to have accomplished all it had aimed at achieving. Arthur Young had not only resigned the secretaryship, but had withdrawn entirely from the Club. The support of the country had not been afforded or continued to that extent the members expected. Accordingly, in December, 1821, the Duke of Bedford, the then chief patron and prop of the Club, not only retired, but at the same time discontinued the handsome sum he had for years been in the habit of giving in premiums. His Grace's letter in announcing this determination is

rendered chiefly memorable by the following passage in it:—

"The advantages which, on the first formation of the institution, we held out to the public have been amply realized, and that any further incentive to improve the breeds of cattle, sheep, and swine, *is become wholly useless*. The only object was to increase the animal production of the kingdom, and this object has been fully attained. The markets of the metropolis and throughout the kingdom are abundantly supplied; the best and most profitable breeds of cattle and sheep have been brought into notice, and have made rapid and extraordinary progress in the estimation of the breeder and grazier."

Fortunately the other members did not fall in with the Duke's opinion; but struggled on. The very next year the judges pronounced the Show to be one of the best ever witnessed. And, in short, the Club has never done so much good as from the time its President declared the incentive it offered to have become wholly unnecessary. If he could only have lived to see one of our gatherings of this present day! But the Bedford title is still one that will ever have a high place in the records of the Smithfield Club.

What a common, everyday question it is to be asked "Which is our best breed of stock?" "Which have really done best at our public shows?" And what answers you have, turning of course on the bias or prejudice of the authority you consult! Thoroughly independent of rank or person, let the Club itself for once stand as Sir Oracle:—

"The short-horns (oxen 10, cows 16) have won	26	*gold medals*		
The Herefords (oxen 9, cows 1)..	„	10	„	
The Devons (oxen)	„	3	„	
Cross-bred (cows)	„	2	„	
Whilst in the general *prizes*—				
The Hereford oxen have won	185	*prizes*	£2758	2
„ cows „	22	„	231	0
				£2989 2
The short-horn oxen „	82	„	£1399	5
„ cows „	92	„	1132	15
				£2532 0

"The result obtained is that the total number of gold medals is much in favour of the short-horns. This is chiefly owing to the short-horn cows having won the greater proportion of them. On the other hand the number and amount of general prizes are vastly in favour of the Herefords, their principal winnings having been in the oxen and steer classes, while the short-horns owe the fact of their approaching the Herefords at all, in total amount of winning, to the success of the short-horned cows."

Complete lists of all the gold-medal animals are given, for sheep and pigs as well as cattle. The most interesting deductions obtained from weighing the stock are recorded. The several alterations and additions to the prize sheet are methodically dated; and the names of all those noblemen and gentlemen who have ever taken an active part in the administration are classified in accordance with the offices they have filled. Information of this kind was much wanted; and we can well understand, while meeting but just once a year, "how little was generally known by the members of the History of the Club." For their especial benefit has their secretary thus employed himself; and to them, with his Grace the Duke of Richmond at their head, is his work dedicated. The offering, we repeat, is a most acceptable one. For agriculturists in general, however, it contains so much interesting information as to necessarily demand for it a circulation far beyond the few hundred members, over which it appears the Club has never extended.

BATH AND WEST OF ENGLAND SOCIETY.

An important monthly Council meeting of this Society was held, on Saturday, Nov. 28, at Waghorn's Railway Hotel, Taunton, John Sillifant, Esq., of Coombe, Crediton, in the chair. There were also present—Messrs. W. Porter, J. E. Knolly's, W. E. Gillett, T. D. Acland, J. Hooper, J. Gray, C. Gordon, J. Widdicombe, R. Smith, R. Dymond, G. Poole, D. Adair, R. K. M. King, W. Thompson, E. Vidal, M. Farrant, T. Danger, W. Wippell, R. May, J. Fry, H. G. Moysey, J. Belfield, J. D. Hancock, T. B. Morle, S. Pitman, J. Gould, &c.

Appointment of Veterinary Inspector.—The report of the committee appointed to consider the subject of the Veterinary Inspector was brought up and discussed. The committee represented that the services of Professor Brown had been retained on behalf of the Society in this department for the forthcoming meeting at Cardiff, in 1858; and the selection appeared to meet the unanimous approval of the Council.

The Implement Prizes.—Mr. Knollys presented the report of the committee, to whom the preparation of the implement prize sheets for the ensuing year had been entrusted. A report was presented with the implement schedule at the last monthly meeting, when the list was referred back for further consideration, and the same as now revised was received and adopted.

The Meeting of 1859.—A deputation from the inhabitants of Bridgwater attended with a view of urging upon the attention of the Council the great facilities presented by that town for holding the annual exhibition of the Society in 1859. In reference to this subject a communication was read from the promoters of a public meeting at Barnstaple, which, it was stated, was attended by the leading inhabitants and many of the influential landowners and leading yeomen of North Devon, called for the purpose of securing a proper reception of the Bath and West of England Society there, should the Council think fit to select Barnstaple for the site of the meeting of 1859. Mr. Smith, on behalf of the latter place, mentioned that active measures were being taken by the tradesmen of the borough and the agriculturists of the vicinity to give the Society a reception in every way worthy of its high character and importance. The decision of the question was, after some discussion, deferred to a future meeting.

Terms for the Cultivation of Land in the West of England.—The question as to the desirability or otherwise of the Society taking steps to secure a form of covenant between landlord and tenant, better adapted to the advanced condition of agriculture in the West of England, has been several times before the Council, and it was again introduced to-day, when, after a lengthened discussion, it was resolved on the motion of Mr. Charles Gordon, seconded by Mr Knollys, "That a committee be appointed to consider whether the Society may, with advantage, prepare some suggestions of terms for arrangement between landlord and tenant for the cultivation of land in the West of England, which may be suitable to the advanced state of agriculture, and to consider other subjects connected therewith, which may tend to promote its further progress."

The Cardiff Meeting.—Two members of the Council—Mr. Jonathan Gray and Mr. J. Widdicombe—were authorized, on behalf of the Preliminary Committee, to enter into the various contracts necessary at the meeting at 1858, and requested to report the same to the Council Meeting in January.

New Members.—The undermentioned gentlemen were elected members of the society: Mr. Frederick May, *Courier Office*, Taunton, Somerset; Mr. Winter Gibbs, Taunton, Somerset; Mr. Frederick Knowles, Wrington, Somerset; Mr. Williams, Barnstaple, Devon; Mr. Francis Trood, Netherexe, Devon; Mr. T. Goldie Harding, Halsannery, near Bideford, Devon; Mr. C. Roe, Lynmouth, Devon; Mr. W. Hemming, Coldicott, near Moreton-in-the-Marsh, Gloucestershire; Mr. H. Entwistle, Llanbethian, Cowbridge, South Wales.

THE TRIALS OF THE STEAM-ENGINE.

Suggestions sent by Implement-makers and Judges.

TO THE EDITOR OF THE MARK LANE EXPRESS.

Sir,—I beg to acknowledge the receipt of your letter respecting "Certain correspondence from the Royal Agricultural Society, on the subject of Steam-engines," which you are publishing, and think your offer to contributors most liberal and fair. I did not give any opinion in the matter of the society's circular, but being very much dissatisfied with the trial of implements at Salisbury, and hay machines in particular, I took the opportunity of addressing the secretary on it, and beg to enclose a copy of my letter to him. I know not whether it may have any result with the implement committee. I leave it with you to do as you please, and should be glad to have the name of your agent in Bury.

I am, Sir, your obedient servant.

W. Wyatts.

Hardwick House, Bury St. Edmund's, Nov. 25th.

TO THE SECRETARY OF THE ROYAL AGRICULTURAL SOCIETY.

Sir,—I have been favoured with your circular to the Royal Agricultural Society's implement exhibitors, together with a minute of the society's council, "inviting the respective opinions of its implement makers in reference to a revision of the conditions affecting the construction of steam-engines and other machinery to be exhibited for trial next year," the importance of which has been brought to the attention of the council by Messrs. Shuttleworth and Howard.

I am not able to give any opinion on this subject, not well knowing the existing conditions or their bearing. I hope, however, if they are revised they will not become more exclusive by it. But, Sir, I am anxious to address you and the committee on a part of the society's affairs, of not less importance to a certain class of its exhibitors, and I hope I may be allowed to do so on this occasion.

I wish to draw attention to the defects of the rules and management under which competitive trial of field implements for prizes is conducted, and under which, I respectfully submit, that general improvement and "fair trial" contemplated by the society is not attainable.

To be brief in explanation, I refer to my own work. I entered a hay machine for competitive trial at the meeting in July last, under the impression that all field implements would be severely tested as to their weight and resistance to draught. I had found the best modern hay machines heavy in these respects, and thought I could improve on them, simplifying at the same time. My implement is original in all its parts and adjustments, the work of years under private trial. I reduced the working parts thirty-seven per cent. as compared with the machine that took the first prize at Salisbury, and reduced from forty to fifty per cent. in weight as compared with that machine, without giving up strength. The difference as to the resistance I had no means of knowing. I made other important improvements, which practical men thought worth a patent. If my work had any merit it went for nothing, from a defective mode of trial. To my great disappointment there was no test of the weight, or of the power required to draw any implement whatever. There was nothing about it in the rules or in practice. I consider this a very great defect, and that those tests ought to be the ground-work of the trial in all field implements. Practical farmers know it is of importance whether any particular implement is seven or twelve hundred weight. Whether it may be drawn by a pony or from its weight or principles of construction, it may be too much for a heavy horse, but they can draw no information on those points from the society's prize trials. They are left to find it out in their own fields. I wonder at this. The judges walk in the dark with the rest. They draw no light from the rules, which ought to guide them. The worse machine may do its work as well as the best at such a trial. The only way to inventive improvement or excellence is shut up, and competitive trial does more harm than good.

Another great defect at the trial of hay machines and horse rakes at Salisbury was, the insufficiency of ground for them. I suppose this was the fault of management. I think this also ought to be subject to some rule. The ground was only enough for two implements, instead of ten or twelve. Marking out a piece for each was not attempted, it was not practicable on half an acre. Once or twice up and down the piece was all that could be afforded, one machine throwing the grass in on the ground to be gone over by the next, the horses often trotting rather than walking, which would disqualify under proper rules. I have been working these machines for thirty years, and have brought some experience to their use and construction, and I assert respectfully that their merits and capabilities respectively are not to be brought out in this way, and that I consider the trial of them at Salisbury unworthy the Royal Agricultural Society.

It is my wish to address this to the proper quarter, with a desire only of fair play, and the general improvement, my interest otherwise being little affected. I think I have pointed out faults, and that they are most easy of cure. I hope, therefore, you will think the subject worthy of being brought before the committee, and hope also the decision on the question to be soon before it on steam-engines, &c., may be made known to the society's exhibitors.

I am, Sir, &c., &c.

To James Hudson, Esq. W. W.

October, 1857.

I received for answer that the above would be laid before the committee, which was to meet on the 3rd of this month.

TO THE EDITOR OF THE MARK LANE EXPRESS.

Sir,—In common with other exhibitors, we were requested by the Council of the Royal Agricultural Society of England some time since to furnish them with our opinion, and to offer any suggestions we might think advisable upon the method employed to test the capabilities of the different implements exhibited at their annual shows. A variety of circumstances caused us, quite unintentionally, to overlook the prescribed period for doing so; we, therefore, take the liberty of offering a few observations on the subject, trusting you may find them of sufficient importance to give them a place in your valuable columns.

The first remarks we have to make will be upon portable engines. It is unnecessary for us to remind you that the primary object the Council had in establishing prizes for them was by testing the engines of various makers to be in a position to guide the decision of farmers and the public as to which were the most serviceable, and the best adapted for the purposes of a farm, and therefore most fit to be placed in the hands of an ordinary farm-servant. So far so good; but the annual testing of these engines, and the great stress laid by the judges upon the consumption of coal induced all the first-class makers to depart from the ordinary commercial engine they were in the constant habit of making, and to construct one whose especial purpose would be to effect that economy without regard due to other points—such as simplicity of parts, strength of construction, &c., so that the trial engine would bear about the same likeness to its commercial brother in point of simplicity that a chronometer would bear to a common watch. Tubes were multiplied to three or four times the surface of an ordinary engine, their thickness reduced to 16 to 18 in. wire gauge, and the spaces between them to $\frac{3}{8}$ or $\frac{1}{2}$ in. Further expansion valves were introduced as well as water-heaters, and all this for the simple object of economizing the fuel in the hope of securing the society's prize. This description of engine we have known to cost the makers £200 more than the ordinary kind, while this large expense has been incurred not to produce a more serviceable engine, not to produce a stronger one, not to produce one more calculated for

the work of a farm, but an engine that might save a few pounds of coal per day; while from the delicacy of its adjustments, its extreme complication, and number of parts, increased number and slightness of tubes, and diminished water-spalls rendered it much more likely to derangement. The effect of this decision is, that the farmer says to the Royal Society, "Gentlemen, let me know which is the best engine." The Society answers, "So and so's is the most economical engine;" and therefore the prize one, and the unfortunate farmer buys an engine from these makers which has nothing in common with the prize engine except a boiler, a cylinder, and travelling-wheels. For these considerations, therefore, it is that we think that most of the observations made by the different makers to the Royal Society miss the mark, and that their attention should be directed to ensure a supply of fair commercial engines rather than to the details of the trials, which we consider to have been performed with the greatest care and exactitude by the judges. As a remedy for this serious difficulty, we beg respectfully to suggest whether the Royal Agricultural Society of England could not cause each maker or exhibitor of engines to sign a declaration to the effect that he the exhibitor on his honour declares the engine entered to be a *bona fide*, fair, commercial engine, that the evaporating surface amounts to — feet per horse-power, that there is no water-heater, nor extra expansion valve, and that he is ready to supply an engine similar in every respect to any purchaser at his catalogue price. On the other hand, if the Royal Agricultural Society of England can prove that a false declaration has been made, the Society after investigating the circumstances shall prohibit him from ever exhibiting at any of their future shows. We do not think that the society should take upon itself to lay down certain propositions for boilers or steam-engines, as that would have the effect of preventing any further improvements; but we do think they should take every possible means of preventing a racing engine being entered; and we would further urge that in case of any departure by the maker or makers from their ordinary engine, such improvements should be described in their declaration, and they should be able to add that for the future they mean to construct all their commercial engines with such improvement or improvements. We have said before that we have every confidence in the correctness of the trials; we should, however, suggest that the coal, of whatever description used, should be broken up in lumps the size of walnuts, and screened free from dust, and that it should be afterwards weighed out to the different competitors.

Respecting the trial of steam-thrashers, we have only one observation to make, viz., that we should suggest the weighing of the sheaves to be thrashed instead of counting them, as it is well known that the same field very often varies 25 per cent. both in the length of the straw and in the quantity of grain yielded; and, after all, the surest test of the working of a thrashing-machine is the quantity of straw passed through it in a given time, and clean thrashed, and not the quantity of grain. We also think that the trials should last during one-half hour for each machine.

With respect to the other machinery trials, we think that the general principles laid done by the Society are sufficiently guarded to ensure a pretty accurate result.

Hoping you will excuse the length of this letter, and that you will have the goodness to insert it in your next,

We are, sir, yours respectfully,

BARRETT, EXALL, AND ANDREWES.

Kates Grove Iron Works, Reading,
Nov. 27, 1857.

TO THE EDITOR OF THE ENGINEER.

SIR,—Your agricultural contemporary, the *Mark Lane Express*, is publishing a series of suggestions made to the Royal Agricultural Society by a number of engineers and implement-exhibitors at the Society's shows, for the future conditions for trials of steam-engines, threshing-machines, &c.; from these suggestions have arisen the remarks which I now beg to enclose you, and shall have pleasure in seeing the same in your scientific columns if you consider them worthy of a place there.

"Adjudication should be represented by points," say Messrs. Ransomes and Sims, and say also Messrs. Garrett and Sons, and Mr. B. Samuelson, in their suggestions to the R.A.S. relative to the forthcoming trials of steam-engines and threshing-machines, at Chester, as published in the *Mark-lane Express* of November 16th; whilst Messrs. Brown and May, John Gray and Co., and Tuxford and Sons, in their suggestions leave out of consideration the question of points altogether. Messrs. Ransomes and Sims, and Messrs. Garrett and Sons, give certain divisions of points, each in the same rotation, with the exception of the third one, which Messrs. Garrett omit. This conformity of views gives evidence of some previous conference or correspondence between those two firms, and hence these points must not be set down as hasty remarks, but as matured ideas leading to some desired result—say,

	Ransomes and Sims.	Garrett and Sons.
1. Durability to count..	20 points	10 points.
2. Simplicity	20 „	10 „
3. Excellence of material and workmanship..	20 „	— „
4. Consumption of coal.	20 „	8 „
5. Portability	10 „	6 „
6. Price per horse-power	10 „	6 „

In reasoning upon this subject of points, we must first ascertain if perfection or any proof positive can be arrived at, as the index to count from: if not, then the system is false, and no satisfactory results can be obtained. With the threshing machine, the straw may be so closely examined as to determine whether it be threshed clean or not, whether it is clean shaken or not, and what power has been absorbed in threshing a given number of sheaves. These and other determinate results may be obtained with the threshing machine, and are true standards upon which to establish a system of points. But with the steam-engine, what in a trial is to determine "durability"? what "simplicity"? what "excellence of material and workmanship"? Such as is sent out from the factory to the purchaser, not that which is merely sent to the agricultural shows?—"Consumption of coal" can be determined, and the power obtainable from a given quantity established; the judicious arrangement of boiler and furnace can be proved by the evaporation of a given quantity of water with a given quantity of fuel, in a given period of time.—"Portability," what is to determine it? Shall simple lightness of construction, at the hazard of explosion, be the guiding star here? or is this to be determined as a quality in combination with something not expressed? And "price per horse power," is it not with engines as with horses?—whether worth £5 or worth £50, a horse is still a horse; or whether inferior or excellent, an engine is an engine. But unfortunately, in the proposed points the superior engine, because more costly to produce, would lose its points; while the inferior engine, through its less price, would count so many points towards a prize!

Here, then, we have amongst all these heads for points but one that can be brought to a determinate result, and that is "consumption of coal;" and is it not upon this result in trials of steam-engines that awards should be made? Is not fuel the *primum mobile* of the steam-engine? and is not the most economical use of it the great desideratum with practical engineers? Will not the excellency of results prove the excellency of the mechanical combinations for producing these results? And does not this simple, clear, and accurately-definable test of fuel, close the door against all charlatanism, and specious reasoning under the cloak of "points;" beneath which garb, engines doing but inferior duty would be brought before the world with first-class reputations? B. C. E.

Nov. 18th, 1857.

A PLAIN FARMER'S VIEWS OF THE NEW THINGS IN AGRICULTURE.

I have, as briefly as I knew how, noticed the steam ploughs lately introduced to the agricultural world. Besides these so-called ploughs, we have various other inventions made to aid in cultivation: these are upon the rotary principle. The only one drawn or impelled by steam, which I have actually seen in work, is Usher's steam plough. This I saw at Carlisle. It is a ponderous thing altogether. A powerful steam engine precedes a large revolving cylinder, or cylindrical framework, upon which are affixed a number of plough bodies, or rather ploughshares in frames; and as each share comes down in contact with the soil, it penetrates or presses into it, and turns over with more or less accuracy a furrow a few feet in length. The slight trial given to it there sufficed to convince me that it was a great waste of power for a very ineffectual purpose. The idea of every share having to descend to enter the soil independently, and turn over a small length of furrow, and then to rise again, and so on in succession, one after another, leaving little strips after the engine, I felt assured must be an erroneous one, and could never be brought into general practice. The result has proved my view correct; for we never hear of it now, so I presume the scheme is given up, or, at all events, laid aside.

One almost wonders what will come next; and to find so much thought, ingenuity, and capital expended upon manifestly erroneous principles, astonishes every plain farmer. I like the plough: it is near perfection: we only want to establish economical draught-power. I believe it will be a long time before it is superseded, even by our friend Mr. Smith; but revolving ploughs around a large drum I don't believe in. Far better, in my humble opinion, is the principle of rotary cultivators, of which, however, I have not yet formed any very elevated opinion. I will now notice some of these very briefly. I have more than once seen Samuelson's digging machine in work. Gibson's I have also seen in work. Both pulverize very well, so far as they go; but it requires the power of four good horses to break up even a less breadth than two feet. Both machines work upon a similar principle — having revolving teeth or forks. Samuelson's are like fork tines, and are made of steel. They revolve very rapidly, and break up the soil to six or eight inches deep, throwing out behind a continuous stream of pulverized soil. Gibson's is a series of cast-iron wheels with strong prongs. These press into the soil, which is pulverized as it is turned up. This machine is, however, better adapted for clod-crushing rather than breaking up the unploughed soil. Samuelson's can more effectually break up such soil, bnt at a great expenditure of power. The most important implement of this class with which I am acquainted is Romaine's patent steam cultivator. I have not seen this machine in work, therefore cannot offer any personal observations; but from reliable information given me by a close observer who recently inspected it, I am inclined to think there is something really valuable and of considerable utility in the invention. It is the same machine upon which our worthy pioneering friend Mechi some time ago staked, or offered to stake, his agricultural reputation. It is said to "differ from all others hitherto brought before the public for the purpose of applying steam-power to the cultivation of the soil, in entirely dispensing with the use of ploughs, ropes, or auxiliary implements. It is a fourteen-horse portable steam-engine capable of propelling itself, combined with, and giving motion to, a rotary digger." The engine and boiler are carried on a pair of high broad wheels, with two small wheels in front. The large wheels are driven by the engine; the small wheels are used for steerage. By a simple disengaging arrangement the latter are left free when the machine has to be turned round, and by driving one of the large wheels, while the other remains stationary, the implement can be turned completely round within its own length. The cultivating part consists of a hollow cylinder six feet six inches long and two feet six inches in diameter, armed with cutters made of wrought-iron, of sufficient strength to enter the soil. These are separately secured by bolts, and can readily be replaced in case of accident. In work, it takes six and a-half feet, which it highly pulverizes; and it can be turned on the headland in less space than the common plough with two horses abreast. Its daily work is about six acres, at an expense of 35s.; and the depth taken from seven to nine inches. It digs the ground, besides pulverizing it; so that at one operation, it is said, the work of two ploughings and an indefinite number of harrowings is performed, whereby a good seed-bed is obtained. Now, to me, this does seem more like a really useful implement; and if it can be made to do all this work effectively at a moderate cost, it cannot fail to be a great boon to the farming community. I heartily wish Mr. Romaine, the inventor, and Mr. Crosskill, the manufacturer, every success with it; and hope they will soon bring it before the public openly, so that its merits may be well looked into.

Just a word about rotary cultivation. I am a plain man of business, and look to have my work done properly and effectually, so as to save the necessity of resorting to adventitious aids to accomplish my purpose. With a strong iron plough and a good team, I can plough and thus break up *my land* in its driest, hardest state. No cultivator that I have seen can do this. I am to-day, in my latter-seeding, ploughing-in a luxuriant growth of green oats and annuals, which constitute in this most prolific season a regular green manuring. There it lies under the broken furrow, where I hope it will do my crop good service. These rotary cultivators would throw it on the top, making a pretty mess—stopping harrows and drilling, and leaving a most unsightly field. In all cropped lands there are corn roots, stubbles, &c., &c., to be ploughed in, there to rot upon the furrow-sole, to be mingled in the next operation of culture. The rotary cultivators attempt to mix all as they proceed, but don't do it; and the value of rotting roots, stubbles, and other vegetable matter, is chiefly lost or passes away. The mingling must have time, the decaying process must have time, and the decaying matter must be arrested and retained in the soil. I am one of those untidy farmers whose farms will, somehow or other, produce twitch; of course it is indigenous—it grows, it will grow. Well, there it is. My ploughs break it up, in ploughing, in something like order; and it is brought up, in the next process, as a sod or lump, and is easily "picked." These rotators tear it all into bits, which on my cool light soils will never die, and not readily on the heavier portions of my farm; there it lies, forming innumerable sets for future plants. Well, enough of this; for one might go on indefinitely. I must say that I am old-fashioned enough to prefer that old time-honoured implement the plough, in some one or other of its now almost innumerable phases, as the first

motive power for breaking up the soil. I like that partial inversion of it; I like that simple, gradual, gliding process of upturning the furrow; I like that simple combination of artistic power so admirably shown in the ploughshare and mould-turner—the gradual lever-lift, the inverted Archimedian screw, gently pressing over the soil at the most acceptable angle. I much question if any implement will ever be invented requiring less draught power in perfecting the same work.

To Mr. Hemming.—I am obliged by your correction. My full conviction still is that fourteen tons was given to me as the weight of the engine, which of course would include water; and I much regret if I have made a wrong statement.

NOTES ON NOVELTIES AT THE AGRICULTURAL SHOWS OF 1857.

THE GLASGOW MEETING OF THE HIGHLAND AND AGRICULTURAL SOCIETY OF SCOTLAND.

Of this, confessedly the most successful of all the Society's meetings, the feature which at once claimed the attention of the English visitor was the mode of classification of the implements and machines contributed. For agricultural shows there are two modes of classification eligible: first, according to the kind of work to be performed by the implement or machine; second, giving a certain amount of space to each individual manufacturer, allowing him to arrange his contributions as best he thinks fit. Of these two modes the first is the philosophical; the second, the commercial; and they are to be judged of from entirely different points of view. If the object of the Show is to facilitate the farmer in making comparative observations of the different machines, and to serve some important points in agricultural education, there can be no doubt that the first mode is in every way the best. If, however, it is considered essential to consult the commercial interests of the exhibitor, and, to facilitate his obtaining orders, to create a sale for his wares, the nearer the approach is made to the character of a bazaar the better. It is simply a question between the farmer and the implement maker, as the buyer and the seller, and whether it is politic to study the interests of the one more than those of the other. For purely agricultural purposes it is evident that the first classification is the best; for it is obvious enough that, of any machine which the farmer is wishful to purchase, the more specimens—that is, of different makers—he sees, the better. A thoughtful walk through what may be called the confusion of Salisbury and the well-ordered philosophical arrangements of Glasgow, would have soon made this clear to any one previously doubtful of the truth of the position. Not, let it here be noted, that we are carping at the arrangements of the Salisbury Show—they were admirable, so far as the system of classification adopted admitted of; we simply wish to show that where a farmer was desirous of comparing the arrangements and workmanship of a machine brought out by one manufacturer with those of others, before he could go from one place to another, hunt up specimens, and examine the peculiarities of each, all data for comparative observations would have evaporated from his brain. Few mechanics could effect the object—how could we suppose farmers to be successful? The Judges adjudicating the merits of each implement are not thus expected to wander from stand to stand—at least if they do, their judgment will fail in some particulars; and every farmer would undoubtedly be the better if the shows enabled him to have the facilities of the Judges. It is for the Societies to say how far in this way they wish their shows to be truly educational institutions; nor would this facility of making comparative observations be prejudicial to the interests of the manufacturers themselves. We can easily imagine some, who to crude notions of arrangement add imperfection in workmanship, objecting to this facility of comparison being afforded to the buyers; but we have some difficulty in understanding how those who sell the best machine of any class fear competition. In truth, we do not think that this fear exists amongst our celebrated manufacturers—it is their truest interest and wisest policy to court comparison; at the same time, before closing our remarks on this subject—not altogether without its importance to the agricultural world—it is but right to mention that the system of classification adopted by the Highland Society does entail a hardship on those manufacturers who are desirous to do a trade at the show—as who of them is not?—in forcing them to have either an assistant at each separate department to explain to inquirers *their* machines and implements there exhibited, or, failing this, to allow them to remain unrepresented altogether—an alternative which *no business man* likes to be forced to adopt. This is a grave difficulty, and it is difficult to see how it can be overcome.

As the object of our paper is to take notice of the novelties chiefly at the various shows, not to give a report newspaper fashion, we have under the present division but little to say; for numerous as were the machines represented, many of them either presented the stereotyped features which are seen at each successive show, or where new, have been already described in the first part of our present paper, or in the paper given in the number of this Journal for March last on the Novelties of the Smithfield Club Show. For the purposes of this paper we deem it best, therefore, to take the classification adopted in the prize list as officially announced, and describe the peculiar features of the novelties of such sections as we consider it necessary to notice.

In Section 4 (Subsoil Ploughs for Moor or Strong Land, for three or four horses), Mr. Bentall took the first prize of £4. This implement, although no novelty to the English reader, may be so to some of our Scotch readers; we therefore give a slight description of its peculiarities. One form of it has three shares, preceded by three points, arranged parallel with each other; the centre share and point project beyond the two others, this arrangement enabling the implement to penetrate the hardest soils, and gives it a steady motion. It is mounted on three wheels, by which the depth of the work is regulated: the central beam, to which the centre tine is fitted, has two cross arms, each of which carries a side tine, the side tines having a lateral adjustment given to them as well as a vertical. By this arrangement the distance between the side tines and the centre one is increased or decreased so as to take in a lesser or greater width of land. The width usually covered is 3 feet 6 inches.

In Section 10 (Consolidating Land-rollers), Mr. William Cambridge of Bristol took the first prize of £5 for his patent self-cleansing clod-crusher. This

implement has a high reputation in England, and consists of a series of press-wheels on a central bar; each wheel has a slightly eccentric motion on the bar, and the wheels are made alternately large and small.

In Section 28 (Liquid Manure Distributing-Machines), Mr. Isaac James of Cheltenham took the first prize of £4. The liquid in this machine is forced through a distributor, which gives a shower capable of covering from 10 to 15 feet wide. The joints are all waterproof. The valve is prevented from choking by the employment of a double strainer through which the liquid manure is made to pass before it enters the body of the cart.

In Section 29 (liquid manure pumps), Mr. David Falconer, Causeyside-street, Paisley, took the first prize of £2. The arrangements of this pump are simple and ingenious. The two pump barrels, so to speak, are formed of tubes of vulcanized India-rubber, and are made to collapse and extend alternately by the reciprocating movement of a beam.

In Section 30 (straw cutters for hand labour), Messrs. Richmond and Chandler, of Salford, took the first prize of £2. This machine is remarkable for the simplicity of its arrangements, its compactness, and for the excellence of its workmanship. By the use of toothed rollers, instead of the fluted ones generally used in straw cutters, the apparatus is nearly self-feeding.

In Section 41 (root washers), the same firm took the first prize of £2. To the back of the trough in which the cylinder containing the roots to be washed revolves, two curved racks are attached, one at each end. These extend beyond the machine. When the handle of the cylinder is turned in one direction, the cylinder continues to revolve in the trough, washing the roots. When they are judged sufficiently clean, the cylinder is caused to revolve in the opposite direction, when the toothed wheels at the end of the shaft take into the teeth of the curved racks, up which the cylinder climbs, as it were, and delivers the potatoes. When empty, it rolls down the rack to the bearings in the side of the washing trough.

In Section 42 (steaming apparatus), Messrs. R. and W. Smith and Co., of Eglinton Engine Works, Glasgow, took the first prize of £5. This apparatus is exceedingly compact in arrangement, and complete in its details. The boiler is on the Cornish or internal-flue principle, and constructed specially with a view to economize fuel.

YORK MEETING.

This, the twentieth meeting of the Yorkshire Agricultural Society, from its splendid show of stock, and its admirable collection of implements, proved itself no mean rival, in bidding for public favour and attention, to the Royal Society's show at Salisbury. From a good authority we learn that, at the society's nineteenth meeting, last year, £800 in prizes, besides gold and silver medals, were awarded, £200 of this being given for implements alone; the amount of the Royal Society, for the same class, at Salisbury this year, being only £173. The Yorkshire Society had at its show 700 implements—less by 180 only than the number exhibited at Salisbury. While at the latter show 154 exhibitors met, at the Yorkshire show there were no fewer than 93. But in stock the Yorkshire show bore off the palm: for, while at Salisbury there were only 151 horses, at the Yorkshire show there were 177; for 109 shorthorns at Salisbury, there were 100 at the Yorkshire show; while of poultry 220 entries were made, against 156 only at Salisbury. Certainly, this society owes no little to the district in which it is held, with a population of little short of two millions, noted for their enterprise in trade and commerce.

With reference to the implement department of this most important show, the two great features were the competition for the steam cultivation and the reaping machines. For the former the prize was announced in terms which, from their explicitness, contrasted favourably with the announcement for a similar prize competed for at Salisbury—"For the best application of machinery impelled by steam power to the cultivation of the soil, £30." But, still further to remove all doubts as to the comprehensiveness, and at the same time the precision, of the results aimed at, as regards economy of working, the following note was added: "N.B.—It is essential that the operation performed by this cultivator, whether it be disintegration or complete inversion of the soil, be accomplished at less cost than similar or equal results can be obtained by horse or manual power, and that the work be also as well done by the former as by the latter agencies." In competition for this prize, which thus included steam ploughs, rotary cultivators, and digging machines, two entries were made—namely, by the Patent Traction Engine Company (Boydell's endless railway), and by Mr. Fowler. Mr. Fowler's apparatus was not brought forward, so that the only apparatus tried was Mr. Boydell's traction engine. Being engaged at Glasgow, we could not get forward to York in time to witness the trial of this machine. We understand, however, that the work performed by the engine dragging Coleman's scarifier—taking a breadth of 7 feet 9 inches, and a depth varying from 5 to 12 inches—was, on the whole, satisfactory. While working with four iron ploughs, which were afterwards used, the crank of the engine broke, and put an end to the experiment, which, from all we can learn, seems to have been the most successful yet attempted with this form of traction engine.

For the reaping machine prize three competitors entered—Mr. Palmer, Mr. Wray, and Mr. Busby. The machine entered by the latter was that of Messrs. Dray—Hussey's improved, with tipping platform. The principal peculiarity in Mr. Palmer's "Union" reaper is the side and back delivery. This is effected by the use of a radiating platform at the back of the machine; the floor of this platform being composed of a series of rollers, those being of larger dimensions at the outer than at the inner extremities. The two outward rollers have a rotary motion given to them. The attendant, sitting on the machine, uses a rake, with which he draws back the cut produce from the front of the machine on to the receiver board, and the first of the set of rollers. On the line reaching the last rollers, which have, as above stated, a rotary motion given to them, it is taken on by them, and delivered to the ground in a line parallel, or nearly so, to the line of draught. A steel separator precedes the cutters, and, jointed to the side opposite to the working gear, it marks the division in the standing crop between the portion to come under the operation of the cutters and that left for the return of action. While passing over the platform, the corn is retained till it is delivered to the last rollers by a light fence. This is supplied with a roller, which facilitates the passage of the corn over its surface.

The peculiarity of Mr. Wray's machine is, that it is worked with one horse only. The inventor has aimed at making all the parts light, and moving the knife slowly. The knife is an endless one, revolving freely from under the back of the machine.

In the show-yard we noticed one or two novelties only. Amongst these the compact portable gas-making apparatus of Mr. B. Sanders, of Layerthorpe, attracted our attention. Gas can be made by it without much trouble, at the cost, it is said, of 1s. per thousand cubic

feet. This, we should think, was an under-estimate. The whole apparatus takes up little room, and its arrangements seem simple enough to be managed without difficulty by any farm-servant. The inventor has fitted up nearly 300 apparatuses in different parts of the country.

On the stand of Mr. Buxton (Malton, Yorkshire) we noticed a patent mill for breaking, splitting, and grinding oats, peas, &c. In this there is an ingenious adaptation of an Archimedean screw in the shaft which carries the grinding part. The screw is immediately beneath the hopper which supplies the grain to be crushed, and carries it to the grinding surface, over which it is distributed at an equal rate, so that if the mill is running fast or slow it cannot choke. The grinding part is formed of a cone divided into three sections; the first of these conical sections is provided with a series of coarse-cut segments, adjustable by means of set screws to fit them for breaking, splitting, &c. The second conical section is smooth in its periphery, but is provided with a series of ribs forming a screw, which carries the substances broken or split by the first cone up to the action of the third and last cone, over the surface of which they are distributed equally by the action of the screw cone. A current of air is also projected over the surface of the last cone, through the medium of the screw cone. The last cone is provided with fine-cut segments, which grind the substances split by the first cone into meal. A 12-inch mill will grind by power from 10 to 14 bushels per hour. The cost of a machine of this size is £12 12s. We understand that the manufacture of this machine has been taken up by Messrs. Richmond and Chandler of Salford, Manchester, whose well-known mechanical abilities will doubtless result in making it a machine of first-class workmanship.

Many of the machines and implements which presented features of novelty were also exhibited at Salisbury; and as we have already described their peculiarities, we have now little more to do, in concluding our brief notice of the Yorkshire Agricultural Society's Show, than to thank the Secretary, J. Hannam, Esq., for so courteously throwing all facilities in our way for inspecting the implements exhibited. — *Journal of Agriculture.*

THE EAST KENT AGRICULTURAL LABOURERS' ASSOCIATION.

SIR,—The vignette of your journal—an able engine, inscribed "*The Mark Lane Express*"—is a happy emblem of the work you have in hand. Deep-draining, long leases, improved machinery, chemical composts, agricultural progress—steps in advance, upwards and onwards—whatever may benefit the soil or its intelligent fertilizer, be he master or man—these are your aim. Your locomotive runs out, and brings back every passing incident of importance to agriculture, without prejudice of matter, distance, or country from whence you fetch your readers' information.

This is the more welcome at the farmer's breakfast-table, inasmuch as there is but little to tempt him out just now. A December morning is seldom pleasant—the "foracre" is so sodden, the air so raw, the fog so solid—as the early rooks cleave it with their wings—our whiskers so wet with the pride of the morning. Almost the only sound to cheer a farmer's heart in December is that which one would, at first, take for a couple of self-hunting puppies, but which proves to be "Yex," "Beam," "Chep," and "Scroad" of the Kentish plough in musical striving and labour together, as the crazy "turn-wrest" comes again to the straining of the smoky team and the crack of the ploughboy's whip.

Will a whistle from behind a Kentish plough interest any of your readers at this time?

Let it be known, then, since country practices differ, that the complete working establishment on a farm, say of five hundred acres, in East Kent is five teams, with a man and his mate to each of them. These ploughmen may be occasionally married men, but the majority of them are single. These are "farm-servants" in East Kent, in contradistinction to the ordinary "labourer" on the farm. It is calculated that this class of "farm-servants" in the eastern division of the county alone must amount fully to 5,000. This class has been hitherto mainly without education, and sadly ignorant of the merest elements of that inward hope on which their eternal destiny hinges, when ploughing and farming shall be over for ever.

There are things enough in *this world* that move us! For example, it touches the heart to the quick when, trebly cased in wool and waterproof, warm and snug, dry and well fed, the cold rain beats mercilessly down, and you pass on the road a mere child (one of the 30,000 employed in agriculture in England)—laying in the first seeds of a rheumatic old age, if not of earlier consumption—rook-keeping! Saturated with the storm, he drags one foot after the other, heavy laden with wet earth, to dislodge a sable trio, who only mock his misery and childish struggles by sweeping jauntily over his head, down-wind, and challenging another toilsome pilgrimage to the opposite extremity of the hundred acre field. No shelter for this child—no "tempering of the breeze for this shorn lamb!" His only interlude till the daylight closes in is his little dinner, to be eaten wet and cold; then more rain, and more rooks, till at last his day is done. This tears one's heart-strings. Surely there should be provision for these lads against the weather in every instance.

But this has its end; *moral* evils have no end—their influence is for ever.

With a lively appreciation of this last sentiment, the fact is an unwelcome one, that the class of whom we are now speaking *have been*, for the most part, habitual absentees from the house of God.

Was there any cause for this, operating upon this class more than upon others?

The inquiry suggested itself; and there appeared, on investigation, a long-standing custom upon the farms of East Kent, with some few exceptions, of "baiting" farm-horses on the Sabbath, from 10 to 12 a.m. (the hours of divine service in the morning), and from 4 p.m. (half an hour before the afternoon service is ordinarily concluded) to 6 p.m.

Here, then, appeared at once an insuperable barrier, in the shape of a custom, to the possibility of these 5,000 men and boys worshipping God at all on the Sabbath, if we except a limited number, who, having the "will," found the way by mutual arrangement of relief in Sunday-work.

In October, 1853, attention was first called to the existence of this custom, the injurious tendencies of which were not, indeed, wantonly sanctioned by the farmer, since it had crept insensibly into his establishment as a "custom received from his fathers." The first furrow being turned up, other things long existing—but existing also for the same reason unobserved—came, one by one, to the surface of inquiry. These were met by the immediate and honest acknowledgment of the farmer, and by his willing co-operation in desiring their removal or alteration.

Amongst these may be mentioned—

1. The yearly renewal of service between master and man, so subversive of any mutual interest and sympathy between the two.

2. The usual mode of access to the farm-servant's bed-chamber, viz., by a ladder from without-doors, giving opportunity for nightly excesses and absence, thefts and other irregularities.

3. The want of domestic comfort in the farm-servant's bed-chamber, want of water and washing utensils, of clean bedding, &c., together with excessive crowding in some instances, and commonly two men in a bed.

4. The general absence in farm-houses of any common

room, with a fire and candle in winter, as a place of rest, retirement, or quiet occupation, except the stable and bedchamber.

5. To these may be added the neglect of insisting on some satisfactory character (and especially a written one) on the hiring of farm-servants.

Here were many undesirable things, but all more or less easy of remedy. It was determined, however, to aim first at the reformation of that custom, already noticed, which left such a ready excuse on the lips of every farm-servant for neglecting his religious duties on the Sabbath-day. "I have no time for public worship," said he; "I am called during the hours of divine service in another direction, to feed my master's horses."

Now it gives us real pleasure to record that since the first mooting of these questions, in October, 1853, the willing concurrence of the farmer in effecting a radical change in the hours hitherto observed on the Sabbath on East Kent farms has been more and more afforded. At the agricultural meeting of 1854 this matter, which had been discussed at their previous anniversaries, was again brought forward with an earnest spirit. In October, 1855, a meeting of county gentlemen and farmers took up the question again; and in September of the year following (1856) a still more influential meeting was held at Canterbury, William Deedes, Esq., M.P., taking the chair.

The resolution following was then proposed—

"That this meeting, being desirous of removing every obstacle to the religious and moral improvement of the farm labourers, recommends the adoption, henceforward, of such hours of stable attendance on the Sabbath as shall give every opportunity to farm servants to attend a place of divine worship."

This was followed by 255 signatures, including the names of the leading gentlemen, yeomen, and farmers of the eastern division of the county.

So the movement advanced. It was only necessary to show that time had insidiously engrafted upon Kentish farms customs and moral disabilities at once unnecessary and injurious to the labourer, and right-minded men lost no time in endeavouring to remove the evil.

Yet long custom is not broken through in a day, or even in years. Accordingly the year 1857, the fifth year of the movement, found something still to be done. There were farmers who still held back from an alteration in their hours on a Sunday, in compliance with the prejudices of many of the "servants," who clung to the old system, which gave them a pretext to neglect those holy services of God's house, which a low state of education too often unfitted them to enjoy. When reluctance "to change the customs" manifested itself among the men, it required some moral determination to carry out desirable changes, and to meet it might be some inconvenience, the labour market being barely supplied. Nor was this moral difficulty lessened; if A carried out the system, and not being backed by his neighbour B, had warning given him by his men, who were immediately taken *without a character*.

One remedy alone remained for this—association. If the farmers would agree to act on one and the same plan, and each of them to vindicate the honour of the Sabbath, no difficulty would remain. One more meeting, then, was convened on the 3rd of October last. Mr. Deedes again took the chair. The object of the meeting had the cordial support of Lord Winchelsea, Lord Sondes, Lord Cowper, and other influential persons. The association was proposed and carried, under the name of "The East Kent Agricultural Labourers' Association," and donations were received.

Little more remains to be added, in giving a summary of this movement, than to state that the first meeting of the committee has since been held, and the following advertisement circulated through the county papers:—

"East Kent Agricultural Labourers' Association.

"The committee of the above association, having held their first meeting on Monday, Nov. 16, feel it due to its supporters, and those interested in its operations, to lay before them the following statements:—

"1. That the object of the Society is the religious, moral, and social improvement of the agricultural labourers of East Kent, especially the farm-servants.

"2. That the committee have received information of a very encouraging character respecting the closing of farm-stables during the hours of divine service; of the increased domestic comforts now afforded to farm-servants; and of the success attending the establishment of night schools in various quarters.

"3. That, in their opinion, the first and most efficacious means of carrying out their object, above-mentioned, is the *closing of farm-stables during the hours of divine service;* and next to this, *the encouragement of night-schools.*"

The advertisement is then followed by an appeal to the public for support.

And now we have only to congratulate the agriculturists of East Kent and their farm-servants upon the successful commencement of such an improvement upon old customs, as that henceforward farm-service, in the particular above alluded to, shall be no hindrance between a man and his God. We congratulate the labouring class especially that night-schools hold out, in various quarters, the promise to every man who will help himself that he shall not be at a loss to find those who in turn will help him in his search after self-elevation and improvement. Why should it be said, in our day of progress and philanthropy, that any adult of the labouring class is unable to receive the blessings of divine and human knowledge because he is unable to read?

It gives us still more pleasure to learn that inquiries have reached the promoters of this movement from Oxfordshire, Hertfordshire, and Northamptonshire, with a view of themselves advancing, by some kindred movement, the well-being of the agricultural labourer in those counties.

We only trust that many other counties will be found to follow Kent and Norfolk; and that a reciprocal interest of classes, in the welfare the one of the other, will more than keep pace with the scientific and professional advances of the day. In that class of single farm-servants whose special improvement has been agitated in Kent, be it remembered, we see the expanding of that bulwark of our rural villages—the orderly, staid, trustworthy, respectful, and highly respectable "labourer"—the occupier of the neatest cottage—the father of the best-conducted family—the most faithful of servants to his earthly master, because also to his God—the most unvarying attendant at the house of God—one of the corner-stones of an English village.

A Kentish Plough.

"ENGLISH TRAITS," by R. W. Emerson.—Bacon said, "Rome was a state not subject to paradoxes"; but England subsists by antagonisms and contradictions. The foundations of its greatness are the rolling waves; and, from first to last, it is a museum of anomalies. This foggy and rainy country furnishes the world with astronomical observations. Its short rivers do not afford water-power, but the land shakes under the thunder of the mills. There is no gold mine of any importance, but there is more gold in England than in all other countries. It is too far north for the culture of the vine, but the wines of all countries are in its docks. The French Comte de Lauraguais said, "no fruit ripens in England but a baked apple"; but oranges and pine-apples are as cheap in London as in the Mediterranean. The *Mark-lane Express*, or the Custom House Returns, bear out to the letter the vaunt of Pope—

> "Let India boast her palms, nor envy we
> The weeping amber nor the spicy tree,
> While by our oaks those precious loads are borne
> And realms commanded which those trees adorn."

The native cattle are extinct, but the island is full of artificial breeds. The agriculturist, Bakewell, created sheep, and cows, and horses to order, and breeds in which everything was omitted but what is economical. The cow is sacrificed to her bag, the ox to his sirloin. Stall-feeding makes sperm-mills of the cattle, and converts the stable to a chemical factory. The rivers, lakes, and ponds, too much fished, or obstructed by factories, are artificially filled with the eggs of salmon, turbot, and herring. Chat Moss and the fens of Lincolnshire and Cambridgeshire are unhealthy, and too barren to pay rent. By cylindrical tiles and gutta-percha tubes five millions of acres of bad land have been drained, and put on equality with the

best, for rape-culture and grass. The climate, too, which was already believed to have become milder and drier by the enormous consumption of coal, is so far reached by this new action that fogs and storms are said to disappear. In due course, all England will be drained, and rise a second time out of the waters. The latest step was to call in the aid of steam to agriculture. Steam is almost an Englishman. I do not know but they will send him to Parliament next to make laws. He weaves, forges, saws, pounds, fans, and now he must pump, grind, dig, and plough for the farmer. The markets created by the manufacturing population have erected agriculture into a great thriving and spending industry.

LEICESTERSHIRE AGRICULTURAL SOCIETY.

The annual show of this society took place on Friday, Dec. 4, in the yard of the Bell Hotel, the spirited proprietor of which had greatly enlarged the space appropriated for that purpose, by erecting long ranges of comfortable sheds. The result was that though the quantity of stock was unusually large, there was an absence of all crowding, and the animals of all kinds were inspected with the greatest facility and advantage. Of the quality of the stock shown opinions varied, some thinking it one of the best shows in this respect the society has had, and others considering that there were many rough things sent, which never ought to have appeared in an exhibition. The decisions of the judges of stock too did not meet with universal approval, as they were considered to have leaned too much to bulk, to the neglect of symmetry and quality, and to have passed over unnoticed some of the very best animals shown, amongst others the excellent sheep of Mr. Bradshaw, of Burley. Mr. Wortley of Ridlington showed some very excellent beasts, and was fortunate enough to secure three prizes. Mr. Spencer's sheep were also very good, Almost the only vegetables and roots shown were sent by Mr. W. Carver, of Ingarsby.

LIST OF THE PRIZES.

BEASTS.

For the best ox under five years old, of any breed, open to all counties, £15, Mr. Edward Wortley, of Ridlington. Second prize, £5, Mr. Robert Lynn, of Stroxton, near Grantham.

For the best ox under four years old, of any breed, bred and fed in the county, a silver cup, value £10, Lord Berners, of Keythorpe-hall. Second prize, £5, Mr. Abraham Perkins, of Arnesby.

For the best short-horned ox, fed by a member of the society, £5, Mr. Thomas Wilson, of Knaptoft-hall.

For the best Scotch or Welch ox, fed by a member of the society, £5, Mr. J. E. Bennett, of Husbands Bosworth Grange.

For the best Hereford, Devon, or Shropshire ox, fed by a member of the society £5, Mr. Abraham Perkins, of Arnesby.

For the best fat cow or heifer, of any breed, age, or weight, open to all counties, £10, Mr. Edward Wortley, of Ridlington. For the next best ditto, £5, Mr. William Winterton, of Wolvey Villa.

For the best fat heifer, under four years old, fed in the county, a silver cup, value £5, Mr. Samuel Spencer, of Snarestone.

For the best dairy cow, fed in the county, that has produced a calf, is either in milk, or has been regularly milked twice a day to the 10th of October, £10, Earl Howe, of Gopsall-hall. For the next best ditto, £5, Mr. George Townshend, of Stoney Stanton.

For the best pair of in-calf heifers, under three years old, open to all counties, £5, Mr. Richard Timms, of Braunstone. For the next best ditto, £3, Mr. C. J. Bradshaw, of Burley-on-the-Hill.

For the best pair of heifers, under two years old, open to all counties, £5, Mr. Thomas Ivens, of Lutterworth. For the next best ditto, £3, C. W. Packe, Esq., M.P., of Prestwold-hall.

For the best bull, above ten months, and under two years old, breeding open to all counties, £10, Earl Howe, of Gopsall-hall. For the next best ditto, £5, Mr. Joseph Sharp Spencer, of Higham-on-the-Hill.

For the best bull, of any breed or age, that has served cows in the previous season, £5, Earl Howe, of Gopsall-hall. For the next best ditto, £2, C. W. Packe, Esq., M.P.

SHEEP.

For the best pen (of three) under twenty-two months old, of long-woolled fat wether sheep, open to all counties, £7, Mr. Edward Wortley, of Ridlington. For the next best ditto, £3, Mr. T. H. Simpkin, of Hoby.

By the Right Hon. the Earl Howe. For the best pen (of three) under twenty-two months old, of long-woolled fat wether sheep, bred and fed in the county, £5, Mr. B. Simpkin, of Hoby. For the next best ditto, £3, Mr. William Everard, of Narborough Wood.

For the best pen (of three) under twenty-two months old, of short-woolled or cross-bred fat wether sheep, open to all counties, £5, Mr. Samuel C. Pilgrim, of Burbage.

By the Treasurer. For the best four long-woolled ewes, which have suckled lambs to the 1st of July, 1857, open to all counties, £5, Mr. Joseph Sharp Spencer, of Higham-on-the-Hill. For the next best ditto, £3, Mr. B. Simpkin, of Hoby.

For the best longwoolled theaves, that have been put to the ram, and supposed to be in-lamb, open to all counties, £5, Mr. John Palethorpe, of Harlaxton. For the next best ditto £3, Mr. William Everard, of Narborough Wood.

For the best four short-woolled ewes, which have suckled lambs to the 1st of July, 1857, open to all counties, £4, Mr. Samuel C. Pilgrim, of Burbage.

For the best four pure short-woolled theaves, that have been put to the ram, and supposed to be in-lamb, open to all counties, £3, Mr. Samuel C. Pilgrim, of Burbage.

For the best pen (of five) long-woolled ewe lambs, open to all counties, £3, Mr. William Everard, of Narborough Wood.

PIGS.

In-pigged or suckling sow, or gelt, breeding open to all counties, £5, Mr. W. H. Harrison, Clipstone House.

Boar, breeding open to all counties, £4, Mr. James Marriott, Floore.

Fat pig, under 12 months old, open to all counties, £2, Mr. G. Beale, jun., Frolesworth; 2nd, £1, to ditto.

By Lord Berners.—Fat pig, under 18 months old, open to all counties, £2, Mr. G. Beale, jun., Frolesworth; 2nd, £1, Mr. Wm. Benskin, Rearsby.

HORSES.

By Lord Berners.—Gelding or filly (two years old) *bona fide* the property of a person occupying at least 50 acres as tenant, best adapted to the general purposes of agriculture in the county, £5, Mr. J. E. Bennett, Husbands Bosworth Grange.

By Lord Berners.—Gelding or filly (one year old) as in Class 30, £5, Mr. J. E. Bennett.

In-foal mare, the property of a tenant farmer, best adapted for the general purposes of agriculture, £5, Mr. H. B. Wayte, Peatling.

By Lord Berners.—Foal best adapted for agriculture, the property of a tenant farmer, £3, Mr. John Campion, Sharnford.

By Mr. Thomas Gilbert.—Cart foal by Leicestershire Hero, Young England's Glory, or Derby, £3, Mr. John Campion, Sharnford.

EXTRA STOCK.

Breeding beast shown as extra stock, £5, C. W. Packe, Esq., M.P.

By C. W. Packe, Esq., M.P.—Fat beast shown as extra stock, a silver cup, value £5 5s., Lord Howe.

By C. W. Packe, Esq., M.P.—Pen of three Leicester or long-woolled sheep, shown as extra stock, a silver cup, value £5, Mr. Breedon Everard, Groby.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

A MONTHLY COUNCIL was held on Wednesday, the 2nd of December: present, the Right Hon. LORD PORTMAN, Trustee, in the Chair, Lord Walsingham, Lord Southampton, Lord Feversham, Right Hon. the Speaker, Sir Watkin Williams Wynn, Bart., M.P., Sir John V. B. Johnstone, Bart., M P., Mr. Dyke Acland, Mr. Raymond Barker, Mr. Barnett, Mr. Barthropp, Mr. Brandreth, Mr. Caldwell, Mr. Cavendish, Colonel Challoner, Mr. Brandreth Gibbs, Mr. Fisher Hobbs, Mr. Wren Hoskyns, Mr. James Howard, Mr. Jonas, Mr. Lawes, Mr. Milwood, Mr. Slaney, M.P., Mr. Banks Stanhope, M.P., Mr. Thompson, Mr. Torr, and Mr. Burch Western.

The following new Members were elected :—

Best, the Hon. and Rev. Samuel, Abbott's Ann, Andover
Bowen, Pryse, Shrawardine Castle, Shrewsbury
Brown, Edward, Oaklands, St. Alban's
Butler, John Field, Childerditch Hall, Brentwood
Fry, Thomas, Baglake Farm, Longbredy, Dorsetshire
Gardner, Captain Thomas, Sea View, Ryde, Isle of Wight
Gibbs, Thomas, Down-street, Piccadilly, London
Graham, Thomas, jun., Abingdon, Berkshire
Hardacre, Richard, Hellifield, Leeds
Knox, Octavius Newry, South-Collingham, Newark, Nottinghamshire.
Locock, Edmund, South Elkington, Louth
Madgwick, William, jun., Alciston, Lewes
Minton, Alfred, Clewer Court, Windsor
Moorsom, C. R., Cotham, Redcar, Yorkshire
Ostler, John Lely, Grantham, Lincolnshire.
Purton, William, The Woodhouse, Cleobury-Mortimer
Sadler, Benjamin Greame, Linen Hall, Belfast
Simpson, Pinder, Hendon, Middlesex
Smith, Henry, Brierley Hill, Dudley
Turner, Edward Rush, St. Peter's Iron Works, Ipswich
Turner, Frederick, St. Peter's Iron Works, Ipswich
Veitch, James, jun., Exotic Nursery, Chelsea
Warner, Henry, jun., Hawkley, Petersfield
Woodford, William, Bidford Grange, Alcester
Yonge, Rev. William, Rochbourne, Fordingbridge.

FINANCES.—Mr. Raymond Barker, Chairman of the Finance Committee, presented to the Council the monthly report on the accounts of the society, from which it appeared that the current cash balance in the hand of the bankers at the end of the previous month was £153.

EXPENCES.—Lord Portman, as Chairman of the Expenses Committee, made a further report on the progress of the committee in their consideration of the various topics referred to them. He informed the Council, that the excess of payments over receipts on account of the Salisbury Meeting had been considerably reduced by the adoption, to a certain extent, of the recommendations of the committee, and he trusted that a much further reduction would be effected, not only by a steady adherence to economical arrangement on the one hand, but to an increase in the receipts on the other. His lordship concluded his communication by reading to the Council the several details, under each head of recommendation, which the report contained.

PRIZE ESSAY.—Mr. Thompson, Chairman of the Journal Committee, reported the following adjudication in the class of Essays and Reports :

To the Rev. William Beevor, of Cowbridge, Glamorganshire, the prize of £20, for the best essay on the comparative advantages of entering upon farms in spring and autumn, with instructions to the young farmer on his entering at either season.

AGRICULTURAL CHEMISTRY.—Mr. Wren Hoskyns, Chairman of the Chemical Committee, read to the Council a letter addressed to him by Professor Way, the consulting chemist of the Society, dated Milan, the 20th of November last, and tendering his resignation of that office, which the Council accepted, and passed a vote of thanks to Professor Way for his past services to the Society in that capacity. A special committee was then appointed, consisting of the members of the chemical and finance committees, with the addition of Lord Feversham, Mr. Slaney, M.P., and Mr. Fisher Hobbs, to consider of an improved arrangement for the chemical business of the Society.

AGRICULTURAL IMPLEMENTS AND MACHINERY.—Colonel Challoner, Chairman of the Implement Committee, read the following :

REPORT.

The Implement Committee have, agreeably with the instructions of the council, afforded an opportunity to the exhibitors and judges of implements and machinery at the Society's country meetings, during the last three years, of offering any suggestions relative to the construction and trial of steam-engines and other agricultural machinery at the Chester Meeting, and the committee received fourteen communications on the subject.

The committee having taken these suggestions, and the report made upon them by the Society's consulting engineer, into their consideration, beg to make the following recommendations to the Council:—

1. That in steam-boilers the tubes should not be placed nearer to each other than one inch.
2. That the evaporative power of the boiler may, if thought necessary, be ascertained.

   Remark by Mr. Amos.—"This course appears to me to be good only indirectly: for if the combination work well as a whole, and in its marketable form, the Society need hardly look too minutely into details, unless they see fit to do so."
3. That the parts of the steam-engines should admit of being taken to pieces, and their parts, as well as those of other machines, be examined as to mechanical detail.
4. That the coal used in the getting-up of steam be selected and weighed, as usual, under the direction of the judges; and although the Llangennych variety has been hitherto used as a constant standard for marking progressive improvement in the steam-engine, on account of its uniformity of character and absence of smoke in combustion, that the common bituminous coal of the country may be employed in its place, should the judges think proper to adopt it.
5. That the trials of steam-machinery might, in future, be conducted under sheds, should the advantages proposed to be gained by their adoption be considered equivalent to the expense incurred in their erection.
6. That well-tested self-acting breaks be employed in the trials of steam-engines.
7. That the judges be at liberty to employ, as heretofore, any scheme of data or points that may, in their opinion, best lead them to a clear decision on the practical value of any engine or machine.
8. That higher prizes might be given for steam-engines, on condition that the prize-engine in each class shall be lodged in some public exhibition during the period while it holds the prize; and that the maker will supply, in each case, an equal machine at the price stated in his original certificate of entry.

Some of the suggestions offered by the implement makers to the committee have been found to be either discordant among themselves, or to refer to conditions adopted by the Society at the Carlisle and other meetings; others are connected either with details of practical management in the stewards' and judges' departments, or with questions on which the committee are not at present prepared to offer any recommendations to the Council;—but wherever the committee have found it advisable, they have introduced into the conditions and regulations of the proposed prize-sheet for next year modifications in accordance with the suggestions made to them.

PRIZES FOR IMPLEMENTS—1858.

The committee beg to recommend the following prizes for implements at the Chester Meeting:—

	£
Portable steam-engine, above 8 and not exceeding 12-horse power	25
Portable steam-engine, not exceeding 8-horse power	25
Second-best ditto	10
Fixed engine, not exceeding 10-horse power	20
Second-best ditto	10
Boiler for a fixed engine, not exceeding 10-horse power	10
Portable thrashing-machine, not exceeding 6-horse power	10
Portable thrashing-machine, not exceeding 8-horse power, for large occupations	15
Portable thrashing-machine, not exceeding 8-horse power, that will best prepare the corn for the finishing dressing machine	15
Portable combined thrashing-machine, that will best prepare the corn for market, not exceeding 8-horse power	15
Fixed combined steam thrashing-machine, for preparing corn for market, not exceeding 10-horse power	20
Fixed combined steam thrashing-machine, for preparing corn for market, not exceeding 8-horse power	10
Corn-dressing machine	5
Corn-dressing machine, for preparing corn for market after being riddled and screened	5
Screen for corn	3
Screen for seed	3
Chaff-cutter, for horse or steam-power	5
Second-best ditto	3
Chaff-cutter, for hand-power	3
Second-best ditto	2
Grinding-mill, with steel or stone grinders, for grinding agricultural produce into meal, to be worked by horse or steam-power	10
Grinding-mill, with steel grinders, for grinding agricultural produce	5
Linseed or corn-crusher	5
Oilcake-breaker	5
Oilcake for common cake	3
Bone-mill, to be worked by steam or other power	10
Bone-dust mill	5
Turnip-cutter	3
Turnip-cutter, for hand-power	3
Root-pulper	3
Churn	3
Cheese-making apparatus	3
Cheese-press	3

Miscellaneous awards for essential improvements in any of the implements or machinery exhibited—21 silver medals.

Any new implement, such sum as the Council, on the report of the judges, may think proper to award.

Should the Council decide again to offer the prize for the best steam-cultivator, the committee recommend that it be offered in precisely the same terms as last year.

(Signed) C. B. Challoner, Chairman.

CONDITIONS OF THE PORTABLE STEAM ENGINE.

1. One of the portable steam engines must not be more than eight horses nominal power, nor must the diameter of the cylinder be more than 9¾ inches. The one above eight must not exceed twelve horses nominal power, must have two cylinders, and the diameter of each cylinder must not exceed 8 inches.

2. The tubes in the boiler must not be less than 2½ inches diameter, not less than No. 12 on the metal gauge in thickness, nor placed a less distance apart than one inch from each other. The tube plates must be made of either "Lowmoor" or "Bowling" iron, and the "trade mark" of the iron company must be legible on each plate.

3. The exhibitor will be required to furnish to the Society, along with the specification, a longitudinal and transverse sectional plan of the boiler, showing the action of the fire upon the flues, and also to state in writing:—

(*a*) The thickness and quality of the boiler plates.
(*b*) The diameter of the cylinder.
(*c*) The length of the stroke of the piston.
(*d*) The number of revolutions, and diameter of the crank and shaft, which must be made of wrought iron.
(*e*) The diameter and weight of the fly-wheel.
(*f*) The diameter of the driving pulley (which must not be less than 6 inches wide, nor move at a less velocity than 1,600 feet per minute). A second pulley must also be fitted, and which must not be less than 5 inches wide, nor move at a less velocity than 900 feet per minute, for driving chaff-cutting or other machines requiring a slower motion than can be given by the large driving pulley.
(*g*) The number of horse-power the engine is calculated to work at.

4. The engine must be provided with a good water-gauge, and with a short piece of pipe fitted with a cock, having a thread to fit the ½-inch gas pipe, for the purpose of fixing a pressure gauge.

5. If the engine be worked on the expansive principle, it is desirable that the means used for cutting off the steam be of a simple character. No force-pump must be fitted with more than two valves, and these must be easy of access. If a heater for water be used, it must be so constructed that the engine will work either with or without it.

6. The Society will be empowered to select any of the engines exhibited, for the purpose of driving other machinery under trial, and will pay the exhibitor £1 per day for the use of the engine and a competent attendant during the time the services of such engine may be required.

7. In adjudicating on the merits of the engine, reference will be had to the simplicity of construction and the probable durability of the engine, considered as a whole and in detail, also the portability of the engine, without losing sight of the strength required for safety, the economy of working, and the price.

8. The Judges will be instructed to have the boilers filled properly with water, the steam got up to the working pressure of 45 lbs. on the square inch, the engine set to work for a short time, and then cooled down.

9. The exhibitor will then be required to take the engine to pieces in the presence of the Judges, and withdraw the piston, slide, expansion valve, and pump valves, for examination. Two men will only be allowed to assist in the operation, and the time of taking to pieces and replacing the parts will be noted. When the whole is put together the engine will undergo the trial of working in the ordinary manner, and in accordance with the practice of former meetings. If after trial the Judges should require any one or more of the tubes withdrawn for examination, the exhibitor shall withdraw such tube or tubes.

CONDITIONS OF FIXED STEAM ENGINES.

1. The fixed steam engine must not be more than ten horses nominal power, and the diameter of the cylinder must not exceed 11½ inches.

2. The exhibitor will not be required to bring a boiler, as steam will be furnished by boilers supplied by the Society, but he will be required to fix the engine, also to find the materials for doing so, at his own expense, and in such a position in the Trial Yard as may be pointed out to him.

3. He must also furnish the Society with plans and specifications, fully describing the boiler and fittings that he would supply to his customer with the engine he exhibits, such boiler to possess the capacity of 25 superficial feet of effective heating surface and ¾ of one foot of effective fire-grate for each horse-power of the nominal power of the engine. No

tubes will be allowed of less diameter than 2½ inches, nor thinner than No. 12 on the metal gauge. Also the leading particulars of the engine he intends to exhibit; such as—

(*a*) The horse-power of the engine.
(*b*) The diameter of the cylinder.
(*c*) The length of stroke.
(*d*) The number of strokes per minute.
(*e*) The diameter of crank-shaft.
(*f*) The diameter and weight of fly-wheel.
(*g*) The diameter of driving pulley (which should not be less than 7 inches wide, nor travel less than 1,200 feet per minute).

The greatest attention will be paid by the Mechanical Judges to the drawings and specifications relating to the boilers of the Prize Fixed Engines. Such drawings and specifications will remain the copyright property of the Society; and will be published in the Journal of the Society for the purpose of guiding its members in making their purchases.

4. The engine exhibited must be supplied with a governor, and have a starting-cock to regulate the supply of steam, and be fitted with a thread equal to the 2-inch gas pipe.

5. If the engine is worked on the expansive principle, a simple means must be used for cutting off the steam. No force-pump must be fitted with more than two valves, and these must be easy of access. If a heater for water be used, it must be so constructed that the engine will work either with or without it.

7. In adjudicating on the merits of the fixed engines, reference will be had to the price, simplicity of construction, probable durability of the whole and in detail, and the means provided for easy access to the working parts, and to economy of fuel.

CONDITIONS OF FIXED STEAM BOILERS.—"SPECIAL PRIZE."

The boiler must possess an effective heating surface of 25 superficial feet and three-fourths of one foot superficial of effective fire-grate surface for each nominal horse-power. Clear and concise drawings and specifications, with the cost of forming the boiler-setting, with its flues and passages up to the entrance into a chimney, must be furnished to the Society, for publication, should the Council think fit to publish them.

If tubes are used, none less than 3 inches diameter and 1 inch apart will be allowed; and no tube-plates shall be used which are not made either of "Low Moor" or Bowling iron, and bearing the ironmaster's trading mark. The fittings which the exhibitor supplies must be shown with the boiler, and a guarantee given that he will supply the public with boilers and fittings of a similar description, at the price named, for twelve months certain after the prize has been awarded to the exhibitor.

CONDITIONS OF CHAFF-CUTTERS AND MILLS.

Chaff-cutters will be required to cut chaff three-eighths of one inch in length, in the trial. The exhibitor may provide means for cutting various lengths, to show the usefulness of his production. The Judges will be instructed to use thin slips of wood for determining the length of chaff cut; and if the deviation from the given length of three-eighths of an inch is, in their judgment, too much departed from, they may refrain from taking any notice of the machine in question; and in estimating the *weight* of chaff cut, allowance must be made and taken according to the length of chaff cut.

Grinding mills will be fairly set to work, and their production compared with a sample which the Judges shall cause to be produced by one mill, and which produce shall, in their estimation, be adapted for the farmers' purposes of feeding. The mill under trial shall be "set" until it produces like meal; and the *time*, *power*, and *quantity of work* noted.

Steel mills for grinding will not be expected to produce softened meal, although any mill or combination, with rollers or otherwise, which will do so, will receive consideration from the Judges; but mills of this class generally will be tried and compared in the class as grinding mills with stones are compared in their class.

SPEED AND PRESSURE.

All implements turned by the winch or hand-crank shall not be worked, at any trial, beyond the following speed—namely, 42 revolutions per minute for 12-inch crank, 37 revolutions for 14-inch crank, 32 revolutions for 16-inch crank; and, in addition to the winch-handle which must be supplied with the machine, for the purpose of trial, a pulley not less than 4 inches wide, of the same radius as the winch, must be fitted to each machine. The machine, in its trial, will be driven by the pulley of the testing machine, which pulley is 31 inches diameter, and will make 32½ revolutions per minute.

Chaff-cutting and other small machines, worked usually by horses and by steam power, will be worked, when under trial, by pulleys not less than 5½ inches wide, moving with a velocity of, or about, 900 feet per minute.

Exhibitors are requested to pay particular attention to the instructions given for the speed and working of their machines, as the Judges may refuse to try any machine not fitted in accordance with the instructions.

The working pressure of steam to be 45lbs. per square inch, which must not be exceeded.

The Council adopted this report, and ordered that its recommendations should be introduced into the implement prize sheet for the Chester Meeting, now in the press, and awaiting publication.

AGE OF BULLS.—On the motion of Mr. Torr, seconded by Mr. Milward, it was decided that the age at which the old Bulls might compete should be raised from four to six years.

POULTRY SHOW.—Mr. Milward gave notice, that at the Monthly Council, in February next, he should move that after 1858 there shall be no exhibition of Poultry at the country meetings of the Society.

ENTRY FEES AND SHEDDING.—The Expenses Committee having called the attention of the Council to the contribution which, in their opinion, the exhibitors of stock (as in the case of those of implements) should make toward the great expenses incurred for the accommodation of their animals during the show, it was resolved that exhibitors of stock should contribute to the expenses of the yard. It was then, on the motion of Mr. Torr, resolved, "That the charge for all stock exhibited shall be 5s. for each entry, in addition to the 10s. paid by non-members." This resolution was ordered to be added to the prize sheet.

SHOWYARD.—Lord Portman, as Chairman of the General Chester Committee, read to the Council the report of that committee, in which it was strongly recommended that the arrangements for the showyard at Chester should be finally settled by February next; and with a view to enable the council to decide on the arrangement to be adopted, the committee would be prepared by that time to lay before them the plan which the committee would recommend for adoption.

DINNER.—On the motion of Sir Watkin Wynn, Bart., M.P., seconded by Mr. Fisher Hobbs, the Council postponed until their monthly meeting in February the further consideration of the question whether any dinner should be ordered under the responsibility of the society. Mr. Banks Stanhope, M.P., gave notice of the following motion he should bring forward on that occasion:—"That no dinner of the Royal Agricultural Society of England shall for the future take place at the annual country meeting, unless the locality shall guarantee a sufficient number of tickets to defray the expense."

IMPLEMENT JUDGES.—The Council decided that it shall be the duty of the Implement Committee, in each year, to report to the Council the number of judges required for the implement department, previously to the meeting of the committee for the selection of judges. The Council resolved not to adopt the recommendation of the Expenses' Committee on the question of the number of the judges of stock.

ORDERS OF COUNCIL.—On the motion of Lord Portman, seconded by Mr. Raymond Barker, the following motion was agreed to: "That it be a bye-law of the society, that no order in council shall be altered without one clear month's previous notice being given to each member of the council."

CODE OF BYE-LAWS.—On the motion of Mr. Fisher Hobbs, seconded by Mr. Brandreth Gibbs, the Council ordered that the bye-laws and resolutions of council, which are now in force, be collected together, complete up to the end of the present year, and printed for the use of the members of council.

VICE-PRESIDENT.—On the motion of Mr. Raymond Barker, seconded by Lord Feversham, Viscount Eversley was unanimously elected a vice-president of the society, in the place of the late Earl Fitzwilliam.

RESPONSIBILITY OF IMPLEMENTS AND STOCK.—On the motion of Mr. Brandreth Gibbs, seconded by Mr. Fisher Hobbs, the following resolutions were agreed to:—

That in future the delivery orders which are now in use for both live stock, implements, &c., be discontinued.

That a clause be inserted in the conditions stating that the society will not in any case hold itself responsible for any loss, damage, or mis-delivery of such live stock or implements, or other articles exhibited at the society's shows.

METROPOLITAN MEETING.—On the motion of Mr. Brandreth Gisbb, seconded by Mr. Fisher Hobbs, a committee was appointed — consisting of Lord Portman, Lord Walsingham, Lord Feversham, the Speaker, Mr. Barnett, Mr. Brandreth, Colonel Challoner, Mr. Brandreth Gibbs, Mr. Fisher Hobbs, Mr. Wren Hoskyns, Sir John V. B. Johnstone, Bart., M.P., Mr. Jonas, Mr. Milward, Mr. Thompson, and Mr. Torr—to consider the following subject, and to report their recommendations to the Council, viz., as to how far it will be expedient for the Society to make application to the Royal Commissioners for permission to hold a show, in an early year, on the admirable site which the land lying between the Kensington and Brompton roads, and adjacent to that portion of Hyde Park on which the Great Exhibition of 1851 was held, now offers for the purposes of the Society, if such permission can be obtained.

LECTURES AND MUSEUM.—Mr. Henry Cole communicated to the Council, on the part of the Committee of Council on Education, an offer to the Society, under certain conditions, of the use of the museum and lecture room of the South Kensington Museum. The Council received this communication with an acknowledgment of their thanks.

RAILWAYS.—Mr. Fisher Hobbs called the attention of the Council to the great advantage of obtaining, if possible, earlier decisions from the railway companies of the facilities they are willing to grant to the Society's Exhibitors at the Country Meetings, and the Secretary was directed to enter into communication with the different companies on that point.

STEAM-SPADE.—Major-General Grey transmitted to the Council, by direction of H.R.H. the Prince Consort, a communication addressed to His Royal Highness on the subject of a steam-spade recently invented in the United States. The Council ordered an acknowledgment of their thanks for the favour of this communication, which they referred to the Implement Committee.

The HALF-YEARLY MEETING of members was held on Friday last, at the Society's House, Hanover Square. The chair was taken at 11 o'clock by the President of the year, Lord Berners. Among those present were Lord Feversham, Col. Challoner, Mr. Barrow, M.P., Lieut.-Col. Townley, Mr. R. Barker, Mr. Bramston, M.P., Mr. Slaney, M.P., Mr. Badham, Mr. W. F. Hobbs, Mr. Barthropp, Mr. B. Webster, Mr. H. Wilson, Mr. Sainsbury, Professor Simonds, Professor Way, Mr. H. Corbet, Mr. Jonas Webb, the Rev. James Linton, Mons. Trehonnais, Mr. J. C. Nesbit, Mr. Jonathan Gray, Mr. Moore (Wilts), Mr. S. Sydney, &c., &c.

The Secretary, Mr. Hudson, read the following report of the Council:—

REPORT.

The Society has gained since the last half-yearly meeting 150 new members on its list, and consists, at the present time, of—

83	Life Governors,
135	Annual Governors,
908	Life Members,
4074	Annual Members, and
18	Honorary Members.
5218	

The Council have unanimously elected Viscount Eversley one of the Vice-Presidents of the Society, in the place of the late Earl Fitzwilliam.

The funded capital of the Society stands at £9,264 8s. 11d. in the New Three-per-cents. Stock.

Professor Way, the Consulting-Chemist of the Society, having tendered his resignation of that office, which the Council have accepted, a special Committee has been appointed to report to the Council, in February next, their recommendations of arrangements to be adopted for the discharge of the duties of that appointment.

Professor Simonds, the Veterinary-Inspector of the Society, has made his report to the Council of his observations and investigations abroad, on the occurrence and nature of the Cattle-plague on the confines of Poland, Prussia, and Austria; and the Council have transmitted to the Highland and Agricultural Society of Scotland, and to the Royal Agricultural Improvement Society of Ireland, a counterpart of that report, Professor Simonds has also made several verbal reports to the Council on his investigations into the nature of diseases which have broken out in several parts of the country among the cattle and sheep of members of the Society. He has also expressed to the Council his decided conviction of the contagious character of that fatal and prevalent malady pleuro-pneumonia.

The Salisbury Meeting has been one of the most remarkable assemblages of live-stock and implements ever held in this country. Almost uniform excellence distinguished the several classes of the animals exhibited, while the implements were marked by a high degree of simplicity combined with efficiency. The Show itself, too, was one of the largest ever held by the Society, and was attended by a greater number of visitors than on any former occasion. The success of that meeting affords to the Council a well-grounded assurance of the practical value of the Society's operations in carrying out the great national objects for which it was founded; and encourages them in their continued endeavours to render the future country meetings still more effective, if possible, in promoting agricultural improvement throughout the kingdom, without the risk of infringing to an injurious extent on the financial resources of the Society. In order to combine these objects the Council have under their consideration the adoption of several proposed plans which appear likely to lead to improved arrangements in the Country Meeting department. The Mayor and Corporation of Salisbury and the Local Committee co-operated most cordially with the Council in carrying out the details of the Meeting to so successful an issue; and the Members were indebted to the Right Hon. Sidney Herbert, M.P., for the reception he gave them at Wilton; to Mr. Rawlence and Mr. Squarey, for the inspection of their water meadows; and to Mr. Squarey for the interesting lecture he delivered on the occasion, in explanation of their construction and peculiar value; as well as to Mr. Stephen Mills for his invitation to inspect the light-land system of Wiltshire farming, as carried out on his own extensive farms in that county.

The Country Meeting to be held next year at Chester will be distinguished by the unusual amount of Local Prizes placed at the disposal of the Society by the Local Committee of that city, by the triennial exhibition and trial of steam engines and

agricultural steam machinery generally, and by the peculiar advantages of its position in reference to railway communication.

The local prizes may be represented by the following classification:—

Cheshire Cheese (made in the district)	£420
Dairy Maids and Cheese Makers	21
Dairy Cattle	170
Horses	215
Welsh Cattle	195
Established Breeds (not including Short-horns, Herefords, or Devons)	30
Sheep (Welsh, Shropshire-Downs, and Cheviots)	230
	£1231

The prizes of the Society for the Chester Meeting are included in the following schedules:—

I.—Live Stock.

Short-horned Cattle	£170
Herefords	170
Devons	170
Cattle of other Breeds	45
Agricultural Horses	130
Dray Horses	75
Other Horses	105
Leicester Sheep	90

Cheese Press	3
Steam-Cultivator	500
	£775

Miscellaneous awards.....21 Silver Medals.

The Prize Sheets, containing the special terms in which these various prizes are offered, the conditions under which the competition for them will take place, and the general regulations for exhibition and trial, are now in the press, and, when finally corrected, will be ready for distribution. The Implement Prize Sheet will include the recommendations of the Implement Committee, in reference to the suggestions obtained by a circular issued, by order of the Council, to each exhibitor in that department, and to each of the Implement Judges, during the last three years.

By Order of the Council,
James Hudson, Secretary.

London, December, 1857.

The Rev. J. Linton moved the adoption of the report.

Mr. Moore seconded the motion.

Mr. Sidney said it would be in the recollection of some of the gentlemen present, that the last occasion on which they had an opportunity of expressing an opinion upon the manner in which the Society's affairs were conducted, was at Salisbury, in the month of July. On that occasion he made some observations in reference to that subject, and all who knew him, he was sure, would believe that in any observations he might make he was actuated solely by the warmest wishes for the Society. Now, he felt that he was perfectly justified in calling the attention of the Council and members to this subject, because, although they had prepared a very flourishing report of the Society's proceedings, they could not help being aware, from the little information which oozed out from time to time, that the finances of the Society were not in so satisfactory a state as could be desired. That fact was proved by the circumstance that a committee, over which Lord Portman presided, had several times investigated the condition of the finances, and that in order to improve them it had been found necessary to recommend the reduction of expenses of a necessary and important character. For instance, just before the Salisbury Meeting, in the summer, the Finance Committee recommended that the services of a number of the judges should be dispensed with, and that the payments made to the yardmen should be discontinued.—[Colonel Challoner: It was not the Finance Committee who did that; it was the Expense Committee.]—But in this instance they considered it so closely, that it appeared a mistake was made; for, when the report of the committee came before other parties more experienced than themselves, the recommendation as to the judges was disregarded. The judges, whom it was proposed to dispense with, were re-appointed; and even then it was found that the gentlemen at Salisbury, who had that business in their hands—notwithstanding all their zeal and industry—were greatly over-worked. If, then, the Society was in such a condition that reduction of expenditure, recommended by a committee, could not be effected with advantage to the Society, it must be evident that something was wanted to be done. They were now in the 20th year of the history of the society. During that period it had doubtless effected great things, and it had held a magnificent exhibition every year; but what was the reason they had not an income sufficient to do largely and liberally all that was required? True, after a falling off in the number of members for a series of years, the tide had turned, and their ranks were beginning to increase. Still there was something that ought to be done which had not been done, for the number of members was much less than it was ten years ago, although agriculture was never in a more flourishing condition than at the present moment; and, instead of a few gentlemen here and there feeling an interest in experimental farming, there was scarcely a parish in England in which some tenant farmer or other had not been carrying out cultivation in a high and improved style (Hear, hear). Now, he believed that, inasmuch as there were 10,000 parishes in the kingdom, there was no reason whatever why, if the society were properly conducted, it should not have 10,000 members. But they had 5,000 members, from whom a large income was derived. Nevertheless, they had only one great event in the year, and that was their annual country show. On those occasions they certainly did bring the world together, and accomplished great things. But, in his opinion, it was not enough to do great things once a-year; and if they glanced at other scientific societies it would be seen that those institutions created many opportunities for bringing their associates together. True, the society had its Wednesday meetings; but all who were in the least acquainted with them knew that, as at present conducted, they were very little better than a farce; for this reason, that no announcement was made of the business to be transacted on those days—a course of proceeding which was condemned by the practice of the other societies of England. It had happened again and again that interesting discussions had taken place at these weekly meetings, and that those discussions were not reported in the journals which circulated among the tenant farmers, simply because it was the absurd and mistaken rule to exclude reporters; while the official report was so meagre, that little information was to be gleaned from it, and very often even that did not find its way into the hands of the public until months after. As an instance of this, let him remind them of what took place last year, when the whole agricultural world being alarmed by the progress of the fatal cattle disease on the Continent, the society commissioned Professor Simonds to go abroad and make a report upon the subject. The learned professor returned home, and read a most interesting paper to us; but it never appeared, though he heard now that it was about to be published. There was no doubt they might

command the best agricultural knowledge of the day, if they would only adopt the simple method of announcing what papers were to be read at their meetings, and allowing the gentlemen who represented the agricultural papers to attend and report the discussion. He believed, also, that the adoption of such a plan would create new interest in the society, and largely augment the number of its members. The next subject to which he would allude was the Journal; and he ventured to say that its management had greatly disappointed the subscribers. If they wished to see what an agricultural journal might be made, let them turn to the pages of the *Bath and West of England Agricultural Journal*," which was an admirable work, replete with the most valuable information. The fact was that the management of the *Journal* of the Royal Agricultural Society was entrusted to three gentlemen, and he had never yet known the office of editor conducted as it ought to be when put in commission like the Chancellor's seal. With regard to the prizes which were to be offered at their next country meeting. Cheshire, they well knew, was a dairy county; and it was a curious fact that, although the Society had been nearly twenty years in existence, and had held 17 or 18 country meetings, they had never yet had a trial of churns on a large scale. Three quarts of cream was the utmost they had ever tried; and he had been informed, by persons who kept dairies, that the trial of churns should be conducted on a larger scale in order to be of practical use. He observed that prizes were to be offered at Chester for chaff-cutters, and root-slicers, and other things equally familiar, and for which prizes had been given ever since the Society was established. Now, these implements were just the same now as they were 17 years ago; and he would throw it out for the consideration of the Council whether they had not better strike some of these standard implements off the list, and reserve their prizes for machines in which a good deal was yet to be done before they attained perfection. It would not have been necessary for him to make these observations if they had not followed the practice described at the Salisbury Meeting, when it was said that their Council were elected for life, and elected their successors (No, no). He did not mean to say it was in the charter, but it was, no doubt, practically the case. In conclusion, he said he believed that if they had a larger infusion of gentlemen from the different counties in the Council, instead of continuing on the list a number of gentlemen who could not attend, it would popularise the Society and render it as flourishing as it ought to be.

The CHAIRMAN said it was highly desirable that reports like Professor Simonds' should appear sooner. The sooner they were published the better. He was under the impression that notice of the Wednesday meetings was always given a month beforehand.

The Secretary said the Wednesday meetings were entirely dependent on casual communications. Whenever any communication of importance had been received, notice had been given of it.

The motion for adopting the report was then put, and agreed to.

Mr. RAYMOND BARKER then read the balance-sheet of receipts and expenditure for the half-year ending the 30th of June last.

Half-yearly Account from the 1st of January to the 30th of June, 1857.

RECEIPTS during the half-year.	£	s.	d.

Mr. W. F. HOBBS drew attention to the loss sustained by the dinner of the Society at Salisbury.

Mr. RAYMOND BARKER said that a contract was made for the dinner for £200. The sale of tickets was conducted as usual, but very few persons seemed disposed to buy. Only £78 was received for tickets. It was, however, the most profitable dinner the Society had ever had, because it involved the least loss (a laugh).

After some remarks from Mr. MOORE and Mr. SLANEY, with reference to the annual dinners of the Society,

Mr. SAINSBURY said, he would take upon himself, as a Wiltshire farmer, to state that had the Council erected a pavilion at Salisbury they could have found the Wiltshire farmers flocking to it in a body, and it would, no doubt, have been well filled. The reason they did not go to the Council Chamber at Salisbury was that they considered that they had not been fairly treated in that respect—in fact, they took a little huff (a laugh).

Mr. Bullock Webster proposed, and Mr. Arkell seconded, a vote of thanks to the auditors, which was agreed to; Mr. Barker and Mr. Astbury were re-elected auditors; and Mr. Druce chosen as auditor in the room of Mr. Dyer, who retired from ill health.

Mr. MOORE then addressed the meeting at some length. He complained that the mode in which the accounts were presented to the members was not satisfactory, and suggested that a tabular statement should be prepared of the income and expenditure of the Society from the commencement, together with a statement of the number of members each year. He was anxious, he said, for the adoption of some plan by which the farmers in the different localities might be led to take greater interest in the meetings of the Society. So far as the *Journal* was concerned, he believed it was scarcely ever seen by the majority of the farmers, and that, when they did take it up, they soon put it down in despair. The articles were very valuable, no doubt, to the class of men who could read and understand them, and had produced beneficial effects on the agriculture of the country, but they did not bring home what was wanted to the minds of the agricultural community. By what means that was to be done he left to the consideration of the managers of the Society. In his opinion, too, the Smithfield Club ought to be amalgamated with this society, and the country meetings given up, substituting for them a great annual metropolitan meeting in the summer, and establishing district societies, comprising three or four counties, such district societies to be affiliations of the great central institution in London.

Col. CHALLONER said he rose for the purpose of answering some of the observations of Mr. Sidney, and he thought he should be able to show that the Council had not been quite so idle and so inattentive to the interests of the Society as some persons might suppose. Mr. Sidney had remarked that the number of members was at one period larger than it was at the present moment. Admitting that that was the case, he must observe that as regarded the class of members whom the Council were most anxious to secure, namely, tenant farmers and practical men, the list was never before so numerous as it was then. Soon after the formation of the Society, when members were elected, as it were, by acclamation, he had seen thirty or forty members put down their names all together at a country meeting. But what was the explanation of that? Why, that gentlemen could not attend the dinner without first becoming members. The result was that they used to be constantly writing ten or fifteen letters to persons for their subscriptions without getting any answer It was then quite common for a gentleman to say, "I subscribed at Southampton," or "at Liverpool," as the case might be; "but I am not a member of the society now, and I shall not pay any money." In fact, many hundreds of persons had their names struck off the books because they would not keep up their subscriptions. This was early in the history of the Society, up to the seventh or eighth years, perhaps, of its career. The Council were prepared to give, not only the gross number, but even the separate names of those who were struck off under those circumstances. Mr Sidney said that if they did so-and-so the number of members would be increased to 10,000. It might be so; but they liked to act upon something like certainty, and it was certain that within the last three or four years, or since the number of names was reduced, by the process of striking off, to three or four thousand, they had obtained an accession of a thousand additional and paying members, and he would add that there were less arrears in proportion among the farmers than among the governors. (Hear). It appeared to him that they could not have erred very much in the management of the Society, when the Society had been getting better known and more popular every year, and when there had been an accession of 1,000 paying members (Hear, hear). Again, Mr. Sidney had spoken of the necessity of giving notice of the lectures. He had papers there before him (*The Mark Lane Express*) from which it appeared that in all the reports issued by Mr. Hudson, the Council stated on what day Professor Way or Professor Simonds would deliver a lecture, and these announcements were always forwarded to the *Mark Lane Express*, the *Gardener's Chronicle*, and other agricultural journals; and when Professor Way was ill, there was a special advertisement to the effect that in consequence of his illness the lecture which had been announced would be postponed to a future day. With regard to the Bath and West of England Society, he must observe that it was no uncommon thing for children to outstrip their parents—(laughter)—and if this were the result of energy and vigorous management, it was a feather in the cap of the society in question rather than a reason for condemning the parent institution. With regard to the churns, trials had been made, but it was a very difficult matter. That was his department in the Exhibition of 1851, when he was for upwards of twelve hours in an atmosphere of 83 degrees. His report appeared in the Journal at that time, and since that period there had, he believed, been no very great variation in the different churns. That trial had subsequently proved to be a very correct one, because the same churn—the square American churn, making from 15lbs. to 20lbs. of butter—was found to be the best. With respect to the root-cutters and slicers, he might observe that at the Lincoln Show Mr. Moody brought out a turnip-cutter that was tried thoroughly, and he was so much pleased with it that he immediately bought one. He had procured three of them since, and every gentleman who had seen them at his place had pronounced them the best that they had met with. He would add that their consulting engineer, on being consulted the other day, recommended the Council to offer a reward for turnip-cutters, there not being one that he considered perfect. With regard to the election of the Council, he believed everyone knew that under the Charter of the Society, on a certain day in May the Council for the ensuing year had to be elected. Nothing could be better known than that at the General Meeting in May, the Council and trustees, and the officers of the Society, had to be elected by the members, the fact being made public, he believed, through the medium of all the agricultural papers. Mr. Moore had referred to the accounts. On that subject he would detain them only one minute. Let any gentleman present call for information under any one head of expenditure—be it the chemical grant, be it the veterinary grant, be it the country meetings, be it the establishment charges, he would undertake to find the information in a book which was before him.

Mr. MOORE said he did not for a moment question that the affairs of the Society had been managed in the most perfect manner possible. What he desired was, that a clear statement of the income and expenditure should be published half-yearly in the Journal.

Col. CHALLONER intimated that what Mr. Moore required had been done.

Mr. MOORE said, having examined the accounts published

from time to time, he must declare that he could not make out the annual receipts and expenditure. What he wanted was an account of the annual income and expenditure, with the number of members from year to year.

Col. CHALLONER said, the book before him, and to which he had just referred, was not got up for the occasion, but had existed from the earliest period in the society's career, and within five minutes he could point out the most trivial item in the accounts of any one year.

Mr. MOORE was afraid that his remarks had produced a wrong impression. What he meant to say was that the accounts published did not appear to him to furnish a fair criterion of the actual progress of the society from year to year.

Col. CHALLONER observed that there were arrears in every society, and that it was absolutely necessary to make out the accounts up to a certain day. He concluded by observing that as regarded the proposed alteration in the mode of conducting the society's operations, that was a question the decision of which must be left to the members as a body.

Mr. ASTBURY, as one of the auditors, felt it his duty to testify to the admirable manner in which the accounts of the Society were kept, and to the readiness with which they had been furnished with every possible information by Mr. Hudson.

Mr. BARROW, M.P., wished to correct an opinion that the Council were self-elected, and were elected for life Under the constitution of the Society, the Council were elected by the members generally. The Council naturally looked around among themselves, in the first instance, to ascertain who had been most useful, by attending the meetings and in other ways; a statement of the attendances was laid before the election took place: this was a guide as to the future. They were always prepared to listen to suggestions as to the election of a new member; and he had repeatedly heard it remarked that one gentleman should not be chosen because his county was fully represented, and that another should be chosen for the opposite reason. He was anxious that the members of the Society should have the election of the Council entirely in their own power, and that the right to nominate a new member should not be a mere shadow (Hear, hear). At the last election of the Council there were four-and-twenty members who might have been re-elected; and six of them were passed by, although they were men of high standing, simply because their attendance had not been satisfactory. With respect to the observations made as to the desirability of centralizing the meetings of the society, he must confess he was not particularly partial to the principle of centralization (Hear, hear); and he must say that he thought the travelling of the society from place to place had been beneficial to agriculturists generally. It was remarked that the large attendance at the shows was the result of excitement. He accepted that representation; and he said that if the country meetings led to excitement, there was reason to believe that that excitement produced good effects in the district (Hear, hear). An addition to the number of members in the particular locality was one consequence of holding a country meeting (Hear, hear). He was as desirous as those who had introduced the subject were, that the society should improve and progress, and the Council were happy to hear suggestions from gentlemen whom they had not had the pleasure of meeting at the Council Board.

Mr. SIDNEY wished to make two practical suggestions. Professor Way, it appeared, had resigned his office; and with all the respect which he entertained for that gentleman's scientific talents, he must say he was exceedingly glad that he had done so. It was absolutely necessary that if that society had a chemist, he should do something for his money. Professor Voelcker had been lecturing for the Bath and West of England Society in various towns; and in his case this had proved very useful. His lectures were on practical subjects; and owing to the manner in which these were brought home to the minds of those who heard them, the attendance of farmers had been very large, and the result very satisfactory. What he had to suggest on that subject was, that in filling the vacancy which had arisen the greatest care should be taken to select the most suitable person, and that arrangements should be made for securing a larger attendance of members.

Mr. BULLOCK WEBSTER, referring to the Chester Meeting, said he understood that Mr. Holt, the proprietor of Radley's Hotel, was prepared to erect the building at his own expense, provided he received sufficient encouragement from the Council. He would be glad to know whether the Council intended to hold out any special inducement to the inventors of steam-cultivators to send their inventions to the Chester Meeting? Many persons, he understood, were inclined to send them, but not entirely at their own expense.

The Rev. Mr. LINTON thought it very advantageous to hold meetings in the country. An opportunity was thus afforded to them of observing what implements were used in other districts besides their own; and he for one, had seldom gone away from a country meeting without having learnt something which he had afterwards found very useful to him in his own county—Huntingdonshire. The Journal had, he thought, been the means of diffusing an immense amount of agricultural knowledge throughout the kingdom. For example, in the very last Journal there was one of the most useful papers he had ever read in his life: he referred to the paper which described a very simple and economical mode of constructing roads on clay-farms, the author of which was Mr. Bailey Denton.

Lord FEVERSHAM then moved a vote of thanks to the Chairman. He did not see how any association of that kind, having practical objects in view, and aiming at practical results, could rest on its oars; and he was happy to say there was reason to believe that most of the members of the Council were in favour of progressive improvement (Hear, hear). He had himself proposed in the Council that the Show meetings should in future be held in the metropolis. He did not know whether or not Mr. Moore wished to have country meetings as well as London meetings.

Mr. MOORE said he would have three or four counties thrown into one, and have affiliated societies in different parts of the country.

Lord FEVERSHAM thought the Council would do well to consider whether it might not be an improvement to hold the meetings in London instead of in the country. Everything he heard with respect to the railways, with respect to the want of accommodation in towns, and with respect to the inconvenience sustained by exhibitors in consequence of having to send their stock to distant parts of the kingdom, convinced him that this view was correct. He was opposed to the amalgamation of the society with the Smithfield Club. He would keep both societies distinct, but would have a large building erected for the meetings of both societies—one in the summer and the other in the winter. His lordship concluded by expressing his dissent from the opinion that the judges should be required to give reasons for their decisions, observing that such an arrangement would lead to great practical inconvenience, while it could produce no useful result.

Mr. HOBBS, in seconding the motion, said he was pleased to find that the members of the society were beginning to take an interest in its proceedings, because he felt satisfied that unless the Council knew what a strong feeling prevailed among the members, the measures which were so desirable for the success of the society would never be carried out. He trusted that during their noble President's year of office necessary reforms would be effected.

The motion having been carried by acclamation,

The CHAIRMAN, in replying, said he rejoiced at the observations which were made at the commencement of the meeting, because they had elicited the remarks of Col. Challoner, who was a member of the Finance Committee. He was one of those who thought that there could not be too much publicity as regarded the accounts, and that the entire management of the society could not be too thoroughly ventilated (Hear, hear). It was on that principle that he had always acted in relation to his own farming operations, being convinced that it was the best mode of eliciting the truth and promoting improvement. He could not agree with his noble friend, Lord Feversham, that it was desirable entirely to do away with the migratory proceedings of the society, because in counties which had been most behindhand in agriculture, he had seen not merely excitement for a time, but very great permanent improvements as the result of the country meetings. He admitted, however, that the holding of a meeting occasionally in London would be advantageous to agriculture, and he should be glad, so far, if his noble friend's suggestion could be carried out.

The meeting then separated.

THE LONDON, OR CENTRAL FARMERS' CLUB.

THE ANNUAL DINNER.

The annual dinner took place on the Tuesday evening in the Smithfield Show week, at Radley's Hotel, under the presidency of the chairman of the year, Mr. Owen Wallis. Among those present on this occasion were: Mr. R. Baker (of Writtle), Mr. W. Bennett, Mr. Mechi, Mr. Cuthbert Johnson, Mr. Trethewy, Mr. Wilmot, Mr. Bullock Webster, Mr. Bell, Mr. C. Stokes, Mr. Parkinson, Mr. Coussmaker, Mr. Skelton, Mr. J. Wood (Sussex), Mr. E. Pope, Mr. C. Howard, Mr. J. Druce, Mr. Molyneux, Mr. J. H. Johnson, Mr. Hammond, Mr. Goldhurst, Mr. H. Cheffins, Mr. W. Cheffins, Mr. Tuxford, Mr. Purser, Mr. Pile, Mr. Cutts, Mr. Congreve, Mr. Ward, Mr. Reeve, &c., &c. Mr. Thomas, of Bletsoe, occupied the vice-chair.

After the dinner, which was furnished by the landlord, Mr. Holt, in excellent style,

The CHAIRMAN proposed "The Queen," observing that the throne of England was never occupied by a sovereign who had greater claims to the affection of her subjects.

After a heartily-loyal response to the toast,

The CHAIRMAN said, the next toast was "The Prince Consort, the Prince of Wales, and the rest of the Royal Family." The first of these exalted individuals had been distinguished ever since he had been amongst them as the patron of the arts and sciences, and had done all he could to promote the social and intellectual welfare of his fellow-beings. He was also, as they were aware, a great patron of agriculture. Of the Prince of Wales they at present knew but little, but they induced a hope that he would profit by the example of his illustrious parents, and would prove at some distant day a fit successor to his Royal mother. While the cause of the arts and sciences was well represented by the Prince Consort, the cause of the army and of the national defences was equally well represented by another member of the Royal family, the Duke of Cambridge, who by his speeches on various public occasions had shown that he was as much to be admired for his sound, practical, good sense and his kindness of heart, as they all knew that he was for his daring courage and intrepidity in the presence of an enemy (cheers).

After a due response to this toast,

The CHAIRMAN proposed "The Army and Navy." He said when that toast was proposed three years ago, their gallant soldiers had just won for themselves imperishable fame at the battles of the Alma and Inkermann, and now they had fresh claims to our admiration, arising from the fortitude with which they had undergone sufferings and privations ten times more fatal than the bullets or the bayonets, the shot or the shell, of the Russians (cheers). The army, which had before so much cause for just pride, had recently performed acts of the greatest intrepidity and daring in suppressing the mutiny of the treacherous Bengal sepoys; and though universally outnumbered, they had on all occasions come off the victors. The names and deeds of Havelock and his devoted companions would continue in the recollection of a grateful country. Well might they indulge a hope that Havelock and his forces would be rescued from the perilous position in which they were when last heard of, and that the gallant general would live to reap the reward and enjoy the honours conferred upon him (cheers).

The toast was drunk with the greatest enthusiasm.

The CHAIRMAN afterwards said, the toast which he was about to propose was undoubtedly the toast of the evening, for it was "Success to the Central Farmers' Club" (cheers). It had been customary on that and similar occasions to review their past proceedings, and to examine the present state and future prospects of the club; and whether they looked at the past, the present, or the future, he thought that at no period of its existence had it been in so good a position as at that moment. Three or four years ago it was thought that the club would be broken up. Indeed its downfall was very commonly predicted. He, for one, never paid much attention to these predictions, believing that the club was of so useful and valuable a character that it would ultimately receive that amount of support from the farmers of England to which the objects it had in view so well entitled it. The Royal Agricultural Society brought before them the best specimens of breeding stock, and the implements which were best suited to the increasing wants of the farmer. On the other hand, the Smithfield Club, and other societies of a similar nature, brought before their notice the best specimens of fat animals. But in a society like the Central Farmers' Club, the farmers of England could meet together, and learn how breeding-stock might be best reared; how fattening stock might be best fed; what implements were best suited to their purposes in their respective localities; what manure was most advantageous for a particular crop—how it could be best prepared, and how best applied; how the soil could be most economically and effectually drained; how land which had hitherto been in a state of waste could be brought under successful and profitable cultivation; and last, though not least, how the labourers of England could be best educated, so as to suit the altered circumstances of themselves and their employers (cheers). It was, he said, in societies like that, that farmers met together to learn from each other, by discussing subjects of that nature; and those who from a false economy stayed at home, or took no notice of the matter, would ultimately find themselves distanced in the race which they were all running (Hear, hear). So far from having to mourn over the downfall of the club, they had to rejoice in its daily increasing prosperity. During the year which was now closing, they had elected very nearly the same number of members that they had in two preceding years — by far the three best years the club ever enjoyed—and concurrent with this augmentation in its numbers, the club had greatly increased in reputation and in the estimation of the public. This was manifest from the value of the discussions which had taken place during the past year, and the position and character of the gentlemen by whom they were introduced. Moreover, their financial position also exhibited a great improvement; for instead of their being in debt, as they were some years ago—if they were not in debt at that period, their income was not equal to their expenditure—that state of things was now reversed, and they were actually saving money at the rate of about £50 a year (cheers). He thought he was safe, therefore, in affirming that the prospects of the club were more flourishing than they had been at any previous time during its career. He now called upon them to drink "Success to the Club;" and he would couple with the toast the name of Mr. Baker, of Writtle.

After a fitting response to this toast,

Mr. BAKER said he felt that he was very highly complimented in being selected to return thanks for this toast, more especially as his name had been connected with the toast by their excellent chairman, Mr. Wallis. He was quite sure that the club was very much indebted to that gentleman for the manner in which he had presided over its proceedings; and no one could be otherwise than satisfied with the progress it had made under his superintendence. He hoped he should be excused if he spoke for a moment of himself in connection with the club (Hear, hear). He was one of the first originators of the club; He had been an attentive promoter of its interests from the commencement, and he hoped he should continue so to the end. He saw it in its first infancy, winding along its tortuous way, "dragging its slow length along;" he now rejoiced to see it in its maturity, occupying a position superior to that of any similar institution of the kind in the country (cheers). And how were they to account for this? How were they to explain the fact that that club now formed one of the leading agricultural features of this country; and that, though it did not perhaps occupy so elevated a position as the Royal Agricultural Society, but one of a secondary nature, yet it bene-

fited a larger number of persons than even that society itself? If it were an honour to be connected with any leading society of the country, more especially did he feel it to be an honour to be connected with a society which was so closely connected with agriculture. Of agriculture, indeed, he had always been one of the warmest advocates, and he might say of her in the words of the poet Burns—

"She found me at the plough,
And cast her inspiring mantle over me."

He was sure that the most pleasurable part of his life had been spent in the pursuit of agriculture; whether or not his efforts as an agriculturist had proved beneficial to others as well as himself, he must leave it to others to decide. The great object of that society was, like that of the Royal Agricultural Society, to blend science with practice. With this view they had had scientific lectures bearing upon agriculture. How the subjects introduced were treated, it was not necessary for him to state; nor need he remind them how a subject of great importance was treated on the previous evening by a very able member of the club, or of the valuable discussion which followed (Hear, hear). For his own part, he must confess that he had derived very great benefit from the club. He had obtained much information there, which he probably would never have obtained elsewhere (Hear, hear); and, more than that, he had been brought into association with many of the leading agriculturists belonging to different parts of the kingdom. Formerly farmers used to live constantly on their farms, and were hardly ever brought in contact with persons of their own pursuit in other districts; and the associations which that club had produced among the leading cultivators of land was certainly not one of the smallest benefits conferred by it on the agricultural community (Hear, hear). In that club farmers were brought to know each other; each member communicated any important information which he possessed for the benefit of the whole, and by means of the press that information was disseminated throughout the whole of England. He thought, therefore, it might be said that the Central Farmers' club had done its duty, and fulfilled the expectations which were raised with regard to it at the time of its formation. (Hear, hear.) It was as one of the oldest members of the club that he had been selected to respond to the toast. He now called upon them to look forward to its increasing usefulness, more especially in connection with the various political or financial events which might hereafter affect the interests of agriculture. There had of late, as they were all aware, been a great prostration of the monetary interests of the country. It was not to be supposed for a moment that that did not concern them. (Hear, hear.) He believed there was no class of persons in the kingdom who were more affected by the money-laws than farmers were; and, although the question might appear to some present an abstract one, it appeared to him that they ought, as a body, to watch the proceedings of Parliament, and to give their best attention to a matter in which their interests were so clearly involved. (Hear, hear.) They would all, no doubt, be very much surprised and alarmed if it were enacted by the Legislature that the bushel, instead of holding four pecks, should hold five, and that they should still sell at the same price that they did before; they would all, of course, regard that as a robbery of them to the extent of twenty per cent. of their property in corn. That was exactly what was done, however, by the money-laws; and they might depend upon it that, without some change in this state of the law, an act which worked as the present one did would be set aside from time to time whenever it was considered necessary to suspend its operation. The present law was not based on honest and just principles. There were a number of individuals who reaped their harvest at the farmers' expense; and when times of pressure occurred, and a large rate of interest was being exacted from mercantile houses which were in a state of difficulty and dismay, the Government, under the pretence of stopping the evil, stepped in and suspended a law which was not based on a proper foundation. He felt that he was now touching on a question of which he was not master; he had, however, studied the law in some of its bearings; he had foretold some of its consequences, and he would predict that, unless some remedy were applied, farmers would be still more seriously affected even than they had been. As there was a gentleman present who had made the monetary system his special study—he referred to Mr. Bell—he hoped that gentleman would favour them with his views on the subject: more especially as regarded the bearing of the existing state of things on agriculture. In conclusion, he would remark that agriculture, as now carried on in this country, might justly be regarded as a science; and it was as a science as well as an art that it was being carried on, and its present position was not only the strength of our own country, but the admiration of all surrounding nations (cheers). He thanked them most sincerely for the manner in which they had received the toast.

Mr. Trethewey said he rose to propose a toast which he was sure would be well received—it was the health of their excellent Chairman (cheers). In doing so, he felt that the task entrusted to him was, in fact, a very easy one. They had all heard a good deal, of late, about putting the right man in the right place; and he thought they could not possibly have a better illustration of that maxim than they had in the case of their present Chairman. If he were merely addressing the committee, or if he were addressing only those members of the club who were in the habit of attending the monthly discussions, he should feel that it was unnecessary for him to say anything in reference to the merits of Mr. Wallis; but on looking round the room he saw a great many gentlemen who had not had an opportunity of meeting the Chairman of the club, and therefore he hoped he should not be considered tedious if he showed how fortunate the club was in having so good a president. That evening was the last occasion on which Mr. Wallis would have to preside over them that year. Another gentleman would fill the chair; and he earnestly hoped that, when Mr. Wallis's successor quitted office, the club would be as prosperous as it was then (Hear, hear). He had said, in effect, that they had the right man in the right place; and if any arguments were necessary to prove that, there could be no difficulty in bringing it forward. He conceived that, for the chairmanship of a farmers' club, it was necessary to have a practical farmer, or, if not a practical farmer, at least some one who had identified himself with the cultivation of the land, and took a deep interest in agriculture. Now in their present chairman they had a practical farmer (Hear, hear)—a farmer occupying a very large amount of land, and one whom his neighbours regarded as one of the best specimens of their class. "Depend upon it," one of those neighbours said to him that day—"depend upon it, whatever Mr. Wallis undertakes to do, he will do well" (Hear, hear). Not only had they the testimony of his neighbours in his favour, but his name was to be found among the list of the judges of the Royal Agricultural Society; and he really did not know a more honourable position than that. He felt that he had said quite enough in proposing the toast; and congratulating the members on the improved prospects of the club, he now left it in their hands.

After the toast had been drunk in the most cordial manner—

The Chairman said he could not adequately express his thanks for the very handsome manner in which the toast had been proposed and received. He felt that he was quite unworthy of what had been said with regard to him by Mr. Trethewy. He had, however, endeavoured to do his duty during the past year, and he felt greatly indebted to the members for the courtesy which he had met with on all occasions. He was confident that there were many gentlemen who would have filled his position with much more ability and with much greater advantage to the club than he had done (No, no). When, however, they did him the honour to nominate him, he felt bound to obey the call, and he should retire from the chair with the feeling that he could never forget the kindness which he had always experienced. He valued this club very highly indeed, on account of the many valuable friendships which he had formed in connection with it, and he should endeavour to support it as long as he lived. He would conclude by drinking to the good health of all present (cheers).

Mr. Bullock Webster said he had been entrusted with a toast, which he felt great pleasure in proposing, namely, "The Royal Agricultural Society of England" (cheers). That society had now very great difficulties to encounter. Formerly it was very easy for the council to dispose of the routine sort of business, which constituted the bulk of their proceedings; but the case was very different in the present day. There were now no less than five or six different descriptions of the steam cultivator brought under their notice, upon the compa-

rative merits of which they had to adjudicate. He might here observe that the gentleman who sat on his right (Mr. Halkett) had invented a new steam cultivator, which he was about to bring before the Agricultural Society, and which he was prepared to prove would perform the following operations at the following cost:—Ploughing, 1s. 7d. per acre; scarifying, 8d.; harrowing and rolling, 5d.; hoeing, 3d.; reaping, cutting, and delivering, 10d.; surface water, 1s. 2d.; carriage of manure and distributing, 1d. That was of course when the preparatory expenses in laying down the rails, &c., had been defrayed. It would require a good deal of the time and attention of the Council of the Royal Agricultural Society to investigate this matter, and he thought that was an additional reason why the society should be supported by farmers. Mr. Halkett prepared for the work of ploughing by placing rails on the surface of the land; and he must say that when so many thousands of pounds were spent in preparing to launch the "Leviathan," farmers should not grudge a guinea a-year to a society which undertook the task of ascertaining the merits of an invention, the object of which was to enable them to perform the operations of the farm in the shortest time and at the least expense (Hear, hear). He trusted that those farmers who had hitherto done nothing for the Royal Agricultural Society beyond drinking success to it would now be induced to come forward with their annual subscription (Hear, hear).

The toast having been duly honoured,

Mr. W. BENNETT rose to respond. He said no one could feel more deeply indebted to the Royal Agricultural Society than he did. The society had been established about twenty years, and no one could be ignorant of the great benefit which had been conferred on the country by its proceedings. Agriculture had made such rapid progress during that period, that it might be said, as was remarked by Sir James Graham a short time ago, to have climbed almost every hill top, to have given fertility to barrenness, and changed the whole face of the country. (Hear, hear.) If a tract of land were now uncultivated, or not cultivated properly, it was quite an exception to the rule. In his native county, to which his attention was of course more particularly directed, he had lately taken a review of what had been done in the last forty years; and he had been exceedingly struck with the extraordinary progress which agriculture had made there. He had no doubt that for this improvement it was in a great degree indebted to the Royal Agricultural Society. It was the fashion to speak contemptuously of the practice of offering rewards to agricultural labourers for superior skill in ploughing; but, in his opinion, it was a great advantage to the community to encourage emulation among the labourers, in order that whatever they did might be done in the best possible manner. (Hear, hear.) It was a good maxim that "whatever was worth doing at all was worth doing well," and that maxim was as applicable to the daily operations of the farm as to any other branch of labour. (Hear, hear.) He had observed that if a labourer contracted a habit of doing things in a slovenly manner early in life, he hardly ever became a good labourer afterwards; and it was of great importance, therefore, that efforts should be made to excite a spirit of emulation among all who were employed on the farm. The Royal Agricultural Society had in that way been very useful to agriculture; and it was remarkable that in the counties where that society was best supported would almost invariably be found the best farming (Hear, hear). The society had been of great service in encouraging the best breeds of animals—those breeds which it would pay best to rear and to fatten. It had also done much to improve agricultural machinery. It was indeed astonishing what had been done in that department within the last fifteen or twenty years, and he fully expected that still greater results would follow if the society were supported in a proper manner. No man could predict what would yet be done by means of steam (Hear, hear); but he must say that he thought Mr. Webster was rather pulling the long bow when he spoke with such confidence of the ploughing of land at 1s. 7d. per acre (laughter). It reminded him of something that was said to him on an occasion when he was about to give evidence in reference to some agricultural topic. A noble lord who had been at the bar advised him beforehand to be careful not to put the matter too strongly, observing that when he was at the bar he never felt so sure of losing his cause as when his witnesses were ready to swear anything (laughter). He (Mr. Bennett) had always remembered that caution in similar cases. It was an important maxim that men never did themselves so much injury as when they put their case so strongly that no one believed it (laughter). He hoped he should not be misunderstood. He admitted that no one could fix a limit to the extent to which steam might be applied to the cultivation of the soil; but still he would recommend his friend, Mr. Webster, not to put the case of Mr. Halkett again quite so strongly as he had done (Hear, hear). Before sitting down he had to propose a toast, which he was sure would be well received by all present; it was "Success to the Smithfield Club" That society was the handmaid of the Royal Agricultural Society, and its operations had been exceedingly useful. They all knew that it had, like many other institutions, been a good deal abused. It had been said, for example, that the Smithfield Club encouraged the feeding of animals to such a pitch that no one could eat them. It might happen that a fashionable and delicate young lady would sometimes find on her plate a piece of beef that was too fat for her, and might turn up her nose at it; but it did not follow that good fat beef was not a good thing for the community at large. Moreover, it had to be borne in mind that the great object of the Smithfield Club was to determine the question what kinds of animals it would pay best to rear and fatten for the market. He believed that that club had within the last fifty years conferred immense benefit on this country. Why was it that England stood before all the rest of the world as regarded the quality of its animals? Why was it that, as regarded the growing and fattening of animals, no other country came near our own? It was because practical, business-like men had devoted their attention to the subject for a great number of years, and offered rewards for the best animals that were brought to London. Let the *Times* or any other great leviathan of the press say what it would on this subject, they must still strive to go ahead, they must still endeavour to improve the breed of stock, and he was confident that they would thus effectually promote both their own interest and that of the community at large. He would now propose "Success to the Smithfield Club!"

Mr. C. STOKES said, as an old member of the Smithfield Club, he felt great pleasure in rising to return thanks. Thirty years ago, he remembered when the Duke of Bedford withdrew his premium, this club was very near being broken up. Had it not been for a few spirited farmers at that time, it must certainly have become extinct; and he might leave it to any one who had that day visited the noble exhibition in Baker-street to say how great a loss that would have been. (Hear, hear.) No one could look at the Devons, the Herefords, and some of the Shorthorns; or examine the Long-woolled sheep, the Leicesters, and the Southdowns, without being gratified at the great improvement which had taken place within the last few years. It should be remembered that the Smithfield Club had been a pioneer to all the other societies having similar objects, and that but for it the various local associations would, probably, never have existed. (Hear, hear.) Its influence had been felt not only in this country, but even in France, where there had been periodical exhibitions of stock for the last five or six years. Moreover, the Smithfield Club might claim the honour of having produced the Royal Agricultural Society. Lord Spencer and the Duke of Richmond mentioned their intention of forming the Royal Agricultural Society to the members of the Smithfield Club, and Lord Spencer afterwards declared that it was the cheers with which the British farmers received the proposal, that encouraged them to proceed. No club in the kingdom, he believed, now rested on a surer foundation than the Smithfield Club. Their funds were in a most flourishing state. They had plenty of money to give away, and plenty of money to put by (cheers).

Mr. WILMOT said he had been called upon to propose the next toast, which was "The Committee of Management." He thought the best thing that he could do, in proposing that toast, was to refer to the report just issued, which showed an increasing number of subscribers, and an increase of the funds (cheers). If that state of things continued, the club must go on and prosper. He begged to couple with the toast the name of Mr. Wood, of Ockley.

Mr. WOOD, in replying on behalf of the Committee congratulated the assembly on the fact stated in the report

just issued—that 74 new members had been elected during the last year. It would be wrong to take credit on behalf of the Committee of the year for that increase; for the circulars which were sent round the country, with the able assistance of the Secretary, informing farmers generally that there was such an institution as a Central Farmers' Club, and setting forth its claims to the support of tenant-farmers—those circulars, he said, were issued by a previous committee. It had been already observed, that the subjects discussed had usually been very well introduced. He thought most persons would agree with him that the list of subjects for the past year had been more than ordinarily interesting; but, at the same time, he hoped the list for the ensuing year would be equally interesting and equally useful. There was one subject which to his mind appeared extremely interesting, and which he should be exceedingly glad to see brought forward. It had, indeed, already been introduced on one occasion; but it was done by a very incompetent individual—namely, himself (laughter). [Mr. Wood was understood to refer to the currency question; but he did not specify the topic to which he alluded.] On that subject he entertained very decided opinions; and he hoped it would be again introduced, by some gentleman who was competent to deal with it. It certainly could not be too well understood by the agricultural community.

Mr. BELL, responding to the appeal made to him by Mr. Baker, made an elaborate statement of his views on the currency laws, condemning the monopoly which, he contended, was practcally established, under the present system, in favour of capitalists as opposed to producers, whether agricultural or manufacturing, and referring to the suspension of the Bank Act of 1844 as a proof that the system required alteration. He concluded by proposing the health of the vice-chairman, Mr. Thomas, of Bletsoe, which was very cordially received.

Mr. THOMAS briefly returned thanks.

Mr. MECHI said he had been requested to propose "The Local Farmers' Clubs," in connection with the name of Mr. Pile, of Winchester. The remarks of the Chairman with regard to the Central Farmers' Club were applicable to farmers' clubs generally. If remaining always at home and never associating with farmers belonging to other parts of the country tended to perpetuate prejudice and obstruct improvement, still more must that be the case if farmers did not associate together in their several localities. One of the chief advantages of local clubs was that they enabled farmers to test the merits of their labourers in the field. He would not broach the delicate question of giving rewards for good conduct, because that was a question which was open to difference of opinion; but he must say that when a labourer who thought himself a capital ploughman found himself the worst ploughman among the competitors, that result was likely to take a little of the conceit out of him, and make him more humble and deferential in future. The same remark applied to farmers who competed for premiums for the best farms. Moreover, farmers' clubs tended to strengthen the social position of farmers in this country, and there could be no doubt that their association was in various ways a great mutual advantage. With regard to the prospects of agriculture, he agreed with preceding speakers that they had to look forward to important changes. Great improvements had doubtless been made in their own time, but it must prepare their minds for still greater ones. They had already got rid of the flail, which cost a shilling, and substituted for it a costly machine, because it did the work cheaper; and it remained to be seen whether or not that enormous power which clothed the world could not be substituted for the existing plough. Mr. Halkett, who had undertaken this task, was a man of great intelligence; and having gone the other day to see his machine at work, he must declare his satisfaction at what he witnessed. As regarded the expense, he did not think Mr. Bullock Webster was quite correct in stating the cost of ploughing at 1s. 7d. per acre, as that did not include the interest of money expended on the rail (Hear, hear). He supposed that was additioual.

Mr. HALKETT: Yes.

Mr. MECHI continued: If the invention were adopted, the power of keeping "these horses" at work night and day would be an enormous advantage. He was happy to find that Mr. Halkett was going to explain his views on the following evening. The question at issue seemed to hinge on the practicability of using steam-power without encountering too much friction, and he hoped that queation would now receive a satisfactory solution.

Mr. PILE, in replying, alluded to the efforts which were being made in his own neighbourhood to improve the condition of labourers. Besides the ordinary means, a society with which he was connected was endeavouring to promote that object by means of cottagers' shows. In order to make the labourers in the neighbourhood better gardeners they gave rewards for the best garden productions. They also bestowed premiums on the wives who were the best managers. The society had only been in existence two years, and there was already visible and material improvement.

The Rev. Mr. JAMES, on rising to propose the next toast, said, having had a glimpse of the list of toasts, he regretted to find that the honest and hard-working agricultural labourers were not included. He had no doubt that that omission was an inadvertent one, and would be supplied. (Hear, hear.) The toast which he had himself to propose was, "The Agricultural Press," coupled with the name of a man, whom to know was to esteem—he meant Mr. Tuxford. (Cheers.) He would say of that gentleman that his principles of action always appeared to be the same.

Mr. TUXFORD felt very much indebted to all present for the kind manner in which they had been pleased to receive his name in connection with the agricultural press of this country. He did not know that any man could fill a prouder position than the one in which he was required faithfully, conscientiously, and independently to discharge such functions as had fallen to his own lot (hear, hear). Still perhaps there was no office with duties of a more onerous character attached to it. (Hear, hear). You had to speak independently of all men, regardless of any crochets or any peculiar views which they might entertain, and even at the risk of giving them offence. You had to speak the truth on all topics without considering the consequences which might befal you in the discharge of your duty. Now, when such was the case, the recollection of the kindness evinced towards himself that night would be a source of satisfaction to him through life (hear, hear). But if ever the press of this country should be actuated by sinister motives, or led by anything else than a sense of rectitude, it would forget the nature of its office, and descend from the high position it had now attained (hear, hear). He would now supply the omission mentioned by Mr. James—and in doing so he thoroughly agreed with him could only have been an oversight—by proposing "The Agricultural Labourers," and he was quite sure there was not a person present by whom that toast would not be received with as much enthusiasm as any preceding one (cheers). He was glad that so much attention was now being devoted to the education of agricultural labourers. There was a period when the plough constituted almost the only implement on the farm. That time had now happily passed away—a very different state of things existed—and if they wished to cultivate their farms on the best principles, they should take care to educate the labourers, so as to prepare them to properly fulfil their duties, instead of injuring, from their want of knowledge, the new machinery which was now being brought to bear on agriculture (hear, hear).

The toast was drunk with enthusiasm.

Mr. W. SHAW proposed "The Secretary," observing that it was the united testimony of all who had had the means of forming an opinion, that no man could possibly discharge the duties of the office better than they were discharged by Mr. Corbet (cheers).

The toast was very warmly received; but Mr. Corbet having retired shortly before, was of course unable to reply.

The concluding toast was "The Visitors," coupled with the name of Mr. Halkett, and to which that gentleman replied at some length on the subject of steam power, and his own invention.

The company then separated.

EXTRAORDINARY AGRICULTURAL CASE.—At the Aylesbury County Court, on Friday, Nov. 20th, an important case was heard, and the facts involved the point whether the owners of bulls are permitted to turn them out without taking proper care that they could not break through the fences

and herd with other graziers' stock. The plaintiff was Mr. Senior, of Broughton hall, near Aylesbury, a magistrate for the county, and a well-known grazier; the defendant being Mr. Self, the manager of the London and County Bank at Aylesbury. The action was brought to recover the sum of £19 19s., for damages from the negligence of the defendant. It was alleged that the plaintiff had, at great trouble, secured a pure breed of Devons, which were depasturing in a field adjoining Mr. Self's grounds, in which was a bull, which trespassed on the plaintiff's grounds, and associated with his stock; in consequence of which the plaintiff said a most valuable heifer, the produce of the bull which had won the prize at Norwich, and had never been beaten, and a cow which he had bought of Lord Macclesfield, was in calf. He (plaintiff) said it was important that his stock should remain pure. He said he was offered 30 guineas for the produce of the heifer which was the cause of the action; but owing to Mr. Self's bull having comt mitted the trespass, he sold the heifer and calf (which ought to have been worth £40) for £17 10s. The witnesses stated that Mr. Self's fences were very bad. Mr. G. L. Brown, barrister, for the defence, contended that the case had nothing to do with the breeding of cattle, but was merely a little bit of private quarrelling. It was said that there was an assumed likeness between the calf and his suspected sire; but there was no daguerreotype, and of course no likeness could be proved. He contended, therefore, that there was no proof that the plaintiff had sustained damage at the defendant's hands. He called upon the jury to give the plaintiff the smallest conceivable coin in full satisfaction for any conceivable injury he had sustained. Various witnesses, including Mr. Gadsden, the extensive auctioneer and valuer, and Mr. H. Phillips, the well-known dealer of Thame, were called on the part of the defendant; and they swore that there was nothing extraordinary in the breed of the plaintiff's stock, and that the heifer and calf were not worth more than £17 or £18. Other witnesses swore (in opposition to what had been urged on the part of the plaintiff) that the defendant's fences were in good condition. His Honour, Mr. C. Temple, summed up at great length. The jury retired, and, after being absent about half-an-hour, found a verdict for the plaintiff—damages 1s. Immediately the verdict was announced, the court, which was densely crowded throughout the whole five hours the case lasted, rang with a shout the like of which has never, perhaps, been uttered there on any such occasion. It was, however, of course, suppressed by the officers and the judge.

ROMAINE'S CANADIAN STEAM CULTIVATOR.

TO THE EDITOR OF THE ENGINEER.

SIR,—Certain errors having been, inadvertently or otherwise, promulgated respecting the above invention, calculated to depreciate the efficiency of the "Cultivator," and to detract the honour of the invention from the rightful and sole inventor, we shall feel obliged if you will give prominency in your journal to the following remarks in order that the public may be rightly informed on the subject.

A writer in the *Illustrated London News* of Oct. 3rd, 1857, whilst strongly commending the invention, makes the following delusive remark:

"Crosskill's Romaine Cultivator.—We give an illustration of the new steam-cultivator, invented by Mr. Robert Romaine, a Canadian; improved and manufactured by Messrs. Crosskill, the eminent agricultural implement makers, of Beverley, Yorkshire, whose name is so well known in connection with the clod-crusher. .... Crosskill's Romaine steam cultivator differs from all others hitherto brought before the public, in entirely dispensing with ropes, &c."

In reference to the above paragraph, we deem it necessary to state that Mr. Robert Romaine, of Peterborough, Canada, but now residing at Beverley, in Yorkshire, is the sole and entire inventor, and that the whole of the improvements that have been made in it have been effected by himself, and not by another party, as therein implied; and further, that the machines are manufactured by the trustees of the Beverley Iron Works, from Mr. Romaine's own suggestions and improvements.

In the same paper of the same date it is subsequently affirmed that Mr. Romaine sent one of his machines (the second that was built) to the "Great Exhibition of Paris in 1855, where the inventor, Mr. Romaine, was one of the Canadian commissioners. This machine, like Mr. Mechi's, was to be drawn by a pair of horses, the steam power being employed in turning the cultivator. In Paris Mr. W. Crosskill saw it, and thought so well of it that he took it up, and the firm have spent two years and some thousand pounds in bringing it to its present state of efficiency. The third machine would not steer or travel, until the wheel arrangements had been changed to the present form and proportions."

With regard to the above statement, which is decidedly and injuriously incorrect, it is necessary to state that the second machine, which was intended for the Exhibition at Paris in 1855, worked on the plains of St. Denis during the summer, and tilled the land. As well as the present one it was not drawn by horses, but propelled itself over the land by steam-power, being only deficient in its boiler and steering apparatus. The third machine, being the first built by the trustees of the Beverley Iron Works, was perfect in its steering apparatus, and travelled equally as well as the present one. The statement that the firm have spent some thousand pounds in bringing it to its perfection requires no answer, as the trustees of the iron works are alone the responsible manufacturers.

The same errors have been fallen into or communicated to a writer in *Bell's Messenger*, of September 21st, 1857, in which paper it is stated: "Romaine and Crosskill's steam cultivator.—On Friday, the 11th instant, Messrs. Crosskill broke the silence they have so long maintained as to the steam cultivator, which they entered but did not produce at Chelmsford and at Salisbury."

The claim Mr. Romaine enforces as the sole inventor and improver of the machine, as stated before, is a satisfactory reply to the mistakes disseminated by such an incorrect version of the invention. In the same article it is afterwards stated: "The patentees estimate that it (the machine) can do nearly an acre an hour, and work at night as well as day."

In reference to this quotation, we beg to say that Mr. Romaine has the sole credit of the patent, and with him alone is vested the power of granting licenses for its manufacture. The writer in the same paper afterwards adds—"At that time (that is during the Paris Exhibition) it could not steer, and could not work without breaking down."

It will be observed that the writers in the *London News* as well as in *Bell's Messenger*—probably one and the same party—have fallen into the same error, and made the same misstatement. As the repetition of these mistakes and erroneous representations in other papers might prove both prejudicial to the inventor and the invention, we trust you will do justice to both, as well as to the manufacturers and the public, by giving insertion in your journal to these very necessary corrections. R. ROMAINE, and T. E. TURNER,

(for the Trustees of the Beverley Iron Works).

Beverley, Nov. 13th, 1857.

ALUM IN BREAD.

SIR,—More alarm may perhaps have been excited upon this subject than it requires; for when used with sound flour, merely to whiten the bread, and in quantity not exceeding 1 oz. to the bushel of flour, it would not be likely much to affect a healthy stomach. But even then it is an illegal and dishonest practice, and might hurt weak digestions; and when used in arger quantity, with unsound flour to give it the appearance of sound, the unsoundness of the flour and the increased quantity of alum are likely to be very injurious in daily use, particularly to the aged and infirm poor who have little or no other strengthening diet. And this is probably the way in which most of it is used.

The precise detection of the alum is a nice point.

But there has just been suggested a simple method of discovering it, not only easy but rather amusing. Many housekeepers are aware that logwood strikes a purple dye with alum, but not so evidently without; so, if we put a slice of bread into a solution of logwood, and let it soak three or four hours, and then take it out, if it contains alum it will have taken the purple dye, but not otherwise. Making

therefore a logwood solution, by boiling a few chips of logwood in a good pint of soft water in a pipkin or skillet (not iron), till the liquid becomes a deep orange colour that one can just see through, straining it off, letting it cool in a basin, then putting in a slice of bread without crust, between a quarter and half an inch thick, letting it digest two or three hours, and then taking out the bread and breaking it; if it contains alum it will be dyed purple, more or less through (not merely on the surface), except the bread is very sour, which will prevent the dye from changing colour: or, on the other hand, when the baker or miller has put in *too much soda* to correct the sourness, in which case it will turn purple (liquor and all) without alum, so that it is not quite certain; though if bread which is *not sour* takes no purple dye, it may generally be regarded as free from alum, and when it does take the purple it is likely to be alumy or otherwise unsound, and if needful should be submitted to chemical examination.

J. PRIDEAUX.

P.S. I am obliged to your correspondent for the complete information respecting "till-seed." It is odd enough that the English translator should have gone to India for a name so well-known as Sesamum or Sesame, at least from the first translation of the "Arabian Nights' Entertainments."

ROYAL DUBLIN SOCIETY WINTER EXHIBITION OF FARM PRODUCE.

Those who have had an opportunity of visiting the Christmas shows of the Smithfield (London) Farmers' Club, for the last few years, have been delighted and instructed with the extraordinary specimens of mangel-wurzel and other crops from Ireland. Without drawing any invidious distinction between English and Irish farming, it must be confessed that so far the Emerald Isle has yielded larger roots than has been produced on British soil. Whence arises this superiority? There is much in the climate of Ireland; but we believe that the chief cause lies in the stimulus given to Irish agriculturists by intercourse with those English and Scotch farmers who have made Ireland the land of their choice. If this supposition be correct,—and it is the opinion of many Englishmen of our acquaintance,—what an apt illustration the circumstance affords of the importance of having our own experience whetted occasionally by intercourse with others—by an occasional run by "rail and road," to see a cattle show, or the farm of some eminent agriculturist.

With these introductory observations, we proceed to give a brief notice of the exhibition of farm produce opened on Limton Lawn last Thursday, under the auspices of the Royal Dublin Society. The show is decidedly the most successful which we have seen, either in Dublin or anywhere else, both as to the number of entries and the excellence of the specimens. Passing by the cereals and leguminous crops, which were very creditable, but which present few features worthy of notice, we come to the plants cultivated for their roots and tubers. Judge Radcliffe (per his steward, Mr. Lincham), and Mr. Vernon, of Clontarff Castle (steward, Mr. Bowers), are at once the most extensive and successful exhibiters in this department. The forms had 109 entries, all admirable specimens. Some of the mangels are on average half a stone heavier than any yet produced. In the long red, red globe, and yellow globe varieties, Mr. Vernon got first prize. We apprehend Mr. Lencham's were weightier specimens, but Mr. Bower's were cleaner and better grown. These gentlemen exhibited sugar beet nearly as large as the largest of the mangels; and if the specimens of Robert Rabi can at all be considered a fair exponent of what that root is capable of producing, the farmer may safely calculate on having another valuable crop for feeding cattle. We have experimented largely on this root, and our opinion of it is certainly very favourable. It is a hardy and nutritious crop. At first the yield was so inferior that many abandoned it immediately; but they seem to overlook that on its first introduction the yield of the turnip was equally small.

We may be excused for undertaking to correct an opinion which, from judging by the monster root at this show, many persons, especially landlords, form as to the capabilities of the soil. One often hears the question, "Why can't my stewards and my tenants grow as large roots as these? My steward raises only 25 or 30 tons an acre, and here I find as much as 60 or 80 tons. Had my land been skilfully farmed, my rental would be double what it is!" These are questions of vital interest to the agricultural community. And with all deference to the exhibiters we have named, we must express the opinion that the specimens exhibited on this occasion have not been produced by legitimate means. We don't mean to detract from the merit of these exhibiters; they have all the same means of *forcing*, and the same command of manure and labour; but the weak point in the whole system is, that only a few roots are taken as the standard of superior skill and well-directed industry. Mr. Lencham is, beyond all doubt, a most successful farmer, and so is Mr. Bowers; but give either of them an ordinary farm, and no extraordinary means, and will he produce mangel weighing 2½ stones?

We would next draw attention to the potatoes. As usual, Dr. Taylor is an extensive and successful exhibiter of this tuber. "Taylor's seedlings" were justly awarded a first time. Several excellent varieties were contributed. We find that great confusion has arisen respecting the White-rocks and Downs, which are generally regarded as the same potato; they were so regarded on this occasion. They possess distinct properties. The White-rock has a pink blossom, with a slight pinkish tint in the eye; high in the shoulder, and hence the term "rocky." The Down has a white blossom, a soft and *downy* eye, not so coarse a potato as the Rock, and occasional specks are seen under the cuticle.

We were glad to see that the agriculturists in connexion with the National Board of Education have cheerfully come forward for the first time as exhibiters of farm produce. This is a step in the right direction. Much has been said against the Board school farms of late; and the most judicious course which the agriculturists could pursue, is to come fairly before the agricultural public, who are competent to judge for themselves, and who can see if the managers of these institutions are up and stirring. As we cannot here enter into their merits, we will only observe that the collections contributed,—but not for competition, a wise idea, as public bodies and private individuals should not compete,—are exceedingly creditable in quantity and quality.

A VISIT TO THE SMITHFIELD CLUB FAT CATTLE SHOW.

SIR,—The season has again come round at which the agricultural gatherings are directed to the Smithfield Club Cattle Show in Baker-street; and a cab being scarce, and an omnibus generally *non est inventus* yesterday, on account of the dense fog, I groped my way thither by the "marrowbone stage," as they say—the only resource left to me; a dangerous alternative for old bones like mine to be reduced to. I arrived, however, safe and sound, and was pleased to find that the discomforts of the weather had not prevented the public from turning out on the occasion, but that the attendance was as numerous as ever; a plain proof that, unlike our neighbours the Parisians, the Londoners take a deep interest in these exhibitions.

Any Englishman, indeed, who has the real welfare of his country at heart, and is more fond of the *solid* in national glory than of the *superficial*, may well feel proud of the magnificent display of animals exhibited this year. I saw also many foreign gentlemen there, but did not recognize so many as I could have wished. The subject of agriculture is viewed in a different light on the continent from what it is with us. Even in France, where powerful efforts have been made by the government to drill the higher class of the landed interest into a liking to it, the success hitherto has been very partial and weak. Nor will it be possible to effect any great and important change in this respect whilst the subdivision of the land into minute portions continues. This is the great bane of agriculture, not only because small occupiers, such as the overwhelming majority of French farmers consists of, have neither the skill, the disposition, nor the capital to carry out improvements, but because the very circumstance of the land being in the hands of such a class of cultivators excites disgust of rural affairs amongst those classes which in England are the chief supporters of agricultural institutions. This, however' is a digression for which I must apologize.

I have termed the display of animals a magnificent one, and such it certainly is. I think the show of cattle far superior to that of last year, and I'll tell you why; simply because the graziers have taken the hints that have been given them from time to time, and have attended more to symmetry and compactness of form in the selection of their cattle, than to that excessive obesity which has characterized the former exhibition, and which led a tallow-chandler to remark, in an excusable pun, "It was much more advantageous to the *lights* than to the *liver*."

The show of Devons is an admirable one: they are perhaps *smaller* this year, generally speaking, than last; but in this respect the standing toast of the late Earl of Leicester, "*small in size but great in value*," has been adopted by the graziers. Some of this breed show a perfection of symmetry never exceeded. Amongst these I noticed No. 6, which received the first prize in class 1, and No. 11 in class 2, which I think was more entitled to the first prize of £25 than that of £10, which it received. Mr. Heath has certainly been very successful this year, and has contributed some excellent types of other breeds as well as of the Devons.

The heifers and cows of this latter breed were admirable. Nos. 23 and 24 were everything that can be desired in point of symmetry and compactness. The latter number, which took the first prize, is certainly the most finished, but I question whether No. 23 would not equal, if not excel it at the same age. No. 30 also is a complete animal, and does equal credit to the breeder and the grazier.

Amongst the Herefords and Shorthorns I noticed some first-rate animals, but cannot stop to particularize all of them. I found I had put a mark to several which had not received the special approbation of the Judges, amongst which were No. 72, remarkable for the degree of *finish* it has attained at the "tender age" of two years and eleven months; No. 80, which does not appear to have even been "commended"; and No. 173, an extra shorthorn heifer, which I think is as compact an animal as any in the show, although not specially noticed. The other breeds possess less interest with me, but there are some very fine cattle amongst them, particularly the "Sussex breed." Are these a distinctive race of cattle, or a mixed breed adopted by the Sussex farmers at some by-gone period? Their history is worth inquiring into, and if any of your Sussex correspondents can throw light upon it, their doing so will confer a favour on the public generally, everything connected with such a subject being interesting and important to the agriculturist.

I was surprised to see so few Galloway or Aberdeen Scots, and should regret to find that that breed is less in favour than formerly. They have stood the test of time in my native county, and have always proved the most profitable of any cattle for either winter or summer grazing; whilst no beef is superior to theirs on the table. With the Irish breed we can very well dispense; their long horns and pugnacious tempers rendering them dangerous to other cattle, either in the pasture-field or the yard. The Highland Scots are equally objectionable on the same account, and never ought to be put with other cattle. Small as they are, they will drive a shorthorn of giant size, compared with themselves, out of any yard.

Upon passing cursorily through the sheep-pens the first time, it struck me that that department was less satisfactory than it was last year. A second and closer inspection convinced me that this is the case *only* with the Southdowns, which certainly are neither so numerous nor so generally meritorious as they were last year. Two or three of the breeders, however, of that race have maintained their standing; and amongst them are Mr. Rigden and Lord Walsingham. I do not think the Judges have done the latter noble breeder justice in awarding him only the second prize for No. 267 (Class 37), for I certainly consider them a superior pen of sheep to No. 269, which obtained it; and I know that this opinion was shared by others. The Duke of Richmond has some excellent pens of Southdowns, and carried off a full complement of the honours of the Show.

Some of the Hampshire and West Country Downs are remarkably handsome sheep. Amongst these I particularly noticed 274, 279, and 280, as possessing extraordinary merits, although neither of them obtained a prize, and only one of them (280) was even commended.

Of the long-woolled breeds there are some excellent specimens. No. 181 is what the French would call "magnifique," and well deserved the distinction of the first prize and silver medal. Lord Berners' *pure* Leicester (No. 191) very properly won a "golden opinion" in addition to the £20 prize. Mr. Overman's half-bred Down and Leicesters were an excellent type of that breed. I regretted not seeing the name of his relative, Mr. Henry Overman, of Weasenham, amongst the exhibitors this year.

My remarks on the "swinish multitude" must be brief. In one word, they come fully up to the mark of

last year, and I must again express my astonishment at the enormous weight most of the pigs have attained in an incredibly short period. One pen of these animals, only five months and a few days old, were estimated by two butchers to weigh 12 *stone long weight*, each. This is making good use of their time with a vengeance. The pigs-royal were not so successful as last year, but I can assure the royal breeder and feeder that this was from no fault in the stock, which is as lovely as ever; and we are sure his royal highness will feel more pleasure in witnessing the perfect impartiality of the Judges than he would have done in receiving the first prizes.

I noticed one *improvement*, which appeared to me somewhat too refined. Several of the pens were furnished with *pillows* for the pigs to lay their snouts on when they were sleeping. What would the Highland chief of the last century (mentioned by Walter Scott), who kicked a snow-ball from under his son's head, calling him "an effeminate young rascal, not to be able to sleep without a pillow"—what, I repeat, would the old chieftain say to pigs being furnished with such luxuries?

I must reserve my observations on the machinery, &c. Yours, &c.,

AN OLD NORFOLK FARMER.

London, Dec. 9.

PLATE II.

TWO LABOURERS' COTTAGES,

ON THE ESTATE OF SIR GEORGE N. BROKE, BART., C.B., AT BROKE HALL, NEAR IPSWICH, SUFFOLK.

Upon the present Baronet succeeding to the picturesque property of the Broke family, running for some distance along the south side of the Orwell, one of the prettiest rivers in England, he determined to effect considerable improvements in the dwellings of the farm servants and other peasantry on his estate. In furtherance of this object, he has erected, on various parts, model cottages, according to the accompanying view and plan.

These are constructed of red brick, relieved with black, worked in different patterns. The roofs are of high pitch, and covered with plain tiles, the best and most durable covering that has yet been discovered, effectually excluding from the upper rooms heat in the summer and cold in the winter.

The cottages have an abundant supply of water from a well sunk at the back of each pair, in addition to as much soft water as can be caught from the roofs. They are also thoroughly well drained.

The two front rooms on the ground-floor are of wood; the others have pavements and bricks laid on a good thick bed of concrete. None of the wood work is painted, but merely slightly stained and varnished, by which process the grain of the real wood is preserved, and the material itself sufficiently protected.

The height of the lower rooms is eight feet three inches, and the chambers (of which there are three to each cottage) six feet nine inches to the springing of the roof, and ten feet nine inches to the collar, to which they are ceiled. Every bedroom has a fireplace and stove.

Each cottage is provided with a good-sized baking oven, copper, sink, and well fitted up pantry, besides the requisite outbuildings for wood, coals, and other conveniences.

The glazing of the windows is done with quarry lead lights, in iron frames and casements.

The cost of each pair of cottages has averaged about £300, and the occupiers seem greatly to appreciate the boon that has been thus conferred on them.

A good-sized piece of garden ground has been allotted to each, fenced off with low wood fencing.

The cottages have been erected from the designs of Messrs. Morgan and Phipson, architects.

CALENDAR OF AGRICULTURE.

This month is often very stormy, especially in northern latitudes, where snows and frosts prevail. In hard weather, carting will form the chief attention of the farmer—stones to drains and roads, fuel to the dwelling-houses of the farm, and of dung from the cattle-yards to the fields, where it will be wanted for the fallow crops. Lay the heap in a lane, or in a convenient place in the field; make it oblong square in shape, sloping at the ends to allow the loaded carts to pass upon and over it; spread each load evenly over the heap of six feet in height, dress it neatly, and lay earth on the edges. The heap should have a dry lair and level.

The ploughing of lands for Lent crops will be forwarded in fresh weather, and very advantageously during this month, as a time is given before sowing for effecting a pulverization, and it does not, by a lengthened exposure of the land, reduce it into a hard and battened condition. The ploughing of leys for grain crops, and of stubbles for fallows, must be vigorously pushed in this month.

In fresh weather, continue the cutting of copses and underwood, the cutting and splashing of hedges, the scouring of ditches and road sides, and clear water-courses; cut drains to half the depth to be finished in summer. Float water-meadows, and lay dry occasionally. Sow winter and spring wheats on lands cleaned of turnips, and on fallows left in autumn.

Collect and prepare artificial manures of every kind, and keep them under a dry, open shed.

The live stock on the farm of all kinds will require the most constant and unremitting attention of the farmer, if he would rear the animals to profit, and derive advantage from his labours, never forgetting the great effects of minute care in increasing the produce of a farm. Supply the cattle in the yards and horses with fresh straw daily, and give turnips or other roots early in the morning, that the animals may eat during daylight, and be seen when choked or swollen. Turnips are better fresh drawn from the field daily as wanted; but the danger of heavy snows covering the roots from use, renders necessary a heap at the homestead, containing a few weeks' supply. The yards must be littered with straw frequently—thinly and evenly.

The milch cows will now begin to drop calves; feed with succulent food, with steamed roots and chaff. Suckle both veal calves and for weaning; disregard the old maxim that animals must be starved in order to be reared at little cost; when milk is exposed, the most valuable parts—the gaseous fluids—go off by evaporation; hence the superiority of suckling over hand-feeding. When dairy produce is wanting, use a part of the cows for that purpose, and the other for rearing calves; allow ample food in every case. Have the calf pens divided into single apartments, about four feet by eight feet, opening into the cow-shed from the end or from behind, if the width of the shed admit.

The sheep flocks must have fresh turnips daily from the field, rooted, but not topped in the separate fields where the animals are lodged in different flocks, as ewes, store flocks, and fattening flocks, as arranged after autumn. The lambs of the last year and the feeding flocks may be confined on the growing turnips, or be fed on a ley or stubble field. A two-horse cart load will be sufficient for forty fattening sheep, and to keep one hundred in store condition.

Feed farm-horses with cut chaffs of clover and straw, oats and beans, and give a warm meal of steamed potatoes in the twilight, after the day's work is over.

The piggery must not be neglected; feed largely and litter amply. Rear the store pigs with roots; as potatoes and beet, raw; the fattening hogs with steamed roots, chopped and mixed with meals, served regularly thrice a day. No stock repays attention better than pigs.

Last in common estimation, but not least in general use, comes the poultry yard. Feed with light grains and steamed potatoes, mashed and mixed with meals, in a shed under cover, and have the lodging-house comfortably fitted up, and heated, if possible. Separate apartments for each kind of animals must be provided.

AGRICULTURAL REPORTS.

GENERAL AGRICULTURAL REPORT FOR DECEMBER.

Notwithstanding that only moderate supplies of home-grown wheat have been on sale in the whole of our leading markets, and that the imports from abroad have not been to say extensive, the wheat trade has continued in a most inactive state, and prices have given way to some extent. In many quarters it has become a question for serious consideration whether we have yet reached the lowest point; but we are not prepared to agree with some parties that ruin is staring the agricultural body in the face, because the causes which have led to the rapid decline in the value of produce are exceptional, and may eventually be removed. In the first place we must bear in mind that we have been passing through a commercial crisis of a most severe character; in the next, that the consumption of the better kinds of food has, as a consequence, fallen off; in the next, that the value of money has ruled unusually high; and, lastly, that the French Government have allowed the export of native produce free of duty. Without assuming that we shall have any great increase in the use of bread during the next two or three months, we may safely state that the worst of the commercial panic has passed away, and that, as stocks of manufactured goods are now becoming small in nearly all the markets of the world, we shall shortly have a return of that prosperity which, up to a certain point, was taken as a true index of our commercial greatness. Money, too, is now becoming more abundant, and discount accommodation can be obtained on much lower terms. There are indications of a steady upward movement in the value of wheat; but then we may have to contend with large importations of flour from France, and, if the supplies fall into comparatively weak hands, continued sales may be effected to the prejudice of the value of home-manufactured qualities. The prospect of large arrivals of this article alone keeps the wheat trade in a state of depression, because we see no reason whatever to assume that we shall receive other than limited quantities from the United States during the whole of the winter, and because future supplies of foreign wheat—especially from the North of Europe, owing to the closing of the navigation—will be on a very limited scale during that period. Again, owing to an unusually large number of forced sales, the stocks of foreign wheat in the United Kingdom are now reduced to a narrow compass; but, against this deficiency we must place an unusually large crop of English, the bulk of which is still in the hands of the growers, and the imposition of a duty of 20s. for every twenty-two gallons of spirit imported into France. This duty will of necessity check the demand for barley in this country for distilling purposes, and throw the greater portion of the foreign supply into the hands of the third-class millers, who are now competing with the first-class on severe terms. But even these adverse influences may be counteracted by the partial failure of the potato crop, which for some time past has been partly made good by extensive arrivals from France and other parts of the Continent. Supplies from those quarters, however, cannot be continued at their present rate, or about 1,500 tons weekly, and we may eventually be thrown more upon our own resources than appears to be generally imagined. For the reasons here alluded to, we see no reason to apprehend a further rapid decline in the value of wheat or other articles.

For the time of year, the weather has been remarkably fine and open, and the wheats have, consequently, stood in need of frost to check premature exuberance. They are certainly looking well; but, unquestionably, they are more forward than is desirable. Out-door operations generally are in a satisfactory state in all parts of the country.

We regret to find that the potato pits exhibit unmistakable signs of extensive disease. The quantity of potatoes lost this year by rot is immense; hence, good and fine samples are now commanding in the metropolitan markets from 100s. to 140s. per ton, and these high quotations have produced an enormous importation of potatoes from the continent. The arrival during the month has exceeded 5 000 tons, chiefly of a third-rate quality, though free fr m disease, and which have sold at from 55s. to 65s. per ton. There is still a large supply in France and Belgium, but it is a debatable ground whether future imports will keep up to their present amount.

Prices of both wheat and flour rule very low in France, notwithstanding that flour has been shipped to some extent; and they continue to exhibit a fair margin of profit on exports to this country. In nearly all the other markets of the world, the result of abundant supplies of produce, the quotations are comparatively easy.

The various cattle markets have been well supplied with beasts in first-rate condition for Christmas consumption. The trade, considering the extent of the supplies, has been tolerably healthy, and prices have ruled moderately high. Other kinds of stock, except pigs, have sold at very full quotations. As regards the rather low value of pigs, we may observe that their supplies have wonderfully increased in this country in the course of the year, and that, consequently, the demand for them has been more readily met.

The wool trade has continued in a state of great depression. Prices of all kinds of wool have fallen to a serious

extent, arising from the commercial panic, and up to the present time there are no buyers unless at further depressed currencies. The American dealers have returned to this country nearly 9,000 bales, originally shipped, but which are now being forced for sale here.

For hops there has been only a moderate demand. The supply in the hands of the growers and factors continues large, and prices have consequently ruled very easy. About 900 bales have come in from Hamburg; but, owing to the high duty, they have not entered into competition with native-grown qualities.

In Ireland and Scotland the transactions in wheat and other kinds of grain have been on a very moderate scale, and prices have had a drooping tendency. The shipments to England have been on a very moderate scale.

REVIEW OF THE CATTLE TRADE DURING THE PAST MONTH.

Notwithstanding that the total *number* of beasts exhibited in the Great Metropolitan Market for Christmas consumption has fallen short of the corresponding month in 1856, the supply, taken as a whole, has seldom or never been equalled in weight, quality, or symmetry. Taking advantage of past experience, the breeders and graziers have persevered until they have succeeded in effecting an important and most gratifying change in the symmetry of the various breeds; consequently, they have at length blended fat and lean together, and altogether repudiated the production of monstrosities, which, in a general way, leave very little profit either to sellers or buyers. Such a system as the present, if persevered in, must work immense advantages to all parties, and better regulate the judgment of those connected with the production of fat stock. All who visited the Show-yard in Baker-street, and who paid a visit to the "great" market, will perfectly understand the object of these remarks; they will understand that *fat alone* is not a feature which will ever render meat more valuable in the eyes of the consumer, or adequately repay either the breeder or the butcher. A point, then, of no ordinary importance has been gained, and which may eventually be a source of considerable profit to the producers.

When we consider the great *weight* of meat brought forward, and the drawback to the demand inseparable from a great convulsion in mercantile affairs, the trade may be called healthy. The beasts have sold at what may be termed fair, but not extravagantly high rates, and a much larger number of them have changed hands at market rates than we were prepared for. Sheep have likewise met a good trade at improved quotations. The Norfolk season for beasts has now commenced, and that from Lincolnshire is just closing. The forthcoming supplies from the eastern districts are expected to come up to their usual average.

The following are the total supplies of stock exhibited in the Metropolitan market:—

Beasts	19,830	head.
Cows	375	,,
Sheep	69,132	,,
Calves	1,209	,,
Pigs	1,915	,,

COMPARISON OF SUPPLIES.

Dec.	Beasts.	Cows.	Sheep.	Calves.	Pigs.
1856....	23,995	475	73,200	1,526	2,330
1855....	22,412	590	94,030	1,376	3,184
1854....	20,298	120	88,880	1,573	2,746
1853....	23,314	484	88,480	1,143	2,403

Beef has sold at from 3s. to 5s.; mutton, 3s. 2d. to 5s. 6d.; veal, 3s. 10d. to 5s. 6d.; and pork, 3s. 6d. to 5s. 4d. per 8 lbs., to sink the offal.

COMPARISON OF PRICES.

	Dec., 1856.		Dec., 1855.		Dec., 1854.	
	s. d.	s. d.	s. d.	s. d.	s. d.	s. d.
Beef, from	3 10 to 5	0.. 3	4 to 5	4.. 3	4 to 5	4
Mutton ..	4 0 — 5	6.. 3	4 — 5	0.. 3	6 — 5	4
Veal	3 8 — 5	6.. 3	10 — 6	0.. 4	0 — 5	8
Pork	3 8 — 5	4.. 3	6 — 5	0.. 3	2 — 4	8

Very limited supplies of foreign stock have arrived in the port of London, the total import being as follows:—

Beasts	931	head.
Sheep	5,133	,,
Calves	439	,,
Total	6,608	head.

In the corresponding month last year, we received 11,079; in 1855, 19,515; in 1854, 18,349; in 1853, 21,918; and in 1852, 11,870 head. It will, therefore, be seen that our importations from the continent are still falling off, and that consumption is almost wholly met by home produce.

The month's supplies from Lincolnshire, Leicestershire, and Northamptonshire have amounted to 10,100 shorthorns; from Norfolk, 2,200 Scots and shorthorns; from other parts of England, 4,500 of various breeds; from Scotland, 1,150 Scots; and from Ireland, 636 oxen.

Very large supplies of meat have been disposed of in Newgate and Leadenhall. Beef has sold at from 3s. to 4s. 8d., mutton 3s. 2d. to 4s. 8d., veal 3s. 8d. to 5s., and pork 3s. 6d. to 5s. 4d. per 8lbs. by the carcase.

Throughout the continent, fat stock continues very high in price—too high, indeed, to allow of profitable shipments to this country.

There has been only a moderate business doing in cakes and linseed, and prices have had a drooping tendency, although the imports have been on a very moderate scale.

SOUTH LINCOLNSHIRE.

In the midst of the serious depression under which agriculture is now labouring, it is very encouraging to witness such a beautiful season as this we are now so pleasantly passing through. We find ourselves engaged in such unusual farm-operations as to lead us to think that the winter has actually passed away, and the interesting routine of spring-culture in reality set in. We find in all directions the fallowing and clearing of land general; the cultivator, harrow, and roller everywhere at work, and the twitch-fires as numerous and bright as at Midsummer. This early preparation of the land for the spring-crops augurs well. Potatoes, should the season be favourable, may be planted just when the planter pleases; and the grain-crops have not been forgotten; many lands have been under preparation for them. This has caused abundant employment; and yet the labourer has not felt the reverse of the times, and, as much under-draining is in progress, we trust their services will be in constant requisition. Just one word on this point. I have read the report of the discussion on subsoil drainage at the Farmer's Club. It is one of the best and most practically useful they have yet entertained. Had some one touched upon dead-level drainage, I should have been better pleased. This is the character of this extensive county, and subsoil-drainage is by no means its leading department of business, and, in many parts of it, not practised. I think the occupiers, however, who neglect such subsoil-drainage, are in great error; and the result of the late discussion confirms this idea. For the most part, the whole district possesses a porous subsoil, and an equally open surface-soil. To subsoil-drain this soil is comparatively inexpensive. The water will drain laterally a long way, and the drains may be shallow—say 2½ feet, and the material thorns on arable, and wedge on grass-lands. I have drained considerably on such soils, and I fearlessly assert that a large proportion of South Lincolnshire may be effectually subsoil-drained at a cost of from 20s. to 30s. per acre: who, then, would neglect subsoil-drainage? But to my report. The grass-lands look like May-pastures, and the stock doing well. Turnips and coleseed hold out fairly, but do not possess any fattening quality, and the sheep progress very slowly. We have abundance of keeping at present. What a retrograde state we are all in! wheat thirty per cent. lower than the highest point since harvest, and other grain nearly as bad! Wool is thirty-five per cent. below its highest point. Store stock of all kinds have gone down in similar proportion. Fat stock still bears a good price, but looks downwards; notwithstanding, we are strongly inclined to believe we have seen the worst. The potato-crop is wofully bad, so no great amount of food can be derived from it. Bread must be the great support, and, as farmers have almost ceased thrashing for the present, the supplies must run short. Fat stock are scarce

except porkets. Upon the whole, we do not despond; but as things become a little more settled, we look for a reasonable advance in all farm-produce, and trust that the new-year will be one of the most satisfactory we have known, for this reason—the abundant yield can be afforded at a moderate price; so that the consumer and producer are alike benefited.

WEST GLOUCESTERSHIRE.

The continuance of mild weather since the last report affords but little for comment upon that subject. There has been an increased quantity of rain during the last ten days, but every operation is in such a state of forwardness that no interruption or inconvenience is experienced. The wheat is looking beautiful, perchance too luxuriant; and a check to its vegetating progress will come opportunely, providing it does not occur when the spring is far advanced. Frost would now prove seasonable and acceptable to the land and the stock; for although there are not at present complaints worth notice, the health of animals would be promoted by a more bracing atmosphere. The verdant state of the pastures offers temptations to keeping cattle in the fields, yet the homesteads are far more suitable to their healthy condition. The cold state of the grass at this season of the year, saturated with wet, is not conducive to condition—a most important consideration. This is one of the weakest points in the management of many of the dairy farms in this district. It is too much the custom to keep the stock upon grass as long as there is any for them, with a view to the saving of the hayricks; if it keeps them alive, little respect is paid to their future state, and great loss is sustained in the spring, the early production of cheese runs short, and the middle of summer arrives before the cows supply that abundance and quality of milk that are essential to profit. Nor is it the cows of mature age only that suffer by such treatment; the young stock become emaciated during the winter, contracting too diseases which are oftentimes incurable. It is very gratifying to observe that the potatoes have not gone off in the store-pits to anything like the extent complained of in many parts of the kingdom; this, it may be mentioned, is not an extensive potato growing county—there are few cultivated beyond the requirements of the grower. As yet, no preventive that can be depended upon has been discovered as an antidote to the disease; but the best results appear to be attendant upon the following practice: To work the ground intended to be planted with potatoes in the autumn, or at the latest in October or November, and at the same time apply the manure. Prepare a compost of lime and soil, or lime and vegetable refuse; when the proper season arrives for planting the potatoes, furrows are opened to receive them, and a moderate portion of the compost scattered in the furrows, which are afterwards filled up with the ordinary soil. This method appears to be more successful than using fresh lime. Farm-yard manure placed in the furrows where the potatoes are planted, or artificial manures of any kind, are exceedingly prejudicial. The very early planting of potatoes has been adopted by way of experiment as a preventive of the disease with questionable success; it produces a precocious faculty, which interferes with the important property of keeping. Potatoes planted in February or March will evidently arrive at maturity earlier than those which are planted in April or May. They will consequently send forth their shoots the following spring, at a time conformable with their maturity; and at this period there are many of the early-planted potatoes of last year which have sent forth shoots several inches in length. Continuing to plant them early year after year evidently creates constitutional precocity. The apples appear this year to have caught an infection similar to the potato disease; great complaints are made of their rotting extensively and rapidly in the heaps, before they were made into cyder. This will most probably have an injurious effect upon the beverage; indeed, there is a good deal of it that already tastes tainted. Every succeeding year produces improvements in the exhibitions of fat stock, whether it be at the emporium of hardware, the great metropolis, or in the provincials—so say the reports, and there is no cause to impugn the veracity of them. The splendid shows of Christmas fare fully confirm the high encomiums which have been awarded to the living exhibitions. Adopting the old saw "that the proof of the pudding is in the eating," we will leave those to award the final judgment who are more deeply skilled in gastronomic excellences after the culinary art has been displayed; and hoping that all our friends have enjoyed their Christmas dinners with the fullest measure of epicurean satisfaction, that they will award to the farmer the just meed of praise for his toils, his troubles, and his anxieties. This, upon the whole, has been a prosperous term, for which the agriculturists ought to be truly grateful; and in wishing them a happy new year, we will express a fervent hope that it will be as propitious, or more so, than the past.

AGRICULTURAL INTELLIGENCE, FAIRS, &c.

BANBURY FAIR.—It was not quite so full as we have seen. However, the quality of the cattle on sale was of the first character. Mr. Brickwell, of Overthorpe, exhibited a splendid ox, which was very generally admired. There was a moderate demand, the average price obtained being about 4s. 4d., although prime beef sold as high as 5s. per 8lbs. Mr. Caless sold by auction, in the fair, four prime Hereford oxen, and one three-year-old heifer, from his own stock, at an average of 35*l.* each. The supply of mutton, though not great, was equal to the demand, and sold from 4s. 4d. to 4s. 8d. per 8lbs. Fat hogs sold from 8s. 9d. to 9s. 3d. per score. There were but few good horses on sale.

BEDALE FORTNIGHT FAIR.—We had a good show of stock, which sold at reduced rates, and a portion unsold. Mutton sheep were well sold. Lean stock and in-calving cows were inquired for, but could not reach the figures they had been accustomed to do, having gone down from 10 to 12 per cent. Beef, 6s. to 7s. per stone; mutton, 5½d. to 6½d. per lb.

LEDBURY FAIR—Was very scantily supplied with all kinds of stock, excepting store pigs, of which there was a good supply. Sales ruled rather dull. Pigs did not realize so much money as at former fairs. Fat cows might be quoted from 6½d. to 7d. per lb.; sheep, 6½d. per lb.

PENRITH FORTNIGHTLY MARKET.—There was a very heavy supply of fat. Prices were down. Sheep fell as much as 4s. or 5s. a-head, and cattle, of which there was a moderate show, were down 2s. or 3s. per stone.

PRESTEIGN FAIR was well supplied with stock of all descriptions. Prime fat cows realized 6d. to 6½d. Lean stock was a drug in the market. Fat pigs may be quoted at 4s. 9d. to 5s. per 12lbs. Small and store pigs about half the price they were twelve months ago. There was a good supply of fat sheep, but prices had a downward tendency.

SHIPSTON-ON-STOUR.—There was a numerous attendance of dealers, with a good supply of stock, both store and fat. Stores fetched low prices, and trade very dull. A number of Irish cattle exhibited for sale were driven away unsold. Beef realized from 6½d. to 7d., and mutton averaged the same price. A pretty brisk trade was done amongst fat stock. On the whole the fair was well attended, and a good deal of business transacted.

SHREWSBURY FORTNIGHTLY MARKET.—The show of stock was more than usually thin, with the exception of pigs, which were penned in large numbers. Beef ranged, according to quality, from 5½d. to 6½d. per lb. Fat calves, in some instances, made 6½d. per lb. Cows and calves, of which there were but few, sold readily. Lean stock met with little demand. Mutton realized from 6¾d. to 7½d. per lb., according to quality. Fat pigs fetched about 5d. per lb.; stores were nearly unsaleable, and much lower in price.

STRATFORD-ON-AVON FAIR.—There was a very good show of fat stock, and a large attendance of buyers; but owing to the high prices asked for beef, trade was very flat, and ultimately lower prices were submitted to, and this caused a clearance of all the beef, which was of first-rate quality. Of store cattle there were but few; of sheep about 800 penned, and these were chiefly sold. We may quote beef and mutton, best qualities, as not exceeding 7d. per lb.

YORK FORTNIGHTLY MARKET.—The supply of all descriptions of horned cattle and sheep was very limited, and the demand equally so; hence the slow sale for both beef and mutton, the former at from 6s. 6d. to 7s. 6d. per 14lbs., and the latter at 6d. to 6½d. per lb. The sale for calving and dairy cows, grazing beasts, and sheep has been exceedingly dull, at prices below former rates.

REVIEW OF THE CORN TRADE

DURING THE PAST MONTH.

The closing month of the year which has now passd away was remarkable in many respects. The season itself was more like a mild autumn than winter; the grass having continued its growth, as well as esculents, and the wheat plant having attained a vigour quite unusual. Of the earlier pieces, some have become rather winter-proud; and the almost entire absence of frost has encouraged the growth of vermin in some localities: but the weather not only being mild, but dry, the young wheat, as a whole, perhaps, never gave a better promise, while ploughing and all kinds of field work have been prosecuted with scarcely any interruption. Human labour has therefore done its best, and the future must be dependent on the Great Ruler of the times and seasons; but the present prospect is full of hope and encouragement.

The last Monday in November, being the 30th of the month, could not be included in the market statements; but it proved the only cheerful one that could be recorded, as the wheat trade then closed with an advance of 2s. per qr., reducing the month's decline to 2s., instead of 4s., as respected the London markets; but all, and more than all, the improvment was lost on the opening of December, prices then declining 3s. per qr., from which there has been no rally, though no further decline has since taken place. Before the last crop was gathered, stocks were running short; and the averages on the 20th July rose to 63s. 10d., the highest point attained through the year. After the gathering of harvest, when the yield both in this country and abroad was known to be abundant, they gradually declined to 53s. 11d. by the 9th of November; and the fall since then to 49s. 3d. on the last Monday in the year, which is 4s. 8d. per qr., may fairly be attributable to the permitted importation from France, coupled with the almost unexampled crisis in monetary affairs. As the year opened at 59s. 8d., the decline from its commencement to its close is 10s. 5d. per qr.; the lowest point reached being on the 14th of December, viz., 48s. 3d. As to the future, though unlooked-for events have hitherto frustrated all calculations. we cannot but expect a more cheerful state of things when the holidays are passed, and the new year has fairly opened. France, which was so dreaded, can no longer send in shipments either of flour or wheat without a serious loss; and farmers there, with liberty to export, seem no longer inclined to force off their produce. The Baltic may fairly be expected shortly to close by frost, as well as North America; and though heavy arrivals of foreign wheat have been pouring in from the East, sales involve great sacrifices, and prices of Ghirka wheat at Odessa and Berdianski are actually higher than on the London market, while the financial state of the country is rapidly improving; and the serious failure in the potato crop, not felt at present because of the anxiety of growers to quit their stores, and the present liberal foreign imports, must, as spring advances, greatly increase the consumption of wheat, the stocks of which, all over the world, were at the lowest ebb before the new gatherings. The following prices show the state of foreign markets: The best winter red wheat at New York was quoted 41s. to 43s. 6d. per qr. free on board, white to 51s. per qr. Odessa quoted 38s. to 47s. per qr. for Ghirka wheat; sales of the best being made, freight included, in London, at 46s. At Berdianski, prices of soft wheat ranged from 49s. 6d. to 51s. At Taganrog, which is stopped by frost, the quotations were to 37s. 8d. per qr. At Galatz, trade had become so prostrate that prices of wheat had fallen to 25s. for 59s. to 61lbs. per bushel quality. Freights were quoted 11s. per qr. Nothing can be expected thence till spring, when the relative lowness of prices may attract orders, and send them up. Shipments have been making from Danzic and Hambro' with all haste, in anticipation of the set-in of frost. Stocks in store were short; and as supplies arrived, they were placed from the craft on board ship, to save granary expenses. The best high-mixed at the former port was quoted to about 46s. per qr.; prices at the latter were to 44s. 6d. per qr. Stettin quotations were were about 41s. 6d. per qr The mean price of wheat in Belgium was 44s. 4d., fine red at Louvain being held at 45s. per qr. Dutch prices still ranged high, though markets were continually receding, Polish wheat at Amsterdam being still quoted 53s. 4d. The influence of French imports has been most considerable in Spain, where prices have again receded to a moderate scale, though it is expected that the country has not grown enough for its own consumption, notwithstanding some local abundance. At Valladolid wheat was quoted 45s per qr.; flour at Santander, for first quality Spanish having only brought about equal to 44s. 6d. per English sack. At Paris Wheat was quoted to about 43s. per qr., and Flour there to 32s. 6d. per English sack; but the expenses of transit, with duty on both sides and commission, stop consignments on the northern sea-board; where facilities exist to make shipments, the rates leave a loss. Nantes quotes 43s. for wheat, worth only 44s. in London; and wheat in Algiers was of the same value.

The first Monday commenced on the back of moderate supplies of wheat, with but a scanty show for the morning from Kent and Essex; but the weather having been very damp, the samples were much deteriorated in condition, and at the Essex stands fair runs were offered at a reduction of 3s. per qr., with but slow progress. The foreign trade was not equally affected; but to sell, rather less money had to be taken. In the country generally prices were not so shaken; but Bristol, Norwich, Spalding, and Newmarket were 2s. to 3s. per qr. lower, the general reduction being seldom more than 1s. per qr., and Portsmouth was firm. Liverpool on the first market yielded 3d. per 70 lbs.,

but did not further give way on Friday. London as the week advanced was further depressed, and on Friday appeared to reach the lowest point, the trade seeming quite unnerved, without any accumulation of supplies; but the monetary crisis was, perhaps, the cause of the then depression.

On the second Monday the low tone of the previous market had passed away, though the supplies were rather better, and the rates of the previous Monday were recovered for all really fine dry parcels, which were scarce, but those out of condition were about 2s. per qr. reduced. In foreign there was rather more doing, but somewhat lower prices were taken. The country trade again showed a better feeling than the metropolis: Birmingham, Hull, and Newark were 1s. higher, and Spalding was nearly 2s. improved; and the markets held on Saturday were mostly rather dearer; but Portsmouth, which had been an exception to most other places on the previous week, fell back to the common level. Liverpool advanced 3d. per 70 lbs. on Tuesday; and on Friday a further rise of 1d. to 2d. per 70 lbs. on fine quality took place.

The third Monday, with small supplies from the near counties, was a quiet day, in anticipation of Christmas, good-conditioned parcels being cleared at former rates, though those out of order were placed with difficulty. Foreign was firm. Christmas occurring on Friday, all the country towns partook of a holiday character; but at the markets held, there was scarcely any alteration in prices.

The last Monday was a repeat of its predecessor, there being but a slow steady trade, without any quotable variation either in English or foreign prices, none being anxious to increase stocks at the year's close.

The supplies of wheat for the four weeks of December were as follows: 17,269 qrs. English, and 59,068 qrs. foreign, the weekly average being 19,084 qrs., which is about 4,000 qrs. below November. The exports have been trifling, viz., 200 qrs. wheat, 100 brls. 125 sacks of flour; but the imports into the principal ports of Great Britain in the four weeks were liberal, viz., 429,562 qrs.; the arrivals of November into the United Kingdom were 456,804 qrs. wheat, and 267,159 cwts. flour.

The flour trade, as respects country sorts and foreign, has been in sympathy with wheat, the first Monday receding 1s. per sack, without any further reduction subsequently; Norfolks commencing at 34s., and closing at 33s. per sack; but town samples for first quality have continued unaltered at 47s. per sack. Foreign yielded on the second Monday, on a large supply from America, to the extent of 1s. per brl., the general quality of good western being about 28s. per brl., extra to 30s. per brl. French sold well on the first offers; but lately having left a loss, agents have not been able to sell free on board, and unless markets recede further in the northern ports, the trade must fall off. The imports into London during four weeks, in English sorts from the country, have been 73,578 sks. 31,409 brls. American, and 9,425 sks. principally from France, which has proved little more than half a week's supply from the country. The weekly arrivals have, however, exceeded those of November by 2,813 sks. and 5,203 brls., and the comparative firmness of prices seems rather indicative of an advance.

The barley trade all through the month has been very heavy, the comparative absence of demand for fine malting qualities exciting some surprise, but the slow sale of malt at somewhat reduced rates sufficiently accounts for the neglect, the pressure of the times having lessened the consumption of malt liquor; while the liberty given in France to use grain for distillation, as well as the duty imposed on foreign spirits, has made the inquiry for the medium descriptions very limited. The first Monday had the best supplies, and the market then gave way for all sorts 1s. to 2s. per qr.; the second Monday showed a still duller state of trade for secondary qualities, which sold more in buyers' favour. Towards the month's close, however, there was a rather better demand, with a tendency to improve. The arrivals into London for the four weeks were 17,880 qrs. English, and 59,859 qrs. foreign, which gives an increase over the previous month of about 8,000 qrs. weekly.

Malt has been dull all through December, without much change of value; but 1s. per qr. less was quoted on the second Monday.

The oat trade, with a falling off in the supplies to less than one-half of those in November, has not recovered from the effects of previous gluts, dealers then having liberally stocked themselves, and that without advantage, having felt no inducement at the end of the year to make fresh purchases, though they have had the opportunity to do so on still more moderate terms. The first Monday having a good supply, prices receded 6d. per qr., and though ever since then they have been exceedingly small, there has been no improvement in value; with, however, the certainty of the cessation of Russian supplies, of which the gluts have alone consisted, a deficient crop here, and a not over-abundant one abroad, and less grown in Ireland, we cannot help arriving at the conclusion that as the granaries here get relieved, markets will be rather dearer. The four last weeks show the following arrivals, viz: of English 1,648 qrs., of Scotch 4,365 qrs., of Irish 3,920 qrs., and of foreign only 74,020 qrs.; making the total weekly supply only 20,987 qrs., against 47,790 qrs. in November.

Beans have declined in the course of the month more seriously than other corn, the English supplies only being moderate; but the foreign were good, and as many are expected from Egypt there does not appear much prospect of a speedy improvement. Almost every market-day has noted some decline. The first Monday was lower 1s., the second 1s. to 2s., the third rather cheaper, and the last again 1s. per qr. down, leaving the top price of Mazagan about 34s., and fine small 40s. per qr. The imports for the month into London were 2,521 qrs. English, and 11,610 qrs. foreign, which being more than double that of the previous month partly accounts for the fall.

Peas have been heavy to sell, and about 1s. cheaper, the change taking place on the first Monday. The comparative scarcity of maples and duns keeps up prices relatively high, but boilers

being freely imported remain only on a par with hog-feed, the mildness of the season making the demand unusually small. Should a sharp frost come on, we may see these latter rally, as stocks are not heavy.

Linseed, though cheaper, has not declined at the rate noted in November. The first Monday having an unusual supply gave way 1s. to 2s. per qr., but arrivals since not exceeding an average, the prices have not further receded, though business finished slack. Foreign cakes were less in request, but the limited stock of English, and the preference given to this quality, have served to keep up their value. With the exception of canaryseed, which has given way about 5s. in the month, there has scarcely been any change in the value of seeds. Cloverseed has begun to arrive from America, Germany, and other parts, in moderate quantities, and some English samples have appeared; but though so near the season, buyers have kept entirely on the reserve, money being too scarce for speculative purposes, and the houses in France generally coming best off by realizing prices on their first sales, which have not paid here. English dealers this season appear to prefer a change. Prices in Paris now appear to have reached their lowest; and if business be deferred till the demand ensues, there may be a healthy and profitable trade. Mustardseed has continued at nominal rates. Rapeseed, hempseed, carraway, and coriander, have only been placed in retail at old prices.

POTATO MARKETS.

BOROUGH AND SPITALFIELDS.

LONDON, MONDAY, Dec. 28.—Very moderate supplies of home-grown Potatoes have come to hand since Monday; but the imports from abroad have been liberal, viz., 420 tons from Antwerp, 5 tons from Boulogne, 80 tons from Havre, 800 tons from Dunkirk, 517 tons from Rouen, 145 tons from Dieppe, 85 tons from Nieuport, 122 tons from Ostend, 4 tons from Hamburgh, and 5 tons from Rotterdam. The demand for all kinds is still very inactive, as follows:—

York Regents	140s. to 160s. per ton.
Kent & Essex do.	120s. to 140s. „
Scotch	80s. to 120s. „
Do. Cups	75s. to 85s. „
Middlings	50s. to 60s. „
Lincolns	80s. to 120s. „
Foreign	55s. to 65s. „

SOUTHWARK WATERSIDE, MONDAY, Dec. 28.—During the past week the arrivals both coastwise and from abroad have been limited, but quite equal to the demand. Trade is very dull, at the following quotations:—

Lincolnshire Regenta	60s. to 120s. per ton.
Perth, Forfar, and Fifeshire do.	90s. to 110s. „
Ditto ditto reds	60s. to 70s. „
French Whites	70s. to 80s. „
Irish do.	70s. to 80s. „
Belgian do.	60s. to 70s. „
Dutch Reds	80s. to 90s. „

COUNTRY POTATO MARKETS.—YORK, Dec. 19: Potatoes sell at 11d. to 1s. per peck, and 3s. to 3s. 4d. per bush.—LEEDS, Dec. 22: A fair supply of Potatoes, which sold at 14d. to 15d. per 21lbs. wholesale, and 15d. to 16d. retail.—MALTON, Dec. 19: A poor supply of inferior Potatoes sold at 12d. per peck.—THIRSK, Dec. 21; Potatoes 8d. per st.—RICHMOND, Dec. 19: Potatoes 4s. per bush.—MANCHESTER, Dec. 22: Potatoes 10s. to 15s. per 252lbs.

WOOL MARKETS.

ENGLISH WOOL MARKET.

LONDON, MONDAY, Dec. 28.—Although money haa become easier in the discount market, there is no disposition shown to purchase any kind of English wool. The supply of late has rather increased; but we do not anticipate any further reduction in prices, even though large quantities of colonial wool continue to be returned from the United States.

Per pack of 240lbs.

IMPORTANT TO FLOCKMASTERS.

THOMAS BIGG,

AGRICULTURAL AND VETERINARY CHEMIST,

BY APPOINTMENT, TO H.R.H. THE PRINCE CONSORT, K.G., &c.

LEICESTER HOUSE, GREAT DOVER-STREET, BOROUGH, LONDON,

Begs to call the attention of Farmers and Graziers to his valuable SHEEP-and LAMB DIPPING COMPOSITION, which requires no Boiling, and may be used with Warm or Cold Water, for effectually destroying the Tick Lice, and all other insects injurious to the Flock, preventing the alarming attacks of Fly and Shab, and cleansing and purifying the Skin, thereby greatly improving the Wool, both in quantity and quality, and highly contributing to the general health of the animal.

Prepared only by Thomas Bigg, Chemist, &c., at his Manufactory as above, and sold as follows, although any other quantity may be had, if required :—

4 lb. for	20	sheep,	price,	jar included	.....	£0	2	0
6 lb.	30	,,	,,	,,	.....	0	3	0
8 lb.	40	,,	,,	,,	.....	0	4	0
10 lb.	50	,,	,,	,,	.....	0	5	0
20 lb.	100	,,	,,	(cask and measure		0	10	0
30 lb.	150	,,	,,	included)		0	15	0
40 lb.	200	,,	,,	,,	.....	1	0	0
50 lb.	250	,,	,,	,,	.....	1	3	6
60 lb.	300	,,	,,	,,	.....	1	7	6
80 lb.	400	,,	,,	,,	.....	1	17	6
100 lb.	500	,,	,,	,,	.....	2	5	0

Should any Flockmaster prefer boiling the Composition, it will be equally effective.

He would also especially call attention to his SPECIFIC, or LOTION, for the SCAB, or SHAB, which will be found a certain remedy for eradicating that loathsome and ruinous disorder in Sheep, and which may be safely used in all climates, and at all seasons of the year, and to all descriptions of sheep, even ewes in lamb. Price 5s. per gallon—sufficient on an average for thirty Sheep (according to the virulence of the disease); also in wine quart bottles, 1s. 3d. each.

IMPORTANT TESTIMONIAL.

"Scoulton, near Hingham, Norfolk, April 16th, 1855.

'Dear Sir,—In answer to yours of the 4th inst, which would have been replied to before this had I been at home, I have much pleasure in bearing testimony to the efficacy of your invaluable 'Specific for the cure of Scab in Sheep.' The 600 Sheep were all dressed in August last with 84 gallons of the '*Non-Poisonous* Specific,' that was so highly recommended at the Lincoln Show, and by their own dresser, the best attention being paid to the flock by my shepherd after dressing according to instructions left; but notwithstanding the Scab continued getting worse. In December I informed the 'Agent for the above Specific,' that the flock was not cured, and that it required their immediate attention. The Agent informed me they should be at once seen to, but did not do so until *five* weeks afterwards, and in the mean time the Scab spread over the whole flock, that I never saw such a disgraceful sight in my life; and when the Dresser was sent over to inspect the Flock, he decided on not dressing them again, as one third of the Sheep had lost half their wool. I then agreed with an experienced dresser in Norfolk to dress the flock, and when he saw the sheep he declined doing them, as they were so very bad, and the time of lambing so near. Being determined to have the Scab cured if possible, I wrote to you for a supply of your Specific, which I received the following day; and although the weather was most severe in February during the dressing, your *Specific* proved itself an invaluable remedy, for in three weeks the Sheep were quite cured; and I am happy to say the young lambs are doing remarkably well at present. In conclusion, I believe it to be the safest and best remedy now in use.

"I remain, dear Sir, your obedient servant,

"For JOHN TINGEY, Esq,

"To Mr. Thomas Bigg." "R. RENNY.

In addition to the foregoing, he has very materially improved, as well as considerably reduced the price of his Dipping Apparatus; and he would venture to suggest that no Flockmasters ought now to be without one. Price in London.

CURTIS ON MANHOOD—SHILLING EDITION.

A MEDICAL ESSAY ON NERVOUS AND GENERATIVE DISEASES.

Just published, the 77th Thousand, with numerous plates, in a sealed envelope, price 1s., or sent, post-paid by the Author, for Fourteen stamps,

MANHOOD : The CAUSE and CURE of PREMATURE DECLINE, with Plain Directions for Perfect Restoration to Health and Vigour; being a Medical Review of the various Forms and modern treatment of Nervous Debility, Impotency, Loss of Mental and Physical Capacity, whether resulting from Youthful Abuse, the Follies of Maturity, the Effects of Climate or Infection; with Observations on a new and successful mode of detecting Spermatorrhœa, and other urethral discharges, by Microscopic Examination; to which are added, Curious and Interesting Cases, with the Author's Recipe of a Preventive Lotion.

By J. L. CURTIS, Surgeon, 15, Albemarle-street, Piccadilly, London.

At home for consultation daily, from 10 till 3, and 6 to 8. Sundays, from 10 to 1.

REVIEWS OF THE WORK.

"CURTIS ON MANHOOD.—Shilling Edition.—77th Thousand.—This is a truly valuable work, and should be in the hands of young and old. The professional reputation of the author, combined with his twenty years' experience as medical referee in the treatment of nervous debility, &c., fully accounts for the immense circulation which this popular and ably-written medical treatise has obtained."—*Sunday Times*, 23rd March, 1856.

"CURTIS ON MANHOOD.—The author has conferred a great boon by publishing this little work, in which is described the source of those diseases which produce decline in youth or more frequently premature old age."—*Daily Telegraph*, March 27, 1856.

CURTIS ON MANHOOD.—The book under review is one calculated to warn and instruct the erring without imparting one idea that can vitiate the mind not already tutored by the vices of which its treats."—*Naval and Military Gazette*, 1st Feb., 1851.

"We feel no hesitation in saying that there is no member of Society by whom the book will not be found useful—whether such person hold the relation of a parent, preceptor, or a clergyman.—*Sun*, Evening Paper.

Published by the AUTHOR; sold also *in sealed envelopes*, by GILBERT, 49, Paternoster-row; HANNAY, 63, Oxford-street; Mann, 39, Cornhill, London; ROBINSON, 11, Greenside-street, Edinburgh; HEYWOOD, Oldham-street, Manchester; HOWELL, 6, Church-street, Liverpool; FRANCE, 8, Side, Newcastle-on-Tyne; ASHLEY, Post-Office, Newbury; FERRIS & SCORE, Union-street, Bristol; PIERSON, Shrewsbury; JULT, Braintree; THEW, Lynn; PEAT, Chichester; LURCOCK, Maidstone; COOK, Ipswich; HUSCROFT, Bury St. Edmunds; DOVE, Swindon; JEAREY, Bridewell Alley, Norwich; SMITH, Cambridge; SLATTER, Oxford; and by all Booksellers and Chemists in the United Kingdom.

CHRISTMAS PRESENTS AND NEW YEAR'S GIFTS.

The exuberance of the feelings amid scenes of gaiety induces the fair and youthful to shine to advantage under the gaze of many friends, and therefore to devote increased attention to the duties of the Toilet. It is at this festive season that

ROWLANDS' AUXILIARIES OF HEALTH AND BEAUTY

are more than usually essential for preserving the Hair in its decorative charm, the Skin and Complexion transparent and blooming, and the Teeth in their pearl-like lustre.

The Patronage of Royalty throughout Europe, their general use by Rank and Fashion, and the universally-known efficacy of these articles give them a celebrity unparalleled, and render them peculiarly

ELEGANT AND SEASONABLE PRESENTS.

ROWLANDS' MACASSAR OIL

IS A DELIGHTFULLY FRAGRANT AND TRANSPARENT PREPARATION FOR THE HAIR, AND AS AN INVIGORATOR AND BEAUTIFIER BEYOND ALL PRECEDENT.

In dressing the Hair nothing can equal its effect, rendering it so admirably soft that it will lie in any direction, imparting a transcendent lustre, and sustaining it in decorative charm during the heated atmosphere of crowded assemblies.—Price 3s. 6d., 7s.; Family Bottles (equal to 4 small) 10s. 6d.; and double that size, 21s. per bottle.

ROWLANDS' KALYDOR

FOR THE SKIN AND COMPLEXION

IS UNEQUALLED FOR ITS RARE AND INESTIMABLE QUALITIES.
THE RADIANT BLOOM IT IMPARTS TO THE CHEEK,
THE SOFTNESS AND DELICACY WHICH IT INDUCES OF THE HANDS AND ARMS,

Its capability of soothing irritation, and removing cutaneous defects, discolorations, and all unsightly appearances render it

INDISPENSABLE TO EVERY TOILET.

Price 4s. 6d. and 8s. 6d. per bottle.

ROWLANDS' ODONTO,

OR PEARL DENTIFRICE,

Compounded of the choicest and most recherché ingredients of the ORIENTAL HERBAL, and of inestimable value in

PRESERVING AND BEAUTIFYING THE TEETH,

IMPARTING TO THEM A PEARL-LIKE WHITENESS,

STRENGTHENING THE GUMS,

AND IN RENDERING THE BREATH SWEET AND PURE.

Price 2s. 9d. per box.

CAUTION.—The name "ROWLANDS'" precedes that of the Article on the Wrapper or Label of each.

*** **Sold by A. ROWLAND & SONS, 20, Hatton Garden, London,**

THE

FARMER'S MAGAZINE,

AND

MONTHLY JOURNAL

OF

THE AGRICULTURAL INTEREST.

Dedicated

TO THE

FARMERS OF THE UNITED KINGDOM.

LONDON:
PUBLISHED BY ROGERSON AND TUXFORD, 246, STRAND.

PRICE TWO SHILLINGS.

ROGERSON AND TUXFORD,] [PRINTERS, 246, STRAND.

Patronized by the Principal Farmers and Graziers in the Kingdom.

CUFF'S FARMER'S FRIEND.

One dose of this invaluable medicine will cure the SCOUR or LOOSENESS in Lambs, Calves, Sheep, Colts, Heifers, Steers, and all Cattle, without leaving costiveness; and given occasionally to Beasts whilst fattening will promote a healthy and thriving condition. It will also perfectly cure the FRET, COLIC or GRIPES in Horses. Price 1s. 8d. or 3s. per Bottle.

CUFF'S FOOT-ROT POWDER

Is a cheap and effectual remedy for the FOOT-ROT or HALT, a single Packet of which will cure One Hundred Sheep, and large Flocks may be soon freed from the Disease by its use. It has been extensively used and highly approved of for nearly thirty years by large Sheep Breeders throughout the Kingdom. Price 1s. per Packet.

CUFF'S FLY, SCAB & MANGE OIL

Will very quickly destroy MAGGOTS in Sheep, and LICE or VERMIN in all animals. It will also cure the MANGE, and SKIN DISEASES in Horses or Cattle, and effectually cleanse a Flock of Sheep from the SCAB or SHAB. Price 1s. 8d. and 3s. per Bottle.

THE BRITISH SHEEP WASH

Is used for Dipping or Dressing Sheep and Lambs, without boiling, to prevent the Fly striking, and the Scab or Shab from spreading, and effectually to destroy TICKS, LICE, and VERMIN in Sheep. Price 2s. 9d., 5s., and 10s. per Jar; or 2s. 6d. per packet.

SHERWOOD'S ORIGINAL DRIFFIELD OILS

Are strongly and confidently recommended for preventing GANGRENE or MORTIFICATION after Lambing or Calving, and for Healing CUTS, STABS, WOUNDS, BRUISES, STRAINS, SWELLINGS, &c., &c.. As these Oils are in constant use by some of the most celebrated Breeders in the world, and have maintained a reputation about fifty years, it would be superfluous to enlarge upon their value and importance. Pints, 2s. 6d., Quarts, 5s.

Prepared by J. H. CUFF, No. 10, Smithfield Market, London, and sold by Druggists and Medicine Vendors

None is Genuine unless signed by J. H. CUFF in writing.

Under Royal Patronage.

PERFECT FREEDOM FROM COUGHS IN TEN MINUTES,

ASTHMA AND CONSUMPTION, COUGHS, COLDS,

AND ALL

Disorders of the Breath and Lungs.

ARE INSURED BY

DR. LOCOCK'S PULMONIC WAFERS

CURE OF ASTHMA AND COUGHS.

FROM MR. R. BAGLEY, BOOKSELLER, IRONMONGER STREET.

Gentlemen,—I have great pleasnre in communicating to you the beneficial effects many parties in and around Stamford have experienced from your excellent medicine, in asthma, coughs, and difficulty of breathing, and the manner in which they recommend them. One highly respectable gentleman in Stamford has experienced the most wonderful benefit in a severe and obstinate asthma, with which he has been troubled for the last twenty years. Calling at my shop the other day, he told me that he had a few days previously caught a bad cold, and by taking two or three Wafers on going to bed, he found the cough entirely removed the next day. I have sold dozens of boxes entirely through his recommendation. I have pleasure in adding that the gentleman is willing to give all the information possible to parties who may be suffering from the same disease, and on application to me I may give his name. I remain, gentlemen, your obedient servant, R. BAGLEY.

The particulars of many hundreds of Cures may be had from every Agent throughout the Kingdom.

To Singers and Public Speakers they are invaluable, as in a few hours they remove all hoarseness, and wonderfully increase the power and flexibility of the voice.

They have a pleasant taste. Price 1s. 1½d., 2s. 9d., and 11s. per box. Sold by all Medicine Vendors.

DR. LOCOCK'S COSMETIC.

A delightfully fragrant preparation, for improving and beautifying the complexion, rendering the Skin clear, soft, and transparent, removing all **Eruptions, Freckles, Sunburn, Tan, Pimples, and Roughness—curing Gnat Bites, and the Stings of Insects.**

In the process of shaving it allays all smarting, and renders the skin soft and smooth.

Sold in Bottles at 1s. 1½d., 2s. 9d., and 4s. 6d. each. Beware of Counterfeits. Observe the name in the Government Stamp *outside* the Wrapper. Sold by all Chemists and Medicine Vendors.

THORLEY'S FOOD FOR CATTLE,

AS USED IN HER MAJESTY'S STABLES,

And also on His Royal Highness the Prince Consort's Farm, Windsor.

FED ON THORLEY'S FOOD FOR CATTLE.

The property of His Royal Highness the PRINCE CONSORT.

The above are a few of the many Prizes obtained through the use of this invaluable Compound, which is adapted for all kinds of Stock, and now in use throughout the world.

Sold in Cases, containing 448 Packages—each Package one feed—at the cost of 56s. per Case; also in Casks, containing 448 feeds, with measure included, price 50s. per Cask. Carriage paid to any Railway Station in the United Kingdom.

None are genuine without the Signature being affixed to each Package or Feed.

Joseph Thorley

INVENTOR AND SOLE PROPRIETOR.

A

Central Depot.—77, NEWGATE STREET, LONDON.

PRICE ONE SHILLING EACH,

Neatly printed in foolscap 8vo., each Volume containing from 130 to 160 pages of Letterpress, with numerous illustrative Engravings,

RICHARDSON'S RURAL HANDBOOKS,

NEW EDITIONS, REVISED AND ENLARGED.

RURAL ARCHITECTURE; a Series of Designs for Rural and other Dwellings.
THE AGRICULTURAL INSTRUCTOR; or Young Farmer's Class Book.
DOMESTIC FOWL; their Natural History, Breeding, and General Management.
THE FLOWER GARDEN.
HORSES: their Varieties, Breeding, and Management.
DOGS: their Origin and Varieties.
PIGS: their Origin and Varieties.
COWS: and Dairy Husbandry.
THE HIVE AND THE HONEY BEE.
PESTS OF THE FARM.
LAND DRAINAGE, EMBANKMENT, AND IRRIGATION.
SOILS AND MANURES; with Instruction for their Improvement.

London: PIPER & Co., Paternoster Row; Dublin: J. MCGLASHAN, Upper Sackville Street; and all Booksellers.

PROLIFIC PEAS FOR SEED.

THOMAS MARSHALL, Tid Gote, near Wisbech,

HAS now ready for delivery his noted "FAN DWARF MARROW" PEAS, which are the best and most productive yet sown, being excellent boilers and superior for table, either green in summer, or dry in winter. In 1856, *a seed of six pecks per acre produced* 288 *pecks per acre, or* 48 *fold,* and the crop of 1857 is yielding double and treble the quantity of any other sort around.

PRICE 56s. PER QUARTER.

N.B.—Early orders only will ensure execution, as T. M. has but a small quantity disengaged.

KEATING'S COUGH LOZENGES.

"A SLIGHT COLD,"—if its first symptoms are not arrested, too often lays the foundation of a variety of *Pulmonary Complaints,* including *Winter Cough, Asthma,* and other constitutional derangements. The evil consequences of these disorders may be easily averted or subdued by keeping at hand a supply of the above celebrated LOZENGES, which have now stood the test of public experience for upwards of half a century. The Testimonials to their efficacy have been voluntarily given by the most eminent of the Faculty, as well as by all classes of private individuals. Containing neither opiates nor any injurious anodyne, they may be safely taken by the youngest child or the most delicate female.

VALUABLE TESTIMONIAL.

CURE OF ASTHMA OF SEVERAL YEARS' STANDING.

Cainscross, near Stroud, Gloucestershire.

SIR,—Having been troubled with Asthma for several years, I could find no relief from any medicine whatever, until I was induced about two years ago to try a box of your valuable Lozenges, and found such relief from them that I am determined for the future never to be without a box of them in the house, and will do all in my power to recommend them to my friends.

If you consider the above testimonial of any advantage, you are quite at liberty to make what use of it you please. I am, Sir, your most obliged servant,

Thomas Keating, Esq. W. J. TRIGG.

Prepared and sold in Boxes, 1s. 1½d., and Tins, 2s. 9d., 4s. 6d., and 10s. 6d. each, by THOMAS KEATING, Chemist, &c, 79, St. Paul's Churchyard, London. Retail by all Druggists and Patent Medicine Vendors in the world.

N.B.—To prevent spurious imitations, please to observe that the words "KEATING'S COUGH LOZENGES" are engraven on the Government Stamp of each Box, without which none are genuine.

KEATING'S PALE NEWFOUNDLAND COD LIVER OIL, perfectly pure, nearly tasteless, and free from adulteration of any kind, having been analyzed, reported on, and recommended by Professors TAYLOR and THOMSON, of Guy's and St. Thomas's Hospitals, who, in the words of the late Dr. PEREIRA, say that "The finest oil is that most devoid of *colour, odour,* and *flavour,*" characters this will be found to possess in a high degree. Half-pints, 1s. 6d.; Pints, 2s. 6d.; Quarts, 4s. 6d.; and Five-pint Bottles, 10s. 6d., Imperial Measure.

79, ST. PAUL'S CHURCHYARD, LONDON.

NOTICE OF DIVIDEND.

BANK OF DEPOSIT.

No 3, PALL MALL EAST, LONDON, S.W.

Established A.D. 1844.

THE WARRANTS for the HALF-YEARLY Interest on Deposit Accounts, to 31st December, are ready for delivery, and payable daily.

PETER MORRISON, *Managing Director.*

Rate of Interest Six per Cent. till further notice.
Forms for opening accounts free on application.

RICHMOND & CHANDLER'S PRIZE CHAFF-CUTTING MACHINES.

Richmond & Chandler's extensive application of the most approved Steam Machinery in the manufacture of these Implements, afford increased facilities, together with greater mathematical accuracy in every part, obtainable by no other means.

ADDRESS,

RICHMOND & CHANDLER, SALFORD;
BRANCH ESTABLISHMENT,
SOUTH JOHN STREET, LIVERPOOL.

TAYLOR'S CONDITION BALLS.

In packets, 6 Balls, 3s.—3 Balls, 1s. 9d.

Unequalled for Worms, Swelled Legs, Grease, Impaired Appetite, Coughs, Colds, Inflamed Eyes, &c. Read the opinions of the following eminent Trainers.—

"For getting horses into condition they are unequalled."
JOHN OSBORNE.
"In my opinion they are invaluable."—JOHN SCOTT.
"Your condition balls are excellent."—SAMUEL ROGERS.
"I have never used so efficient a ball."—JOHN DAWSON

Prepared by **T. TAYLOR,**
Veterinary Surgeon, Burton-on-Trent,
and Sold by all Druggists.

N.B.—Any gentleman using the Balls may consult the proprietor gratuitously, either personally or by letter.

ESTABLISHED 1812.

TURNIP MANURE. — This valuable fertilizer has been used for the last twelve years with great success by most of the eminent Agriculturists throughout England, and stands unrivalled in the *weight* and *quality* of the bulbs which it produces; it is besides especially beneficial to the *Grain Crops* which follow, while *Clover* is rarely found to fail after the first application. Some of the crops produced by this Manure last year weighed upwards of Thirty Tons per acre. GRASS, BARLEY, CLOVER, and WHEAT MANURES; also BONE, GUANO, and SUPERPHOSPHATE of LIME, warranted of the best quality. Apply to—

H. & T. PROCTOR, Cathay, Bristol.

PROCTOR & RYLAND } Birmingham, Edmonscote, Warwick. And Saltney, near Chester.

CONTENTS.

A Hereford Heifer

The Property of Mr George Pitt of Chadnor Court Pilwyn Leominster, for which the First Prize of £10 with the Silver Medal as Breeder and the Gold Medal as best Cow or Heifer in the Yard, were awarded at the Birmingham Fat Cattle Show December 1856

London Published by Rogerson & Tuxford, 246 Strand 1858.

THE FARMER'S MAGAZINE.

FEBRUARY, 1858.

PLATE I.

A PRIZE HEREFORD HEIFER.

This heifer, bred and exhibited by Mr. George Pitt, of Chadnor Court, Dilwyn, was by Whitenot (1116), dam Pretty-Maid the Second, by Northampton (600). She took, at the Birmingham Show, December, 1856, the first prize of Ten Sovereigns as the best of her class, and the GOLD MEDAL as the best cow or heifer of any breed in the exhibition; Mr. Pitt also receiving a Silver Medal as her breeder.

Proceeding to London, she took, at the Smithfield Club Show, the second prize of Five Sovereigns for Hereford Heifers. She was sold here, to kill, to Mr. J. M. Smith, of Westbury, Wilts, her dead weight was 17 score per quarter.

This heifer also took in her time the following premiums at local meetings:—at Ludlow, in 1854, Five Sovereigns as the best yearling heifer; and in the same year at Leominster, a Silver Cup. In, 1855, at Tredegar, a Silver Cup as the best two-year-old heifer. In 1856, Five Sovereigns, at Ludlow as the best fat cow or heifer; a Silver Cup at Leominster; and another Silver Cup at Hereford; her winnings in all being seven first prizes, and one second.

This heifer, says our own report of the meeting, was quite a wonder in her way as a fat animal. Although somewhat small in frame, she was very remarkable for her perfect proportions, fine head and bone, and prime quality of flesh. She had, too, an extraordinarily good breast, with capital twist, and stood short on the leg. Mr. Pitt, indeed, may well plume himself on being the breeder and feeder of such an animal.

PLATE II.

BLINK BONNY; WINNER OF THE DERBY AND OAKS, 1857.

Blink Bonny, bred by her present owner Mr. W. I'Anson, at Spring Cottage, Malton, in 1854, is by Melbourne, out of Queen Mary, by Gladiator, her dam, by Plenipotentiary, out of Myrrha, by Whalebone.

Melbourne, bred by the late Mr. H. Robinson in 1834, is by Humphrey Clinker, out of a Cervantes mare. He was a good honest race-horse; and, though but roughly prepared, won many heavy stakes against superior fields of horses. As a stallion he ranked unquestionably as the best we have had in this country for many a long day.

Queen Mary, bred by Mr. Dennis in 1843, was put to the stud at three years old. Her first foal was a good filly called Haricot; in 1848 she had a dead foal to Mango; in 1849, Braxey, by Moss Trooper; in 1850, Balrownie, by Annandale; in 1851, a half-bred colt; in 1852, Blooming Heather, by Melbourne; in 1853, Bonnie Scotland, by Iago; in 1854, Blink Bonny; in 1855, she missed to Touchstone; in 1856, Balnamon, by Annandale; and in 1857, Bab-at-the-Bowster, by Annandale. On the decease of her owner, Mr. Ramsay, Queen Mary was sold to the late Mr. Carnegie, of Balnamon; but subsequently repurchased with Braxey and Balrownie at her side for £110. Queen Mary never ran but once, when she was not placed for a two-year-old stake at Chester.

Blink Bonny is a bay mare, inclining in parts to what artists would call a "negative" colour. She stands fifteen hands two inches and a-half high; has a very blood-like lean head, with wide ears, and also great width between the eyes, which are very prominent. She has a strong arched neck, cleanly set into her head; splendid shoulders, good chest, and great depth of girth—being very thick through the jockey's knees. She has immense ribs, a high rump shortening towards the tail, powerful thighs and gaskins, with good bone, hocks, and knees, and short pasterns. Blink Bonny has a blaze of white in the face, giving her quite a family likeness to her famous half-brother West Australian, and a white fore coronet. She has a capital temper, being extremely temperate and docile, while on the other hand she has unfortunately but a thin switch tail, and at the best of times but a roughish dull coat. Making their estimate by these important points, she has been declared by many, who seem to have entirely forgotten her really beautiful head and splendid forehand, to be but a hackney-looking mare. For our own part we have seen few who showed more signs of blood.

THE TURNIP PLANT.

BY CUTHBERT W. JOHNSON, ESQ., F.R.S.

The growth of the turnip plant during the season of 1857-58 has presented to us facts of considerable interest. The periods of long continued drought, followed, during that brilliant summer, by copious rainfalls and a high temperature, have caused the turnips, in most districts, to grow in a very unusual manner. The bulbs, in the instances to which I refer, have grown in *length* to a very irregular extent; but this has not been attended with a corresponding enlargement of the diameter of the bulb. They have commonly extended above the surface of the soil about eighteen inches: these more resemble, in their above-ground shape, the ordinary mangold-wurzel or carrot than the turnip plant. Unfortunately, this morbid growth has been attended with a very extensive diminution of the nutritive properties of the bulb; the stock eat it with reluctance; it seems to possess little or no fattening properties.

Various reasons have been produced to account for the phenomenon. The blame has been sometimes laid upon the seed employed; in other cases, the loss experienced has been attributed to the use, for the turnip crop, of certain well-known artificial manures. To neither of these causes, I believe, can be truly assigned the malformation. I have found, upon extended inquiry, that the elongated turnips have been produced to an equal extent by the plants produced from seed procured of different merchants, from different counties, and from seed ripened on the farm on which it was sown. The seed, then, we may fairly conclude, has had little or no influence in the matter. Then, as regards the use of artificial manures, I find that these long-rooted turnips have been produced to an equally injurious extent on land dressed with farmyard compost only, with farmyard dung and superphosphate of lime, with Peruvian guano and superphosphate of lime, used alone or employed together on the turnip soils of Norfolk and Bedford, Surrey and Dorset, and on lands which have and have not been marled or chalked. We have not, therefore, any reason to believe that the use of any particular dressing has had any influence whatever in the case.

It is ever our fate, indeed, when we are studying the diseases or the growth of plants, to meet with—to be haunted with—suspicions and baseless conclusions, not much more wise than those which bewitched our forefathers. Ever and anon we hear grave suspicions hazarded that the mortality of our sheep is increased when fed on roots grown with artificial manures; the use of sprats in this way has conjured up opinions of this kind. Peruvian guano and superphosphate of lime have been sometimes held to render the turnip less wholesome for the flock. With every effort which I have made to procure reliable evidence on this subject, I have always found that these kind of suspicions could not be rendered more conclusive; they rested, in fact, on the most vague of surmises. The comparative analyses of turnips grown with a variety of manures show that the turnips grown with artificial dressings do not vary materially in composition from the turnips grown with only farmyard dung: the same chemical matters are found in each. Way, Voelcker, Nesbit, and others, all concur in this conclusion. Dr. Anderson's trials were perhaps the most valuable, because the turnips he examined were grown on three kinds of soil, and had been dressed with seven different manures. We can at this time recur to these valuable researches with considerable advantage. For the sake of a more ready comparison, I will give the results obtained by the Professor in the same tabular form to which I have elsewhere reduced them.

In the following table, then, column I. gives the soil and crop; II., the water in 10,000 parts; III., the nitrogen in the fibre; IV., the nitrogen in the juice; V., the phosphates. The turnips were grown on the property of Lord Kinnaird, in Perthshire. The clay soil is the heavy alluvial clay of the Carse of Gowrie, which is a wheat soil of the best description. The hill land is a light loamy soil, of an entirely different character from the Carse clay, and lets at a much inferior rent. The black land forms the boundary between the two former, and partakes of the character of both, those of the clay, however, preponderating:—

I.	II.	III.	IV.	V.
Swedes in 1849.				
Clay land.....	9058.0	2.9	12.9	16.0
Black land.....	9878.0	4.0	14.2	17.6
Hill land	8712.0	1.7	26.8	15.9
Swedes in 1850.				
Clay land.....	9273.0	3.7	8.6	9.6
Black land.....	9278.0	4.0	5.9	9.0
Hill land	9278.0	4.5	10.2	9.8
Aberd'n yellows, 1849				
Clay land.....	9119.5	3.6	15.9	16.2
Black land.....	9047.8	3.8	13.7	16.7
Hill land	9057.8	3.9	24.4	13.3
Aberd'n yellows, 1850				
Clay land.....	9426.3	3.1	7.8	6.8
Black land.....	9059.0	2.9	13.8	12.1
Hill Land	9399.0	3.4	12.0	12.0

In the two next tables will be found the results of some very interesting experiments made with yellow turnips, at Lord Kinnaird's farm of Millhill. The different turnips were all manured with 16 tons of farmyard manure, valued at £4, and had, in addition, quantities of different auxiliary manures. This table gives the number of the experiments and the manure, omitting Nos. 4 and 5, since, owing to the failure of the crops, no analyses of these turnips were made:

0. 16 yards dung.
1. 4 cwt. White's manure.
2. 2 cwt. guano, 2 cwt. salt.
3. 3 cwt. guano.
6. 3 cwt. London Manure Co.'s manure.
7. 4 cwt. superphosphate.
8. 3 cwt. guano, 1 cwt. superphosphate, diluted with 200 gallons water.
9. 3 cwt. superphosphate, diluted with 200 gallons water.

In the following table, column I. gives the number (referring to the preceding table) of the experiments, II. the quantity of water found in 10,000 parts of the turnip, III. the ash, IV. the protein compounds, V. the fibre, sugar, &c., and VI. the nitrogen found in these differently-manured turnips. No analyses were made of Nos. 4 and 5, as the gain was not equal to the cost of the manures:—

I.	II.	III.	IV.	V.	VI.
0	9327.0	39.6	83.8	549.6	13.2
1	9287.0	67.0	63.5	482.5	10.0
2	9411.0	55.0	68.5	465.5	10.8
3	9345.0	58.0	82.5	514.5	13.1
6	9285.0	76.0	95.8	543.2	15.5
7	9243.0	59.0	73.0	625.0	11.0
8	8862.0	75.0	117.4	945.0	18.5
9	9509.0	56.2	41.3	399.5	6.5

It would seem, therefore, that there is not such a difference in the composition of the turnip plant grown by different manures, as to lead us to conclude that any injurious results would ensue from them to the stock.

There is no doubt considerable results are to be obtained from small variations in the *mode of applying* the same kind of food. We have an instance of this in the good effect of slicing or of pulping turnips, a very useful report on which, by Mr. J. M'Laren, of Rossie, will be found in the last number of the "Transactions of the Highland Society of Scotland," p. 153. His trials were made in 1855-56 and 1856-57, with six cattle fed on whole turnips; six fed on pulped turnips, mixed with cut straw, and given fresh; and six fed with pulped turnips, mixed with cut chaff, and allowed to ferment for forty-eight hours. From the results of these trials he fairly enough draws the conclusion, "That, although there has been some variation as to the largest increment, this season, it being on the lot consuming unfermented pulp, whilst last year these were much in arrear, still the general result has been that the pulping of the turnips is a saving of the root in feeding cattle. At the same time, it is not to be forgotten that, in a feeding experiment, much depends on the accident of a well or an ill-feeding beast being in one or other of the lots. It is, indeed, almost impossible to find any two animals feed alike, however well selected or attentively looked after; still the average of six cattle in each lot should give a pretty fair test to judge by; but one set of trials can hardly be held to be conclusive in determining either success or failure of any system." The following were the results obtained in 1855-56:—

	Weighed Oct. 18, 1855. cwts.	lbs.	Mar. 1, 1856. cwts.	lbs.
6 fed on pulped turnips, mixed with chaff, and fermented	70	14	82	28
6 fed on whole turnips	70	24	81	77
6 fed on pulped turnips and chaff, given fresh	70	70	81	14

Upon repeating the trial in 1856-57, with the same kind of short-horned steers, the

	Weighed Nov. 8, 1856. cwts.	lbs.	April 9, 1857. cwts.	lbs.
6 fed on whole turnips and straw ..	54	54	75	0
6 fed on pulped turnips, given fresh, mixed with chaff	54	68	79	28
6 fed with pulped turnips, mixed with chaff, and fermented.....	54	28	78	7

After making all the necessary deductions, he found the profit from feeding these different lots in 1856-57 was

Lot 1	£15	17	4
„ 2	23	15	10
„ 3	22	14	4

The successful growth of the turnip, indeed, is one of the most important of the farmer's many anxious efforts: anything, therefore, which adds to his stock of manure for this root, adds, in fact, almost directly to the food of his live stock. I have long urged upon their attention the collection, for this purpose, of the couch and other weeds, which ever follow, as it were, the plough on all arable soils. I have reminded them from year to year of the valuable compost produced by collecting these into heaps, and mixing them with copious dressings of common salt or lime. By this process, a very considerable amount of the organic matters of the

weeds, which are usually lost in burning, is restored to the soil. Even the ashes or mineral substances of these weeds contain valuable fertilizing matters. All the weeds from an inferior turnip soil, when collected and burnt in a heap, yielded a considerable portion of ashes. These ashes, when analyzed, were found to contain of

Potash	8.6	per cent.
Soda	4.2	,,
Lime	15.1	,,
Phosphoric acid	10.9	,,

Being aware of these things, it was with much pleasure that, on a recent occasion, near Ipswich, I noticed some noble teams of those Suffolk-punch horses drawing waggon-loads of salt out of the town. Upon my asking one of the waggoners what these lots of salt were intended for, he informed me in the interval between a "Gee whoi!" and a whistle, "We puts it on to the spear-grass."

Upon a subsequent occasion, I found one of these huge gatherings of weeds carted and neatly dressed, and shaped like an ordinary compost heap, pressed pretty solid by the action of the cart and horses, and copiously covered with salt. Here I felt was indeed the making the most of uninvited, unwelcome visitors—robbers of the food intended for better and more honest plants. Of the compost thus prepared, I find that it is deemed by these skilful Suffolk farmers to be useful for all root crops; and although I could not find that it had been used in any *comparative trials* for mangolds, still I cannot but conclude that, from the salt and other matters which it contains, it must be a powerful manure for this valuable and increasingly-cultivated root.

Such are a few only of the practical movements in the growth and use of the turnip crop, which have occurred during the last few months. The retrospect adds fresh evidence not only of the many mysterious and injurious affections—not to say diseases—of our cultivated crops, but is also suggestive of the certain fact, that not only is something considerable yet to be generally accomplished in the collection and preparation of home-made manures, but that when, after escaping loss of plant, diseases, malformations, and stunted growths, the bulbs are fairly stored—that, after all, something profitable is yet to be ascertained relating to the consumption of them by our stock.

THE ROYAL AGRICULTURAL IMPROVEMENT SOCIETY OF IRELAND.—The Waterford local committee have placed at the disposal of the Society a Challenge Cup, value one hundred guineas—to be competed for at every annual meeting: "for the best lot of three short-horned animals—bulls or heifers, but not in mixed lots—not exceeding 20 months old, having been bred by the exhibitor, and *bona fide* his property. Animals specially entered for this prize not to be disqualified from competing for the premiums offered for their section in the short-horned bulls."

WHAT SHALL WE DO WITH OUR SPROUTED WHEAT?

In the sales made in the Edinburgh Corn Market of Nov. 25, I observe that of the 667 quarters wheat sold, just one-half—say 332 quarters—were sold at prices varying from 23s. 6d. to 36s. per quarter, while other 108 quarters were sold at from 36s. to 40s. The first 332 quarters we may safely assume to be grain which had been exposed to the September's rain, and had become so sprouted as to be unfit for human food. The 108 quarters we may consider as having been also exposed to the same storm, but to have escaped with less damage, and to be fit for mixing with fine wheats for the manufacture of second bread and biscuit.

This proportion of 440 damaged out of a total sale of 667 quarters will, I believe, represent the average state of the wheat crop through the eastern counties of Scotland, and the northern ones of England.

The sale by farmers of the qualities bringing 36s. to 40s. is, perhaps, the best way of turning them to account; but it is matter of serious consideration whether the portion so deteriorated as to fetch but 23s. to 36s. could not be more advantageously turned to account on the farm.

There have been but few experiments made with wheat as a feeding substance for animals; indeed, I can find no record of any such experiment, the reason being that for several years past, during which the attention of scientific and practical men has been drawn to the comparative values of different articles for stock feeding, the price of wheat has been so high, and, until 1856, its quality so good, that it would have been thought madness to apply this "nobler grain" to any other purpose than the supply of the bakers and their millions of customers. But two disastrous harvests have flooded Scotland and Northern England with damaged wheat, of the type sold as above in the Edinburgh market; and we may take it for granted that, behind even that poor display, there are many quarters still more deteriorated. *What shall we do with them?*

In comparing the composition of wheat with other grains, on the data given in Johnston's *Elements of Agricultural Chemistry* (sixth edition, pp. 340 and 341), I find the following results—

	Sugar, Starch, &c.	Gluten, &c.	Oil.
Wheat, in each 100 lbs.	55	12	3
Barley ,,	60	13	2.75
Oats ,,	50	14.5	4.8
Beans ,,	40	26	2.5
Oilcake ,,	39	22	12

This places wheat in no disadvantageous light as compared with the other grains for meat-producing qualities. The effect of sprouting would be rather favourable than otherwise, as it would change a portion of the starch into sugar; the latter more easily assimilated by the animal; while the *diastose* formed during germination is believed, as in the case of malted barley, also to add to the solubility and nutritiveness of the food.

These are *theoretical* recommendations of sprouted wheat as a food for live stock. They place it at least on a par with barley, which has been largely used for that purpose, when at a price exceeding that at which the wheat described is at present sold. There may, however, be *practical* objections; and my design, in calling the attention of yourself and your readers to the subject, is to elicit these objections, if there be any.

Would you, therefore, state your own opinions on the subject, and invite your correspondents to consider and discuss it also? S.

NOTES ON NEW IMPLEMENTS AND MACHINES EXHIBITED AT THE SMITHFIELD CLUB SHOW OF 1857.

Once more have we encountered the confusion and the crush of the implement galleries of the Baker-street show. Right pleasant was it, nevertheless, in spite of all the disadvantages attendant thereupon, to witness the interest taken in the mechanism displayed, by burly farmers and well-to-do agriculturists. Nor less pleasant was it to be informed, amidst the crush of commercial combinations, and the gloomy forebodings of "cotton men," and men of other substances nameless here, that something more than a passing interest was taken, as was evidenced by the comparatively well-filled "order books" of some of our leading firms. Truly, in their quiet unostentatious progress, and in their freedom from the shocks of panics and the untoward turns of trade, our agriculturists have little need to envy the position of their commercial brethren. In view, however, of the rising importance of the implemental department of the show, fast treading on the heels of its more imposing rivals, one could not help—amidst the bustle and the buzz which prevailed—feeling it to be a pity that the expansive capabilities of the space for exhibition were not coincident with those of the exhibition itself, and that something could not be done to have it held in some place commensurate with its importance. The present galleries *may* be termed places for the *exhibition* of implements and machines; places for their *examination* in no wise are they. The close proximity in which the machines were *huddled* together was subversive of all attempts at examination of their details of construction or principles of arrangement; indeed, the feeling raised by a survey of the various "stands"—so called, we suppose, on the principle of *lucus a non lucendo*—was surprise at the ingenuity which could, in such limited spaces, cram so many and such bulky articles.

The time has gone by, when the farmers were satisfied with a mere look at implements and machines; passing them over, as if careless of their uses to them; or if purchasing them, doing so on the faith of the opinion of some friend, or the statements of the manufacturer. By the gradual increase in the number and in the importance of the objects of our agricultural shows, we have been educating the farmer in the uses and value of mechanism; and, no longer dead to the aid which it can afford him in his various operations, he is anxious to see new things, and careful to examine their claims to support. Hence arises the value of well-ordered exhibitions, in which every facility is granted to examine the details of all machines there exhibited. And hence also arises the value of well-arranged catalogues, in which the various machines manufactured by the several firms shall be clearly, that is mechanically illustrated and described. We of course refer to the trade catalogues issued by the respective firms not to the catalogues issued by the show or shows at which their machines are exhibited. In view of the advantages of a catalogue in which mechanical descriptions and accurate detailed illustrations would be given, it is certainly curious that no firm, so far as we know, has yet brought out one in which this species of information has been displayed so fully as the importance of the subject demands. The advantages obtained by the use of such catalogues would be as much on the side of the manufacturer as on that of the purchaser. Makers of manufacturing mechanism in our cotton districts know this well; and although they do not issue catalogues in the manner of our agricultural implement makers, still, when they have anything new to bring before the notice of the manufacturers, they take care in their circular or prospectus to illustrate mechanically and describe clearly the details of their invention and the principle of its operation. And this they do, knowing that the parties who may be the purchasers are well acquainted with the operation of the machine which the new candidate for their favour is designed to supersede; and that consequently what the manufacturer wants is information which can enable him to decide in what respect the new machine is calculated to do better work than the old, or how the machine presented to his notice by one maker is better than that brought forward by the rival trader. Are the machines or implements used by the farmer, because they are less costly or complicated than manufacturing mechanism, less important to him? or is he presumed to be indifferent to their details of construction, or principle of operation? or is it supposed that he cannot understand or appreciate mechanical description? These questions we do not venture to answer; but true it is that the more facilities are thrown in his way to understand fully the nature and operation of the mechanism which he is desirous to buy, the more readily will he become a purchaser. We have said that the time has gone by when the intelligent farmer will be satisfied with a bare look at machinery; a thorough examination alone satisfies him: and the more readily the manufacturer throws facilities in his way for this thorough examination, the more will they find it redound to their own interest. It is impossible to overrate the uses of well-arranged catalogues in enabling farmers to examine quietly, and at their leisure the peculiarities of machines which may have attracted their attention at the shows which they may have visited. It is easy to conceive what close attention would be given to the detailed descriptions of a machine which a visitor and an intending purchaser *saw*, but could *not examine*, midst the crush and confusion of the Baker-street show. We have ventured thus far to detain our readers with remarks on this subject, because we conceive it one of considerable importance, and because we happen to know that with many practical agriculturists it would be a matter of congratulation if they were enabled to examine leisurely the construction and operations of machines in which they felt an interest.

Not longer to keep back the more immediate subject of our paper, we proceed to notice a few of the new, or comparatively new, implements and machines exhibited, following as closely as possible the natural order in which the agricultural mechanism is used in practice, beginning with cultural implements, and ending with the mechanism used for the preparation of food for stock.

(1.) In the department of cultural implements we have little new to notice. Mr. E. Clarke, of Great Badley, Essex, exhibited a "furrow-opener and slide," invented by Mr. Wm. Delfe. The cultivating part of this implement bears a resemblance to "Bentall's broad-share;" and the lever movement by which it is raised, when it reaches the end of the stetches at the headlands, is a modification of that used in Garrett's horse-hoe. The implement is supported in front by a small wheel, and at the rear end of the frame or beam by two

wheels of larger diameter. These wheels have their bearings at the extremities of two levers, jointed near their centre to the beam of the implement. The free ends of the lever are continued upwards, and passed through the slots of two curved or segmental guides, provided with holes and a catch-pin, by which the levers are kept in any desired position. Chains are connected to the upper extremities of the levers, and carried over and fixed to the peripheries of two eccentric wheels, keyed on to a shaft working in bearings supported on the outer extremities of two curved brackets projecting from the ends of the beam. The stilts or handles of the implement are placed between these brackets; and a cross handle, attached to the shaft bearing the eccentric wheels, is thus placed easily within the reach of the attendant. By turning this cross-handle in one direction, the chains are wound round the peripheries of the eccentric wheels, and the upper extremities of the two levers supporting the wheels pulled towards the attendant. The action lowers the ends of the levers to which the wheels are attached, or rather, tends to press the wheels against the ground; and the leverage thus obtained raises the implement out of contact with the ground. Behind the body of the implement, which acts in the soil, two wings are placed, which expand outwards, and spread the soil and manure over the land.

(2.) To their well-known liquid manure drill Messrs. Reeves, of Bratton, have adapted this season the "drop drill" invented by Mr. Chambers, the gentleman to whom the agricultural world is indebted for the "broadcast manure distributor." The simple mechanism of Mr. Chambers is confined entirely to the coulter part of the drill, so that it is capable of being applied to any form of water drill. There is little diversity of opinion as to the desirableness of a "good drop drill for root crops." The difficulty hitherto attendant upon all attempts to perfect a machine of this class has been caused by the employment of dry, dusty manures, by which the chances were lessened of the seed germinating, in dry seasons. By the use of liquid manure, deposited (along with the seed) at intervals, and not in a continuous stream, Mr. Chambers obviates the difficulties attendant upon the system as hitherto tried; and the following advantages are obtained: 1, A saving of two-thirds the quantities of water now applied, thereby making the drill applicable on light-land farms, where water is scarce; 2, A saving of half the quantity of seed; 3, A saving of manure, from its being deposited only where required; 4, Where land is clean, a saving of one hand-hoeing; 5, The certainty of having the best plant in the right place, and thereby obtaining a decided increase of produce. The mechanism by which these advantages are obtainable is remarkable for its simplicity of action, and the absence of all complicated parts liable to derangement. The following brief description may suffice to explain its peculiarities of arrangement: A hollow rotary chamber, provided with four arms or spouts, revolves on an axis supported on bearings fixed to a frame, attached to the drill, in place of the ordinary swing lever and coulter. The spouts project from the periphery of the hollow chamber; and through these the liquid manure and the seed are passed, to be deposited in the ground as each spout or outlet comes in contact with it. The liquid manure and seed are delivered to the interior of the chamber by means of a spout, which is also carried by the frame. The successive deposits of seed are made in a furrow, formed by a coulter, which precedes the wheel, and is adjusted in the usual manner. The hollow chamber receives its motion through the medium of a wheel running on the land, and which is keyed on the same shaft which supports the hollow chamber. The distance between the outlets of the spouts of the hollow chamber being invariably uniform, the intervals between the deposits of seed will be uniform also. To obviate this defect, however, and give an adjustability to the mechanism, so as to enable the distance between the seed deposits to be regulated as desired, the wheel which gives motion to the chamber is made in segments, each of which is attached to one of the spokes, or arms, provided with slots and bolts, and nuts, by which they can be adjusted nearer to or further from the centre, thus reducing or enlarging the periphery of the wheel. So effective is this simple mechanism which we have now described, that the wheel can be made to rotate even at a very high velocity, without in any way impairing the integrity of the alternate or intervallic dropping, each deposit having its proper modicum of seed and liquid manure, and being perfectly independent of the preceding and succeeding ones.

(3.) Messrs. Reeves also exhibit, in addition to the liquid-manure and drop drill just described, a simple hand-drop drill, which seems likely to be useful for market gardens and small occupations. The main feature of the apparatus may here be described. To the framing, which runs on two wheels, and is worked by a cross-handle, the seed-chamber is fixed; this being formed of a vertical cylinder, some three or four inches in diameter and six or eight in height. The lower part of this is capable of being placed very near to the ground while the machine is in operation, and this facilitates the "bunching" and depositing of the seed. In this seed-chamber a circular plate, or partition, of cast-iron is placed horizontally, provided with a ring or a series of apertures of determinate size. In close contact with this plate another, similarly perforated, is made to revolve by simple mechanism. While the solid parts of the upper and revolving plate, on which the seed placed in the chamber rests, are opposite the perforated parts of the partition or plate below it, there is no passage downwards for the seed; but as soon as the perforations of the two plates coincide with each other, a passage is made for the seed, which drops down through the lower part of the chamber, and is deposited in the ground at intervals corresponding to the number of holes in the plates and the rapidity with which the revolving plate is made to rotate. Various plates are used, according to the kind of seed which it is desired to deposit. A coulter is placed in advance of the seed-chamber, to form a furrow, in which the seed is deposited.

(4.) In addition to the machines already noticed, Messrs. Reeves exhibited a specimen of Mr. Palmer's rotary corn separator or screen, for which, we believe, the first prize was awarded at the York Show in August last. As this machine presents several features of considerable novelty, we propose to give a brief description of it. In general appearance it resembles the well-known barley hummeller of Messrs. Garrett, the main feature being a rotary cylindrical screen or sieve, the shaft of which is placed at an angle, and is turned by means of a winch or handle, or through the medium of a pulley, if steam-power is used. The meshes of the cylindrical screen are made of four different gauges, the coarsest of which is at the delivery, and the finest at the feeding end. Below these divisions of gauge, shoots or spouts are placed, to conduct the products of the various screenings to suitable receptacles. Thus the first spout receives from the finest gauge of the screen the small dust and seeds, the second spout from the next finest gauge the very thin corn, the third spout receives the tail corn, while the last receives the best. Poppy heads, and other bulky substances which will not pass through the largest meshes, are received into a fifth shoot. But the main feature of the machine consists in the adaptation of a series of segmental partitions or plates to the interior of the cylindrical screen; these fitting close to the inner periphery, and arranged at dis-

tances from each other of one-and-a-quarter inches, so as to extend from one end of the cylinder to the other. As these partitions revolve, they drag the grain up the side of the cylinder, but not over or round the shaft or centre. As the cylinder in its revolution carries round these partitions or segmental plates, they dip into the corn lying on the under side of the screen, and rubbing against it, tend to arrange the individual grains on a line with the meshes, and to facilitate their escape from the screen. The action of the plates is also to spread the corn over a large surface of the screen, giving a greater operating surface than is usually obtainable in ordinary revolving screens. The simple means here adopted has also, it is said, the effect of obviating the defect of ordinary winnowing machines, namely, the passing of "kernels" or "pickels" of the same specific gravity as the best corn, but which are smaller and thinner in size. Mr. Palmer informs us that his machine effectually overcomes this difficulty. To keep the meshes of the screen clear, a brush of steel wire is applied at one side and near the upper part of the cylinder. Messrs. Reeves make the wires of which the brush is composed curved; this increases their elasticity, and enables them better to thrust inwards any grain, seeds, or other substance which may get fixed between the wires of the screen, or be carried up to the level of the brushes.

(5.) In this class of machines we have to notice another novelty, namely, the "adjusting screen" of Mr. Roby, whose "corn screen" is well known to many of our readers. By a simple arrangement the distance between the wires of the screen can be adjusted so as to suit different sizes of grain. If the reader will imagine two tiers or series of wires placed parallel to

o o o o o o o
o o o o o o o

each other, the upper row or series of which is fixed, forming the permanent screen over which the grain passes, while the wires of the lower row or series are capable of being moved simultaneously from side to side, so as to occupy any position between the wires of the upper row, thus—

o o o o o o o
  o o o o o o o

he will have some notion of the method by which different gauges or width of spaces between the screening wires are made, so as to suit different sizes of grain. The necessary adjustment is very easily made.

(6.) We may here notice, as closely connected with this department of mechanism, the barley aveller, or hummeller, exhibited by Messrs. Barnard and Bishop, of Norwich, and invented by Mr. Holben. Our readers are doubtless aware of the "hand hummeller," consisting of a square frame of iron, open at top and bottom, and two of the sides of which are connected by a cross or curved bar carrying an upright handle. The space between the sides of the frame is filled up with cross divisions of the same depth as the sides of the frame, and so arranged as to form a series of square cells, open at top and bottom. The barley, to be got rid of awns, is placed on the floor of the barn; and the frame with its divisions worked by means of the handle gently up and down amongst it. The friction of the thin edges of the frame and its divisions on the grain, and of the particles of grain upon each other as they are forced up into the cells, gradually removes the awns. Mr. Holben takes this contrivance, and in place of working it by hand, gives it a reciprocatory motion up and down by means of a cranked shaft, to the end of which a fly-wheel is keyed on; and to the other a small pinion, which engages with a spur wheel, put in motion by an ordinary winch handle. To the frame-work supporting this mechanism a hopper, with regulating or feed-plate, is connected. The barley to be avelled is put into this, and is passed at the rate of from ten to twelve quarters per hour, in a thin stream or layer, below the reciprocatory frame with its square cells.

An adaptation of this apparatus to a winnowing machine was also exhibited. In this a series of elevators take the grain as it is passed from the winnowing-machine, and carry it up to the hopper, from which it is passed to the hummelling frame.

(7.) Mr. Simpson, engineer, of Petersham, Surrey, exhibited a new hay and straw band-making machine, which presents some features worthy of notice. The apparatus consists of an oblong frame, supported on four standards; in the centre of the frame a shaft, with fly-wheel and small pulley, revolves in bearings. From the small diameter pulley fixed on the shaft, power is taken, by means of a belt, to two other pulleys of same diameter, fixed on the shafts revolving in bearings near each end of the framing. To the outer extremities of each of the shafts the hook, to which the hay or straw to form the band required, is attached. Under ordinary circumstances the hooks do not revolve, although the shafts to which they are connected may be revolving; but as soon as the straw or hay is attached, and the "drag"—made by the operator as he walks outward from the machine—put on, the hook is pulled outwards till it engages with a catch on the driving shaft, and it immediately partakes of its motion; on the "drag" being stopped, the hook is pulled out of connection with the catch of the shaft by means of a spring. By this arrangement three separate lengths of bands may be made; and as each hook is in a quiescent state when no band is attached to it or dragged on it, should one operator be finished with his length before another, he can commence a new attachment to the hook without necessitating the stoppage of the other two, which would be the case if the hooks had no movements independent of the shafts to which they are attached.

(8.) In the department of machines for the preparation of food for stock, we have little novelty to describe. Mr. Bentall exhibited his patent root pulper. As this is a comparatively new machine, we may here shortly describe it. Its main feature is the employment of a central barrel or drum revolving in the lower part of the hopper which receives the roots on which the machine operates, in close contact with, and parallel to, a small worm or archimedean screw. The large barrel or drum is provided with a series of projecting teeth of a hooked or curved form; these are not arranged in parallel lines in the periphery of the drum, but are set spirally, forming a helical line, the pitch of which corresponds with that of the small archimedean screw noticed above. To one end of the shaft of the central barrel or drum the fly-wheel is keyed on, to the other a spur wheel engaging with a pinion fixed on the end of the archimedean screw shaft. As the screw revolves, the thread or blade passes continuously between the projecting teeth of the drum, and the combined action thus resulting, the tearing of the teeth and the lateral or side squeezing of the blade of the screw, rapidly reduce the roots subjected to it to a fine pulp. As the projecting teeth of the drum are not cast on it, but are wedged into slots or apertures provided in its periphery, should any break they can easily be replaced by new ones.

(9.) In the department of chaff-cutters, Messrs. Richmond and Chandler exhibited a new form, which is noticeable for its compactness of parts and neatness of

appearance. In its mechanical arrangement it is similar to their well-known chaff-cutter, and is characterised by careful workmanship.

(10.) Mr. W. Snowden, of Longford, Gloucester, exhibited a chaff-cutting machine, which possesses considerable novelty of detail, and is worthy of attention from the ease with which a single attendant can work a large machine. The principal peculiarity is the absence of feed-rollers, and toothed gear. The hay and straw are only passed outwards when the knife is out of contact with them, so that no power is lost in the material pressing on the knife. The whole length of the box (seven feet) acts as the bottom feeder, and by a simple adjustment of a thumb-screw, different lengths can be cut, varying from $\frac{1}{4}$ of an inch to $1\frac{1}{2}$ inches long. The bottom feeder consists of an endless cloth, revolving on back and front rollers. To the front roller a ratchet wheel is attached, to which motion is communicated by a lever and catch, that being moved by a pin placed in the front frame of the machine. This frame has a reciprocatory movement given to it through the medium of a crank, worked through the agency of the fly-wheel which carries the cutting knives. The front frame is provided with a cross bar, to the centre of which a stud is fixed; to this stud the end of a cross lever is jointed; this lever is carried backwards a short distance, and is jointed at its other extremity to a stud fixed in the centre of an iron block, which acts as the top feeder, and which moves up and down in grooves made in the sides of the framing of the machine. This iron block carries a revolving roller midway between the lever. Jointed at either end to the front frame with the iron block, another lever placed at right angles to it is fixed. This lever is nearer the front frame than to the block. Pivots are provided at each end of this cross lever, to which a board, called by the inventor the pressing-board, is attached; as this pressing board is not under the control of the crank, it presses on all thicknesses of material, from three to seven inches, passing out to the action of the cutting knife, and the iron block sliding in a groove accommodates itself also to all the thicknesses. When the iron block goes down the pressing-board rises up, so that the iron block acts alternately as feeder and presser. R. S. B.

THE ADVANTAGES OF LEASES.

On the 30th of December last this question was brought under discussion at the monthly meeting of the Winfrith Farmers' Club. The subject stood as "The Advantages of Leases; Security to the Tenant an Inducement for the Outlay of Capital."

Mr. READER, after a few introductory remarks, said the subject for that evening's discussion was a most important one, as it affected the whole farming interest of England, who, he was informed, had, some years since, over £6,000,000 invested in lands, which amount was increasing year by year, as improvements took place. The question for their general consideration would be: "Were any advantages to be derived from leases? Were they inducements for the outlay of capital? Who would be benefited by leases? And would any parties be injured by them?" He trusted that they should prove by their discussion that they were not actuated by any selfish motives or hostility towards any party, but that their arguments were intended to improve the state of agriculture in general, which must necessarily improve the position of the landlord, the tenant, and labourer. He thought no one would deny that the most practical landholders of this kingdom long since saw the necessity of giving to the tenant a security for his outlay, as an inducement to invest his money with cheerfulness in every acknowledged improvement. For instance, the late Lord Leicester, the Earl of Yarborough, and the Duke of Bedford, he believed, adopted the system of leases, coupled with a tenant-right at the end of it; and he (the speaker) was also credibly informed that neither of the two first noble personages alluded to, ever had to pay one shilling for those very great improvements which had been acknowledged by all to have been made upon their estates; for they had always found their tenants ready and willing to pay for them themselves. Now, he would ask, where was the gentleman to be found who had improved his property to the same extent, at so small a cost, under the tenant-at-will system? The late Mr. Pusey likewise saw the necessity of a change, and brought his famous tenant-right bill before the House of Commons on various occasions; and although it was rejected on its first appearance by a large majority, it gradually gained favour, and was twice carried through the Commons, only to be rejected by the Lords. He believed, however, if that worthy man who introduced it had only lived a few years longer he would have seen it become the law of the land. Again, let them consider also what that eminent man, Judge Gale, said on this subject at the Botley Club two years since: "I need not enlarge," said he, "on the absolute necessity there is that the tenant should be protected by securing to him a lengthened time in the possession of that land which, on all sides, he is urged to improve by an investment of capital in it." Another paragraph said, "The objects to be sought for in a lease are security to the landlord and a freedom of action to the tenant. The landlord desires to have security that the land shall not be improperly cultivated, and the tenant that he shall not be restricted in making the improvements which his *soi-disant* friends are so liberally urging him to make." Then he had the authority also of a practical man (Mr. Stares, of Droxford) for saying that numerous existing leases prescribed a course of cultivation which was simply absurd. By a tacit consent these were commonly disregarded; and the consequence was that the tenant would be better off without a lease at all, as such a lease puts him, at all times, at the mercy of the landlord, and, indeed, was of no use but to put a fee into an attorney's pocket, for copying a senseless document, originally prepared in the dark ages of agriculture. He (Mr. Reader) had brought forward these remarks in order to prove that the practical landholders had been prepared for a change in the tenure of land for a long time past, having no doubt themselves seen the difference in the improved culture of the land which had been secured to the tenant for a lengthened period over that held from year to year—except occasionally, where a fair and equitable tenant-right had existed. If such gentlemen as the noble lords he had before alluded to could see the necessity of giving security to the tenant for his outlay of capital as an inducement to invest more capital, and to improve their land in every respect, when the general system of farming, more especially in the west, was—

To plough and to sow,
To dress in and mow;
Then harvest and thrash,
And market for cash,

was not that necessity increased five hundred times over, when thousands of pounds were annually expended in this county alone upon artificial manures, and thousands more in feeding stuffs, a large portion of which could not be returned for years? He believed there were farmers in this country who paid more every year for those manures and feeding stuff than ever their rents amounted to—to say nothing of the extra amount of labour this must necessarily entail. They had had bones in use as a manure only a few years, comparatively speaking, and, if he remembered rightly, guano was first imported into this country about the year 1836, by Gibbs and Co., which sold at about £6 per ton. Since that time, however, a better quality had been found, and now, he believed, the importation amounted to upwards of 240,000 tons. Then there was superphosphate, the general manure for the root crop, the quantity used being beyond description. He was credibly informed that over £25,000 a year was spent in the county of Dorset alone upon artificial manures. He found

that although linseed cake had been used extensively in some of the upper counties, where security was given for the outlay, for some years past, it had only been introduced here about ten years since, by Mr. Virtue, the agent of Dixon and Cardus, and its sale, though small at first, had gradually increased year by year. Then, again, there were so many other sorts of feeding stuffs sold in the market, such as Indian corn, lentils, &c., &c. Now, if they took it that Messrs. Dixon and Cardus, by their agent, sold 1,000 tons of linseed cake, and estimated that sold by other firms at 1,000 tons more, at about £11 7s. 6d. per ton, they would have an amount equal to that spent in manures besides all the other feeding stuffs named. He (the speaker) would ask them whether this quantity might not be doubled, nay trebled, and made to pay a good interest, provided tenants could be insured in their holdings? They often saw where money might be laid out advantageously, if parties were only sure of keeping their farms for a certain number of years; he believed, moreover, that if leases were generally adopted, they would see machinery increase to a very great extent. If a man were secure in his holding, he would doubtless adopt every modern principle of improvement, both in culture and implements; in fact, he would expend on the farm every pound at his command, provided he could see any chance of getting something like a return for his outlay, even though it were ever so far distant. He would endeavour to improve his farm in every possible way; he would likewise see the necessity of turning his attention to the improvement of the labourer, knowing full well that if attention were paid to his comforts, for every little sum of money he might lay out he would be sure to be amply repaid. If they were to have machinery introduced among them, as in Scotland, they would find that they must have an improved class of men for the management of it. Now, he would ask why was it that the Lothians of Scotland were held up as an example to follow, and how came those parts to be so well cultivated? Why, the fact was this—the tenants had security for their capital, either by way of lease or tenant-right. Mr. Reader then referred to a communication which he had received from a friend in Scotland, regarding the holdings of tenants. The writer, after drawing attention to a town on the borders of Selkirk and Roxburghshire, near which a small stream empties itself into the river Tweed, says: "The country to the north of this is mountainous, and presents a very rugged and barren appearance, and is in many places so steep as to render cultivation impossible and most difficult. Its rocks contain no fossil of any description, and are very hard; covering them, however, to various depths, is a deposit of clay, of various degrees of tenacity. In some places, where the underlying rocks are more brittle than in others, the soil works easily; in others it is very difficult to reduce it to good tilth. It nearly all requires to be drained; and when this is performed, and lime applied at the rate of about four or five tons per acre, it will grow very good crops of roots, grass, and corn. Not a great many years since the only cultivation on the borders of the stream already mentioned was a mere strip of oats, and occasionally a little barley. Now large fields are brought into cultivation on the steep sides of the mountains; and where a few years ago only stunted heather, bad grass, and a little furze formed the only productions, are now grown excellent crops of corn and roots. One can frequently see two men sowing together, one of whom sows oats, the other guano, despite its price. On most of these farms there is a steam-engine fixed, which is the property of the tenant; and by the goodly rows of feeding sheds, it is at once evident that great attention is paid to beef-making. The greater proportion of the draining of late years is done by Government money, for which the tenant pays 6½ per cent.; but a large breadth is drained by the tenant, at his own expense, excepting the tiles. Without one exception, the whole of these farms are held on leases of considerable length—generally for 21 years—and the majority of the occupiers do not expect to derive any profit until after the lease is half expired. Most of them make a good return for the money laid out, and nearly all contribute greatly to the general improvement of the district. Fixed for so long a period in one place, a complete identification with local and parochial affairs, and a permanent interest in the labouring class, are fully secured; while all the time the tenant feels quite at home, and perfectly independent, quietly pursuing his course, and year by year adding section after section of the rugged steep to the cultivated portion of his farm. He feels he has confidence in himself, his soil, and the means employed; he regards his landlord with feelings of respect. It is impossible that such land could have been cultivated by tenant farmers without leases; nor without them would men of capital and skill have been attracted to so unpromising a district. Much as the Lothians have been talked about, and high as is the position to which they have risen in the agricultural world, there is nothing there which speaks so forcibly, or which proclaims so unmistakeably, the advantages of long leases, as the higher districts present; and where we find cultivated farms, of 300 or 400 acres in extent, where twenty or thirty years ago not more than one-third was under the plough, and that the breaking up still continues—where we find the face of the country so changed—where we find everything altered, save one, namely, the relation of landlord and tenant, and that secured by a tough bond of 21 years' length—where we find time only deepens the impression that such long terms tend to the benefit of all concerned—there need be little hesitation in recommending a similar bond to the notice of all parties, and more especially to those who are compelled to farm under the unsatisfactory tenure of one year. Many instances could be named wherein the land which produced, only a few years since, poor grass, heath, and broom, and which was not worth 1s. 6d. per acre, is now considered cheap at 15s. per acre. I have just heard of an instance where, on a farm of 1,000 acres of arable land, the tenant has expended, one way and another, over £15,000, and hopes he will be repaid with good interest before his lease expires. Of the indirect benefits of such a system it is needless to say a word, as they are patent to all." Mr Reader then proceeded to say that he thought this communication from Scotland quite sufficient to prove the desirability of long leases. They had often heard of Scotland, of Norfolk, of Nottingham, &c., as being well farmed, and examples worthy of following, but they did not tell them the cause of this good farming. They did not tell them that security was given to the tenant, either by way of lease or tenant-right. The system of making tenant-right at Nottingham was this: For bones, one-sixth after a crop of turnips, the whole cost and carriage; after one crop of corn deduct two-sixths; after one crop of corn and grass mown, one-half; after one crop of corn and two of grass, four-sixths; and after two crops of corn and one year's grass, three-fourths. For lime allow for two crops the whole value and labour before a crop, and half labour after one crop. For all artificial manures, such as guano, rape-dust, superphosphate of lime, &c., one-third, without carriage, after one crop of corn or grass mown. For linseed cake one-fourth of the bill for the last two years, and in many cases one-fourth and one-sixteenth. This was a tenant-right, which certainly would hold out some inducement to invest money, but not to half the extent as a good long lease. He would ask them to look around, and see where was the tenant, holding his farm from year to year, and liable to be turned out at six months' notice, that could compete with his friend, the vice-chairman. (Hear, hear). He (Mr. Reader) would ask him personally whether his farm would have been so attractive as it was at the present time, had he not been holding under a lease? It might be all very well for people to talk of the confidence they had in this and that gentleman; but this he did object to, as it was not based on a sound and commercial principle; and, how had they seen that confidence abused within the last few years? He took, as an instance, the Duke of Northumberland. Not many years since his tenants thought they were safe; but the Duke offered a few prizes for good cultivation, &c., and, after getting his farms improved by his tenants, he, or his agent, with his sanction, drew up a lease, which the tenants were to sign or quit. He (Mr. Reader) thought it was admitted by all parties, who had the least knowledge of farming, that it was quite impossible for any person to follow the rules laid down, and the consequence was some of his best tenants left. He believe he was right in saying that one of the clauses gave the landlord or his steward the right to take possession of the land and all stock, &c., on the farm, to sell, and such like, and to deduct the rent, and what he thought proper besides, for any little deviation from the rules prescribed in the lease, and then hand over the remainder to the tenant. Mr. Reader then cited the case of another noble earl who offered prizes in a similar way, and where a tenant had spent in improving his farm, in about five years, no less

than £3,000, and who then received six months' notice to quit, and to leave behind him all the hard earnings of his life for the benefit of the landlord. This tenant, he believed he was right in saying, had on the farm, at the time of receiving notice to quit, some 700 tons of night-soil, collected from the different towns, and 300 tons of lime. Nor was this the only case where a tenant had been ejected from his holding under similar circumstances. There was a certain captain (his name we withhold) who received six months' notice to quit, after having improved the farm to a very great extent; but there was this difference in the two cases—that the latter laid no blame to his landlord, but on the steward, and would not condescend to ask the reason why he was to be ejected; whilst the former inquired the cause, but obtained no reply. Now they had no means of knowing why either of these tenants, who had proved themselves good farmers, and had added wealth to the county, but who were now obliged to leave all behind them, should be thus served. It might have been some little petty affair. It might have been something respecting those vermin, commonly known by the name of rabbits. And were not most of them subject to such annoyances, and often without the means of knowing what was reported to landlords by gamekeepers against tenants? He (the speaker) thought if there was one reason more than another which ought to urge tenants on to the necessity of having leases, it was the rabbit system generally adopted by landlords. (Hear, hear). He should certainly like to see what it costs the county in keeping up those feudal game-laws. Before he concluded, Mr. Reader begged to draw their attention to another point, and that was to the impoverished state of the pasture land in this county. What, he would ask, was the cause of it? It was simply this—it required a longer time to get a return on grass land than on arable; and this he believed to be the only cause why the grass land had not attracted the attention of the tenants generally. He would also ask them this question: Supposing they were to manure a piece of meadow land just after the hay-harvest (generally admitted to be the best time), and at Michaelmas receive six months' notice to quit, what benefit would they derive from the manure? None. This circumstance alone he thought quite sufficient to call on landlords to grant leases for the benefit of themselves, the tenants, and, above all, the labourer (applause).

Mr. RANDALL perfectly agreed with Mr. Reader in his observations as to the advantage of leases. Although they were quite satisfied that a great many tenants-at-will had gone on for a number of years, and that there had been a good feeling existing between them and their landlords, still he did not think there was any real security to a tenant, unless he were holding under a lease. It often happened that a tenant-at-will entered upon a farm, which might be in a very bad state of cultivation; he might lay out his cspital in improvements, subject to quitting at six months' notice; after expending much of his capital, there might be such a thing as the farm falling into other hands—there might be fresh stewards, and such like; therefore, unless there were security of some sort, he did not think any man justified in laying out his capital upon it.

Mr. SAUNDERS (the Vice-President) said, as allusion had been made to him by Mr. Reader, he begged to make one or two observations. He had told them that he (Mr. Saunders) had improved his land because he was holding it under a lease, otherwise he could never have brought his farm to the state of cultivation he had; but he must inform them this had not been done but at a very great expense. He did not approve of what was termed the "cut-and-go" system, where a man had a return for his money each succeeding year—they ought to work for their landlords as well as themselves. He had been spending a very considerable sum in manures, &c., during the last thirty years; therefore he thought that a man holding under a long lease was of public good, because he was employing a great deal of labour in the neighbourhood in which he resided, and he was also expending a considerable aum in manures, &c.; therefore he was, in fact, a national good. He (Mr. S.) considered the tenant-at-will system a very bad one, because a man must make his rent during the year he holds it, not knowing whether some one else might not soon have possession of it. No tenant of a yearly holding was justified in putting himself to a great expense, because his present landlord might die, and he knew not who might then have it In those cases it sometimes happened that the landlord might say, when the farm was looking well, "I do not want to lose you, but then I must have more money;" and perhaps, by having a notice to quit, this brought him and his family into difficulties. If ever they passed by a farm (generally speaking) that was badly cultivated, and made the inquiry of the tenant, "How is it you do not farm better?" the reply was, "I am only a yearly tenant, and I must do the best I can." Many had told them that the reason they could not do better arose from the circumstance of their being only yearly tenants. Although they advocated a lease upon a farm, very much depended upon the conditions of that lease whether a man could put that farm into a good state or not. He (the speaker) called a seven years' lease no lease at all, in fact he would rather be a yearly tenant in such a case; but if a tenant had a fourteen years' lease he could go to work, for his hands were not then so much tied. He did not think, however, that a landlord was justified in letting for a long lease to a man who takea a farm and puts nothing on it, such an one was not entitled to a lease. There ought to be an understanding between landlord and tenant that the lease should be an open one until within the last one or two years of its expiration, so that there might be sufficient time allowed the latter for recovering himself. He did not like the idea of being compelled to adhere to certain rules, that wheat must be sown one year, and turnips another, and so on; for his own. part he was holding under an agreement to sow how he liked until within the last two years of the expiration of the lease. Mr. Saunders then repeated his argument, that if they saw a farm badly managed, it generally turned out to be a yearly tenure. He then cited a case where a man had a farm in Hampshire, which was much stocked with rabbits and hares. The tenant gave notice that he should give it up at the expiration of his lease. The farm was offered to others, but no one appeared willing to take it, on account of its being so infested with rabbits, &c., and the consequence was the landlord was obliged to take it into his own hands. At length, however, some one came along and offered to take it, provided these vermin were only got rid of; and the landlord having consented, a great number of rabbits were destroyed. He (Mr. S.) would advise everyone to have the damage done by the rabbits taken into consideration in their agreement. If the landlord paid for it, it would be all very well. He should be sorry, however, to place any restriction upon the landlord, and he hoped that he should always be able to see his own have a good day's sport. As for rabbits, he called them no sport: they were nothing but vermin. In conclusion, he observed that if a man did not manage his farm well during the first lease, a second ought not to be granted him. No doubt there were a great many good landlords in this county to yearly tenants, but he thought a tenant of that description was not justified in farming "up to the mark," as if he held under a lease. If a man had a lease for 12 or 14 years the landlord ought to do many things towards improving the farm, and the tenant should be expected to do a great many more. He again urged the necessity of long leases.

After a few observations from Mr. Clarke, Mr. Reader, and others,

Mr. JACKSON said it so happened that he had rented one farm as a yearly tenant, and one he had held under a lease. The first he took was as a yearly tenant, and the farm was very much out of condition, for it had been very badly managed. However, he set to work to improve it; and after some few years he had the satisfaction of seeing it produce good crops; but he soon after had the misfortune of feeling the ill effects of the system alluded to by Mr. Reader. He found that although he was trying to produce good crops, he had those vermin (rabbits) come and eat them up. It was true, he had one of the best landlords he could possibly wish, but he had the misfortune of having some one to go between and make mischief; circumstances being misrepresented as regarded the damage done by the rabbits. Mr. Jackson then went on to say that he obtained leave to kill what rabbits and hares he thought proper, and an improvement soon took place. At length, however, he desired to leave the farm, but did not like leaving behind what he had put upon it. He therefore asked permission to choose a tenant to take the same off his hands: but the consequence was the rent was to be raised, on account of the improvements which had been made. The result of this was that he could not demand so much of the in-coming tenant

as he should wish. He then thought he was entitled to receive some compensation from the landlord for his outlay, and he kindly handed him a cheque on that account. If they could secure such landlords as that, they would not require long leases; but if he had died, what would have become of his farm? for here he had buried, as it were, his property in the soil. When he took the next farm he began to be a little wiser, and had it upon a lease. He took it upon the following terms—either for seven or fourteen years, to be at his option to leave at the end of seven if he felt inclined. After some further remarks, the speaker proceeded to say that he was very glad to find Mr. Reader had brought forward something on the rabbit system. He thought the farmers of England were very remiss in not coming forward in a body against it—he did not mean against the landlords. He had the honour of introducing the subject at an agricultural meeting some little time since, Sir E. B Lytton occupying the chair; and he was gratified to hear the tables ring, and the hands clap, when he spoke against the game laws. If, however, Mr. A. was running with the stream, and Mr. B. was rowing against it, one had better be out of the way altogether (Hear, and laughter). He did not say this for the purpose of setting the landlord and tenant at variance, for he wished them to go on hand in hand; but depend upon it as long as the gamekeeper stood between them, they would never get on (loud applause.)

After a few observations from Mr. READER, and others,

The CHAIRMAN having expressed himself in favour of the long lease system, offered a few remarks on the rabbit system, remarking that it was a subject between landlord and tenant; the matter ought to be laid before the landlord, who must be told that the rabbits are a nuisance. It was quite impossible to farm well when they had a lot of these about them. He then proposed a vote of thanks to Mr. Reader, for the able manner in which he had brought forward his subject.

Mr. FOWLER said there was one part of the subject he should like to notice, and that was with regard to the vast amount of waste land in certain parts which might be brought into a state of cultivation. It had occurred to him that if they had the advantage of a long lease, trouble might be taken to make it productive. Let them look at the heath-lands, for instance; but if they had not length of time given them, it was impossible to do anything with it. With regard to the inexhaustible improvements upon their farms, he did think that it would be of great advantage, both to the landlord and tenant, if compensation were allowed. He concluded by seconding the proposition of Mr. Damen.

Mr. READER, in returning thanks, referred to what had fallen from Mr. Fowler respecting the cultivation of waste lands, and observed that if, as he had shown them, such a thing could be done in Scotland under long leases, surely it might be done in this country—for what would apply to Scotland, would in some degree apply to England. He thought there was a great deal of waste land in this country that could be made to produce good crops, provided the system of long leases was adopted. He hoped he should live to see a different system in the holdings of land in this country than at the present time. He then moved the following resolution: "That this club would strongly recommend to the notice of the landholders and tenants the necessity there exists for improving the cultivation of the land, so as to develope its resources to its full extent, which cannot be carried out under the present tenure, more especially grass land. They would recommend leases of 21 years, determinable at the end of 14 years, by either party giving two years' notice; and at the expiration of the term a fair and equitable sum to be paid for unexhausted improvements."

The resolution having been carried unanimously, the proceedings terminated.

HADDINGTON AGRICULTURAL CLUB.

The monthly meeting of this Club was held in the George Inn, Haddington, on Friday, Jan. 8, Mr. Samuel Sheriff, Saltcoats, in the chair. There was a large attendance of members; and, after dinner and the usual loyal toasts, the subject before the meeting was, "Reports by Members of Experiments with Artificial Manures."

The CHAIRMAN said: Gentlemen, we are met this afternoon to hear "Reports of Experiments with Artificial Manures, by Members of this Club." You will recollect how, last spring, we came to discuss what were the "Best Substitutes for Guano." The continued rise in the price of guano compelled us to do this. The results of a few experiments made for this object I have now the pleasure to lay before you. But, gentlemen, will you bear with me while I introduce the subject by a few observations upon the marked change which has taken place within the last few years, both in the desire by agriculturists to give all the information in their power, also in the means of their doing so? Is it not a startling fact, gentlemen, when we think of it now, but a few years ago and we had no agricultural newspaper? All agricultural information was conveyed, and but sparingly, through the medium of the "Agricultural Journal of the Highland Society." Now, through the *N. B. Agriculturist*, we have a weekly record of the agricultural practice of Great Britain. What stimulus this gives to practical husbandry! One great feature of the age we live in is the desire for information; and this again is met by as great a desire to impart it. Some years ago, I remember (shortly after this Club was formed), we had a serious discussion whether our discussions and reports were to be given to the public. Were such a motion to be made now, what would become of it? It is by this system, and this system alone, that the proper cultivation of the soil is to be continued and increased, in order to keep pace with the rapid strides of advance made in every other science. Some very cautious men would argue, it does not do to tell too much. An invention in machinery is patented, and an immediate reward accrues to the inventor. Can you grow 14 bolls of wheat or 40 tons of turnips per acre, by following some system known only to yourself? Do so, and keep your secret. I would compare the man who would do so "to the servant who hid his talent in the earth." Cultivators of the soil have a heavy responsibility; besides having their own interests to look after, what countless thousands depend on them for the *substantial* necessaries of life! The more you can make the soil produce the better for the grower, and the greater the supply the better for the consumer. The only antidote to low-priced grain is to grow more of it, if possible; or by making an acre of turnips feed two cattle instead of one, you can afford to take a cheaper price per stone. Some years ago, when grain was considerably cheaper than at present, this doctrine was both preached and practised successfully. But the means at command were very different. We could procure the finest Peruvian guano at £9 per ton, nitrate of soda at £15, rapedust about £4 10s. Contrast the present prices of these articles. Why, in guano alone, the farmer using 30 tons, finds an extra charge of £180. Why are these things so? We have it in our power to resist extortion, simply by refusing for a time to use the article. Why have we frequently to take much less of a Friday for our grain? Just because the buyers refuse to give more. Look at the heavy fall which has taken place of late in the price of almost every marketable commodity—skins and hides especially. All this falls upon the farmer; and are they going to be so inconsiderate as to give the present high demand for guano? But this brings me to the subject now at issue. Before laying the results of the experiments before you, let me ask why you try experiments? Of course, you anticipate the answer, viz., for a two-fold reason—first, to ascertain what is really the most profitable stimulant to apply to vegetation; and secondly, to detect the weaknesses of the many fertilizers now offered to farmers. There is not a season without something new, and the best ever heard of has not been offered to us. We are asked by some one or other to try his patent improved quintessence of something or other; you are prevailed upon to try it, and find yourself minus £8 9s. without any benefit—sometimes a loss, because some safer and known stimulant wou d have secured a good crop.

TABLE No. 1.

EXPERIMENTS WITH SWEDISH TURNIPS.

Farmyard manure applied on the stubble, 30 loads to the acre Scots. Artificial manures applied in the drill at the rate of 5 cwt. per acre.

	Cost per acre.	*Yield.* tons. cwt.
No. 1. Mixture 2½ cwt. guano and 2½ cwt. B. manure, at 11s. 6d.	£2 17 6	22 14
No. 2. 5 cwt. Dall's manure, at 9s. ..	2 5 0	19 10
No. 3. 5 cwt. Peruvian guano, at 14s. 6d.....	3 12 6	23 6
No. 4. 5 cwt. B. manure, at 8s. 6d...	2 2 6	21 5
No. 5. same application as No. 1, but different seed, at 11s. 6d.....	2 17 6	15 13

Comparative Results of the above.

Guano, No. 3, gives 12 cwt. of swedes more than No. 1, but at a cost of 15s.

No. 3 gives 2 tons 1 cwt. more than No. 4, but at a cost of £1 10s.

No. 3 gives 3 tons 16 cwt. more than No. 2, at a cost of £1 7s. 6d.

No. 5, Different seed, 7 tons 13 cwt.

TABLE No. 2.

EXPERIMENTS WITH WHITE GLOBE.

No manure to stubble.

		tons. cwt.
No. 1. 8 cwt. per acre superphosphate, at 8s.	£3 4 0	9 0
No. 2. 8 cwt. guano, Peruvian, at 12s. 6d.	5 0 0	12 12
No. 3. 8 cwt. B. manure, at 8s. 6d...	3 8 0	10 4
No. 4. 8 cwt. Indian guano, at 8s....	3 4 0	10 16
No. 5. Mixture, 5 cwt. bones and 3 cwt. guano, at 10s. 6d.	4 4 0	12 0

Comparative Results of the above.

No. 2, Guano, gives 3 tons 12 cwt. more than No. 1, at a cost of £1 16s.

No. 2, Guano, gives 2 tons 8 cwt. more than No. 3, at a cost of £1 12s.

No. 2, Guano, gives 1 ton 16 cwt. more than No. 4, at a cost of £1 16s.

No. 2, Guano, gives 12 cwt. per acre more than No. 5, at a cost of 16s.

TABLE No. 3.

EXPERIMENTS WITH PURPLE TOP.

		tons. cwt.
No. 1. Mixture, 10 cwt. drill bones and 5 cwt. rape, at 6s. 3d. per cwt.	£4 13 9	14 8
No. 2. Mixture, 3 cwt. guano, Peruvian, and 5 cwt. superphosphate, at 10s. 6d. per cwt.....	4 4 0	16 4

Comparative Results.

No. 2, gives 1 ton 16 cwt. more than No. 1, costing 9s. 9d. less.

Well, gentlemen, the results of the experiments which I now lay before you, go to prove that guano is the greatest fertilizer we possess; but when you come to count the *cost*, it is not the most profitable at its present price—at least, from an analysis of my experiments. You will observe that the extra quantity of turnips raised from guano cost the owner too much. The striking feature in the experiment No. 5 of Table 1, shows how important it is to secure the best variety of seed. Why, here is an actual difference of 7 tons 13 cwt. where the same manures were applied. But this is a subject for another discussion. I would detain you too long were I to enlarge on this theme. I now refer you to Table No. 2. The small crop will startle you all. This I attribute entirely to accident. The first braird was completely burnt up by the hot sun we had for some days during the latter part of June and beginning of July. I had to re-sow the field, with the exception of a small portion, where I had the experiment between rape and drill bones against guano and superphosphate. They suffered also from the hot sun. The soil is almost pure sand. Gentlemen, I hesitated whether or not to tell of this small crop. Are we not too proud often to speak of our large crops, and keep the small ones to ourselves? I would call your attention particularly to the fact of this new guano; Indian guano, at £8 per ton, having grown a larger crop than superphosphate. I would refer you to an experiment made in Roxburghshire, where, when mixed with Peruvian, it gives a greater return than Peruvian alone. This is a fact well worthy of notice. I was rather surprised with the result of the experiments with purple-top turnips. The mixture of guano and dissolved bones brairded sooner, and were ready for singling some days before the other; but during autumn the contrast was most marked—the leaves of the rape and drill bones' experiment continued green long after the other had withered: but the earlier turnips this season were by far the best crop, and in eight seasons out of ten we will find this to be the case. But I fear I trespass too long, when I consider the other reports to be brought before you, while, I cannot close without expressing a hope that we may really, and in earnest, try to resist the high price asked for *guano*. This is a season of great commercial depression. It is felt by all. May the cloud which now hangs over us soon disappear. I am sure all who deal in the artificial manures most in vogue must know that the greater the quantity sold, even at a small profit, is best for themselves. I would close my observations with one remark on the difficulty of arriving at correct conclusions, unless experiments are repeated. This county stands pre-eminent for its agriculture. Let it not be behind others in its endeavours to impart additional information. I may mention that the measurements, weighing, &c., of my experiments were conducted under the eye of Mr. Patrick Sheriff, whose qualifications for this are known to you all.

Mr. HOPE, Fenton Barns, said: He had listened with much interest to the excellent paper which the Chairman had just read. The experiments appeared to have been carefully conducted, and the results accurately ascertained. There was, however, something very singular attending the turnip crop this year. Some fields were remarkably fine, and others very inferior. A difference in a single day in the sowing made a difference of tons per acre in the crop, while an over-luxuriance in leaves in many cases diminished the size of the bulbs. Guano had not this year with him maintained its wonted superiority; perhaps they had been applying it too liberally for some time past, and manures richer in phosphates might be found more profitable. He had tried Cant's manure, which had been supplied to him by Mr. Peacock, of Edinburgh, in growing swedes. The land was well manured with farm-yard dung on the stubble in autumn. He gave 7½ cwt. of Cant's manure, and 8 bushels bone-dust in the drills. Adjoining, he gave 5 cwts. Peruvian guano and 8 bushels bone-dust, all per Scotch acre. The guano had much the strongest leaves throughout the season, and, when he went to weigh the crop, he thought the difference in favour of the guano would be 2 or 3 tons per acre; but it turned out only 12 cwt. and some lbs. He had also sown a ton of manure which he got from Mr. Dall, North Berwick. He applied 8 cwt. per Scotch acre, along with about 20 carts dung in the drills, as against 5 cwt. guano and 8 bushels bones. The crop was purple-top yellow, and Mr. Dall's manure produced the heaviest crop by 10 cwt., though neither was so heavy as he expected. From these results, and the high price of guano, he was resolved to use less guano and more of bones and other manures containing a greater proportion of phosphates.

Mr. David Sheriff, Muirton, gave the following report of the experiments made by him at Muirton for crop 1857:—

EXPERIMENTS MADE UPON MUIRTON FARM—CROP 1857.

This season I made a trial of six different lots of white turnips, of three drills each, sown about the 15th of May, 1857; manured at the expense of £5 12s. per Scotch acre. The result was as follows:—

	tons.	cwts.
Guano	34	16
Dissolved bones	26	9
B. manure	29	0
Rape dust	30	9
Blood manure	29	0
Manning's patent	29	0

I made another trial also this season, with guano against Manning's patent manure. The land was dunged in winter at the rate of 28 carts of home dung per Scotch acre, and at sowing 210lbs. of guano against 5 cwt. of Manning's patent manure. The turnips were sown on the 4th of June, 1857,

and weighed on the 11th of December last. The result was as follows:—

	tons.	cwt.	st.	lb.
Guano and manure—				
Green top white	27	18	0	0
Purple top	21	11	1	2
Manning and manure—				
Green top	27	0	6	12
Purple top	19	1	3	6

Money value of each of the manures, £1 6s. 3d.

Mr. Robert Scot Skirving, Campton; Mr. Durie, Standingstane; Mr. Cunningham, guano merchant, Edinburgh, and other members, took part in the discussion; and a committee, consisting of Mr. George Hope, Mr. Sydserff, Ruchlaw; Mr Robert Scott Skirving, Mr. Samuel Sheriff, and Mr. David Sheriff, was appointed to frame rules for members conducting experiments in raising turnips with the different manures—the results to be reported to the meeting of the Club in January, 1859.—*North British Agriculturist.*

MANURE WITHIN REACH OF THE FARMER.

Sir,—"Let nothing be lost," was the command of our divine Lord and Master to his disciples many centuries ago; and although, since these ages have elapsed, laws have altered and customs changed, the force of the axiom still remains unimpaired, and whether with reference to the warnings we may receive, the opportunities afforded us, or the advantages placed within our reach, it forms the basis of all success and prosperity in every undertaking: "Let *nothing* be lost." In applying this maxim to the collecting of manure, it might not be out of place to bear in mind the Scotch adage, "A stone is the only mote in a muck-heap"; but a more extended knowledge of things has taught us that what have long been considered stones are even to be made valuable as a manure. Almost every thing, therefore, is worthy of our attention in this respect, and is in some way or other to be rendered available in aiding fertilization.

In days when agriculture was much more imperfectly understood than at present, great carelessness was exhibited with regard to manure. Much valuable material was burnt, liquid manure allowed to run waste, and even the excrements of the stock with the straw lay exposed to evaporation, under a burning sun, and to waste by fermentation. I would be glad if in our day, and under the authority of an enlightened state of agriculture, no such abuses existed. But alas! I am sorry to be forced to acknowledge that men with their eyes open should still be equally neglectful of these important elements of successful agriculture, annually spending large sums upon artificial manures (many of which are altogether useless), and neglecting to take advantage of those valuable fertilizers produced upon their own farms, which require only care, attention, and a small outlay, to be rendered available.

The soil is to be considered as the great store-house, to contain the food of plants, and the medium operated upon by air, water, and heat, which, by their various actions upon the soil and the manure which it contains, transforms certain of their constituents into such a soluble and gaseous state as to be absorbed by the spongioles of the roots, and enter into the organization of the plant; so that it is by the application of the proper manures to the proper crop, and in such quantities as to meet the requirements of the soil, that the result in the crop, in ordinary cases, is to be attributed to the different descriptions of soil affecting this more particularly by their tendency to retain moisture or the contrary, their liability to become over-saturated, their power of attracting heat, or their readiness to become impregnated with those gases assimilated by the plants; so that the value of soils is not entirely dependent upon the amount of the food of plants which they naturally contain, but by the manner in which they (according to their nature) allow the food supplied in the manure to be assimilated by the plants, and yield to them the greatest benefit of which it is capable.

Having thus briefly adverted to the action of manure in the soil and its assimilation by plants, with the view of illustrating how necessary it is for every farmer to bestow the greatest attention upon the care and management of his manures, let me now turn more particularly to the object of my letter; and first reflect upon that custom so prevalent in all parts of the country of burning couch-grass and all vegetable rubbish collected upon the farm, a practice which I consider most wasteful and impolitic. By analysis we learn that throughout the vegetable kingdom there exists a great similarity in the constitution of plants, their components being almost the same, but existing in different proportions in different kinds of plants; surely, then, it is reasonable to conclude that there must be contained in all vegetable matter much that is valuable as the food of plants, and requiring only to be brought into such a condition as to be assimilated by them. No doubt combustion is a sure means of destroying the vitality of all seeds and weeds of every description; but it is an equally certain mode of dissipating mucilaginous, gelatinous, saccharine, oily, and extractive fluids, which along with solution of carbonic acid and water are substances, which in their unchanged state contain almost all the principles necessary for the life of plants. The substances, therefore, which principally compose vegetable matter are dissipated by the action of fire; and thus, by the loss of those very ingredients which constitute their chief value as a manure, they become reduced to a mere fraction of their original bulk.

Upon retentive soils, burnt earth or calcined clay may have a very good effect; but in this case their action (particularly the latter) is almost entirely mechanical, by disintegrating the soil—their value as a manure consisting chiefly in the amount of carbon, and its power of absorbing ammonia from the atmosphere. Paring and burning, although perhaps judicious in reclaiming certain lands in which all kinds of troublesome seeds, roots, grubs, and larvæ of insects abound, still in very many instances in which it is adopted it must be pronounced a wasteful practice; but whilst benefit may result from the application of fire in the instances above-mentioned, we know of no pretext whatever, beyond that of custom, for the burning of couch-grass and other vegetable refuse. Experiments have proved that the ashes of burnt straw are an excellent manure, but who would think of consuming his straw by fire! And yet as regards manure, this would be more excusable than the combustion of vegetable matter, inasmuch as the constituents of straw have become more solidified, and require more powerful means to effect decomposition than succulent vegetable matter, and also far less valuable, much of its quality being lost in ripening the grain. In ploughing in succulent vegetables for manure, of course decomposition immediately takes place without any preparation, and, with almost every description, a very slight incipient fermentation is only necessary to commence decay of the woody fibre; in fact, to allow any manure to ferment to a great degree is highly prejudicial to the interests of the farmer. Sir H. Davy even doubts whether *straw* would not be more beneficial as a manure if chopped up

and applied in a dry state, rather than lose much of its value by fermentation; but we are now too well acquainted with the value of straw as an absorbent, &c., to be enabled to apply it in such a manner. To destroy the vitality of couch-grass or such-like weeds, the application of quick-lime, salt, or vitriol with a degree of fermentation is necessary. But where fermentation is going on in a dunghill, it is of great advantage to cover it with burnt earth to absorb the disengaged gases; or, if burnt earth cannot be had, then common salt with gypsum will have a good effect.

And now, sir, will you allow me to say a word to brother farmers upon liquid manure: I mean that produced in the farm-yard. Much has already been said and written upon the subject. I will not, therefore, be tedious, nor stop to notice all the different plans that have been tried and recommended for its use. Still, I see numerous instances of its being neglected. Why should this be? It is the very essence of your manure. Try to prevent its being over-diluted with water by troughing your buildings, &c., although a *little* water mixed with it is advantageous when applied in a liquid state; but get your muck-heaps to absorb as much of it as you can. Apply it also in abundance to the earth you have carted for bottoms to your muck-heaps, and, if well saturated, they will be valuable, although not mixed with muck at all. Convert it into solid as much as possible: by this means you prolong its action in the soil. But, when you do apply it in a liquid state, it has a good effect upon grass-land of every description; and, from the amount of its ammoniacal qualities, I have found it very beneficial to corn-crops whenever applied upon the land before ploughed up for sowing. Urine contains the essential elements of vegetables in a state of solution, and consequently in a state of the utmost possible preparedness, and is eminently suited to all crops which require speedy and large ailmenting with such saline and organic principles as it contains; but in a liquid state its operation is quick, but not durable.

I will now conclude with a few remarks upon other two descriptions of manure within reach of the farmer, and which well deserve attention, viz., the manure from the fowls' house and ashes from the fires. These are too valuable to be mixed with the farm-yard manure, they can be applied by themselves with much greater advantage. It has been computed that fowls' dung, weight for weight, is half as valuable as Peruvian guano, and that no description of manure is more deteriorated by decomposition; to prevent which, it ought to remain untouched until required for use, and gypsum or powdered charcoal sprinkled over it once a week, to prevent the escape of the ammonia. But without further remark, I will briefly describe a method of applying fowls' dung and ashes, which I have seen practised for many years with eminent success. The ashes throughout the year are collected in a heap, and with them a quantity of rich mould mixed; this is saturated with liquid manure from the tank as often as it requires. A week or two before turnip-sowing, the manure from the fowl's house is brought, also a small quantity of ground bones. These are all mixed together, and twice turned over, and incipient fermentation allowed to commence. It is then taken to the field; shallow ridges are formed, in the bottom of which the manure is planted in small handfuls from 9 to 12 inches apart, at the rate of 1½ to 2 tons an acre, according to the richness of the compost. This is performed by women with baskets. The seed is then sown with a machine along the ridges, after the manure has been lightly covered with a plough. So eminently is this adapted for turnips, that I never recollect seeing it fail—always producing a crop superior to any other plan, and even showing good effects upon the succeeding crop of barley.

I am afraid, Mr. Editor, I have trespassed too far upon your valuable space; I hope, however, the importance of the subject (however imperfectly treated) will be a sufficient apology for my intrusion. For although many farmers are very careful to turn everything to advantage, there are numerous others who—although readily admitting the necessity and propriety of so doing—are nevertheless very careless and indifferent in the performance of it. And if from a deficiency of chemical knowledge I have committed mistakes in the course of my remarks, still I think the accuracy of the principles I have attempted to lay down cannot be doubted—viz., that plenty of manure is a most essential element in good farming; that the care and management of manures produced upon the farm are much neglected; that the burning of vegetable matter is wasteful; that by allowing fermentation to go too far much loss is sustained; that liquid manure is of great value; and that fowls' dung and ashes deserve special attention: in short, that almost everything quite valueless in other respects is of value as muck; and that it behoves every farmer to turn to the greatest advantage the supply of manure produced upon his own farm before purchasing at the expensive and deceptive mart of the manufacturer and importer. And no watchword will prove a surer guide to the accomplishment of this object than that with which we introduced this subject—"Let nothing be lost."

WM. ARNOTT.

Melton, Woodbridge, Suffolk, Jan. 13.

ON THE METHOD OF EXTRACTING THE STARCH FROM THE POTATO.

The operations for this purpose are as follows:

1st, Washing the tubers.
2nd, Reducing them to a pulp, by rasping.
3rd, Pressing the pulp.
4th, Washing the rough starch.
5th, Draining and drying the produce.
6th, Bolting and storing.

1st. The washing of the tubers requires particular attention, any dirt left on them being injurious to the purity of the starch. The water itself ought to be perfectly pure and clear. An open cylinder, working in a trough, into which a stream of water can be constantly pouring, is the best method of effecting it.

2nd. The rasping is accomplished by cylinders made of sheet-iron, roughed by having holes thickly punched in it from the inside, so as to form a grater. Or, if a more expensive and durable machine is required, the cylinder is furnished with iron cutters, set in wood. This is placed under a hopper similar to that of a corn-mill. The cutting cylinder is made to turn rapidly—say from 600 to 900 times per minute; but the quicker this is done, the more effectual will be the separation of the starch, &c., in the tubers. The cylinder should be about 16 inches long, and 20 inches in diameter; and such a one, revolving by means of multiplying wheels 800 times per minute, will reduce 50 bushels of potatoes per hour to a perfect pulp. It may be worked either by water, steam, horse, or hand-power.

3rd. The pulping being effected, it is passed through a wire sieve; and the cellular tissues, which constitute the

coarser parts, are separated, and must be pressed, to extract from it what starch still remains.

4th. Water is poured on the pulp whilst passing through the sieve. This is run into vats, in which it is allowed to settle. When quite clear, the water is poured off, and a fresh supply put on.

5th. When the starch is perfectly clean, the water is finally poured off, and the starch taken out, and laid on a perfectly clean floor, where it soon becomes hardened and consolidated into a firm cake, or mass.

The sixth process finishes the operation, by breaking up the mass into flour, and passing it through a bolting machine like those in a flour-mill, which prepares it for sale.

Any machinist is competent to fit up the necessary apparatus, either upon a large or small, cheap or expensive scale. No grower of potatoes to any considerable extent ought to be without this addition to his agricultural implements or machinery, especially in those parts of the country where it is difficult to dispose of a crop of unsound potatoes, and it may not be convenient to consume them by cattle or pigs. In such cases, the diseased tubers are scarcely worth the raising; and we have this season heard of instances in which the growers will not go to the expense of raising them. The money produce of manufacturing the potatoes may be stated as follows:

	£	s.	d.
1 ton of potatoes, or 2,240lb., produces, at 17 per cent., 3 cwt. 1 qr. 16lb. of starch, at £22 per ton	3	15	0
1 cwt. of residue	0	11	0
	£4	6	0

Against this must be charged the expense of manufacture, and the wear-and-tear of machinery, neither of which is at all costly, as they require neither skilled labour nor complicated machines.

Were it not for the excise, the starch, when extracted, might easily be converted into sugar by a chemical process, every cwt. of starch (112lb.) producing 140lb. of sugar. The process, however, is both complicated and expensive, and would only be remunerative upon a large scale, which is not the case with the manufacture of starch, which may be performed by women in even a less expensive mode (on a small scale) than the one we have described.

EXTRACTION OF FOOD AND STARCH FROM THE POTATO.

Sir,—I have read with great pleasure your observations respecting the extraction of starch from the potato; and as I have had much experience in the matter, having been, I believe, the first to introduce the manufacture into this country, as far back as the year 1830, I would beg to offer my testimony in favour of all you have stated, and strongly recommend to farmers the conversion of the potato not only into starch, but into food, which could be simply accomplished, even with the appliances which almost every farmer now possesses.

The paper which I send you—the *Irish Farmers' Journal*, of the 27th of May, 1846—gives a description of what was then put into practice at the South Dublin Union by the paupers, in producing food from diseased potatoes; and the facts are, I conceive, of paramount interest to every farmer.

Strange to say, the whole has lain dormant since that time, notwithstanding that not one word of what is set forth can be denied. It is incontrovertible that the actual nutritive value of food for man, to be had from the potato, is nearly four times that to be had from wheat, when the produce of each is taken from an equal extent of land. In other words, an acre of land cultivated with wheat will produce an average of—starch, sugar, gluten, and oil—1,055 lbs., whilst an acre of potatoes will produce, of the same, 4,076 lbs., each constituent being in nearly equal proportion.

Should you think right to insert this communication and the paper I send, I shall at another time put before your readers simple directions for the *modus operandi*; and some facts which may perhaps explain why so singularly advantageous a process, as well for the farmer as the public, has been suffered to rest unproductive.

I have the honour to be, sir, your obedient servant.

Jasper W. Rogers.

Peat House, Robertstown, Co. Kildare,
Dec. 27, 1857.

ARTIFICIAL PREPARATIONS FROM THE POTATO.

There is no other of our agricultural plants which have come in alternately for so great a share of eulogy and abuse as the potato. On one hand we hear of its being one of the best of Nature's gifts; and on the other, that to its general cultivation in this country we may ascribe most of the misery of its inhabitants. Notwithstanding all the discussion which has taken place on the subject, it is surprising that the real value of the potato should be so little understood. In its ordinary form it is one of the most perishable articles of food which we possess; but it is capable of being rendered, by artificial means of an extremely simple character, not only portable, but capable of being preserved for an almost indefinite period. There is, in fact, scarcely any other vegetable production capable of being made to assume so many forms or of being turned to account in so many different ways; but although this property has been long known to scientific men, it is surprising how little way has hitherto been made in putting the lower classes, who are forced to exist almost exclusively on a potato diet, in possession of this information.

The disease which made such ravages among the potato crop of last season has caused attention to be forcibly directed to these facts, and the conversion of the decaying portion of the crop into farina was a favourite project. It being known that the attention of Government was directed to the matter, numerous statements on the subject were placed before his Excellency; and among others one from Mr. Jasper W. Rogers, C.E., who had more than ordinary experience. That gentleman's plan was considered so very satisfactory that his Excellency the Lord-Lieutenant at once gave directions that facilities should be granted for having it fairly tested. Some of the results of Mr. Rogers' method of making the potato available as food, in many different forms, were exhibited on Saturday last, in the Board-room of the South Dublin Union Workhouse, before the Guardians and a number of other influential and scientific persons in the form of an elegant *dejeuner*, all the items of which, with the exception of coffee, were prepared more or less from the potato; when a most satisfactory account was afforded by Mr. Rogers, of the different processes in their preparation, with much interesting information relative to the value of the potato itself, which, he very justly observed, is too much overlooked. Every one present was astonished at the rich treat provided on the occasion, which consisted of soup, stirabout, milk porridge, jellies, blancmange, Spanish flummery, and pastry of all kinds, made, as we have already stated, principally of the produce of the potato, either as meal, flour, or fecula.

After the gentlemen present had partaken of the various preparations, Mr. Rogers observed that the preparation of the meal and flour from potatoes was so simple that it could be accomplished in the cottage of the poorest peasant. He then described the component parts of each food upon the table. The general proportion being one-half potatoes; some, however—viz., milk porridge, "Scotch bread," and

rock biscuits—being entirely made from it; also the jellies, blanc-mange, &c., produced from the *pure fecula*, without animal matter of any kind—in fact, no addition but the usual seasonings. The soup, also, which appeared to be a palatable and nutritious food for the lower classes, was stated to be made of a small quantity of bacon, thickened with the meal of the potato, and which was capable of being made in a short period of time at a cost of about one farthing per pint.

Mr. Rogers then alluded to the general impression as to the want of nutritive power in the potato, and deprecated the publication of statements which were founded in error, stating that there was "little, if any, nutriment in the potato." He contended that the nutritive properties of the meal and flour of potatoes were almost, if not entirely, equal to that of wheat; and then gave the following analyses of each, assuming the constituents, for the support of animal life, contained in vegetables, to be starch, sugar, and gluten.

When converted into meal, the potato contains—

Starch and sugar	84·08
Gluten	14·82
Oil	1·10
	100·

While wheat, converted into meal, contained—

Starch and sugar	78·20
Gluten	17·53
Oil	4·27
	100·

Thus showing that the difference between the gluten was but 2¾ per cent., while the starch and sugar were more abundant.

The difference between "meal and flour of potato," prepared as recommended, and "farina," was pointed out. Farina is the starch of the potato, taken from the fibre, and contains nothing beyond the properties of starch; while the fibre, which is thrown away in the manufacture of farina, is rich in animal matter and oil, and by being combined with the farina or fecula, produces a meal or flour closely analogous to that of grain. This fact it was particularly necessary to bear in mind, in order to counteract the impression that there was but little nutriment in potatoes—a strange one, where so many millions lived on them as their only food.

A comparison was then entered into between the relative amount of food obtained from an acre of land in wheat and potatoes. On this subject, Mr. Rogers stated that he did not rely on his own experience, but cited the authority of practical men as to produce, and of eminent scientific men, as to the analysis of the respective crops, stating the following as the result of his inquiry:—

	Starch & Sugar.	Gluten.	Oil.
1 acre of Wheat	825 lbs.	135 lbs.	45 lbs.
1 acre of Potatoes ..	3427 lbs.	604 lbs.	45 lbs.

Thus it appears that potatoes will produce of meal and flour, FOUR TIMES, nearly, in weight, what can be had from wheat—a fact not generally known, but which could not be contradicted. He begged to impress this startling fact on the minds of those who heard him, and hoped to rescue the potato from the calumnies thrown upon it. In an establishment, such as the South Dublin Union Workhouse, containing from 1,800 to 2,000 persons, Mr. Rogers stated, that from fifty to sixty paupers would be able to prepare of potato meal and flour, by the simple means in operation, a sufficiency—say, four to five tons per week—for the use of the house, mixed with other meal, by which a saving would be made in the expenditure of the establishment of above £1,500 a year. He sat down midst much applause.

Sir Robert Shaw, Bart., who presided on the occasion, expressed his astonishment at what he had seen, and at the statements made by Mr. Rogers, as to the nutritive properties of the potato, compared with those of corn, which differed greatly from the impression which had been hitherto on his mind, on the subject. He would have supposed it impossible to put the potato into so many different forms as they had before them. They all owed great obligations to Mr. Rogers for the handsome manner in which that entertainment had been put before them, and in the name of the Guardians, he (the chairman) returned him thanks. He had brought most valuable information before them, which would be of great use if disseminated through the country.

Mr. Rogers returned thanks, and in doing so, observed that his great object was to render the manufacture of the potato general, henceforward, throughout the country—not alone for workhouses and jails, but that every poor cottier might be enabled to have his bread, his stirabout, and his soup, as well as his boiled potato—which could be done by teaching the people a most simple process, capable of being carried on in every cottage in the country.

Considering the large and influential body of gentlemen before whom Mr. Rogers so successfully exhibited the good account to which our much-abused vegetable may be turned, it is to be hoped that some of them, at least, will further test the advantages which he held forth. No better expedient could have been adopted for showing the value of the potato, in a way not likely to be forgotten; and it must be remembered that although it was extraordinary circumstances which caused the matter to be brought so forcibly under public notice, yet, under ordinary circumstances, it cannot be questioned that a portion of the crop may be converted into meal with great advantage, and be made the means of adding largely to the comforts of our peasantry.—*Irish Farmers' Journal*, May, 1846.

TITHE COMMUTATION.

SIR,—As many of your readers may feel anxious to know the result of the corn average for the seven years to Christmas last, published by authority in the *London Gazette* of the 8th inst., viz.—

Wheat	7s.	2¾d. per imperial bushel.
Barley	4s.	3½d. „ „
Oats.....	2s.	11d. „ „

I beg to state, for their information, that each £100 of tithe rent-charge will, for the year 1858, amount to £105 16s. 3½d., which is a little more than 6 per cent. above the last year's value.

The following statement, from my forthcoming "Annual Tithe Commutation Tables," will show the worth of £100 of tithe rent-charge for each year since the passing of the Tithe Commutation Act, viz.:—For the year

	£	s.	d.
1837	98	13	9¾
1838	97	7	11
1839	95	7	9
1840	98	15	9½
1841	102	12	5¼
1842	105	8	2¾
1843	105	12	2¼
1844	104	3	5¼
1845	103	17	11½
1846	102	17	8¾
1847	99	18	10¼
1848	102	1	0
1849	100	3	7¾
1850	98	16	10
1851	96	11	4¾
1852	93	16	11¼
1853	91	13	5¾
1854	90	19	5
1855	89	15	8¾
1856	93	18	1¼
1857	99	13	7¼
1858	105	16	3½
22)	£2,178	2	6¼
General average for 22 years ..	£99	0	1¼

I am, sir, your most obedient servant,

CHARLES M. WILLICH,
Actuary University Life Assurance Society.

25, Suffolk-street, Pall-Mall, Jan. 9.

THE DIFFERENT SYSTEMS OF DRAINAGE.

We are sometimes told that farmers ought to leave their habits and prejudices at home, and come to the discussion of an agricultural subject, exactly as a lobster would if divested of its shell. Let us see how much a meeting conducted on such terms would be worth. The cultivation of a dark, strong, homogeneous clay, affected entirely by water on its way from the heavens downwards to the sea, and where the principle has been to remove this as quickly as could be effected by open parallel furrows on the surface, a few feet distance only apart, and intersected by parallel open drains, in a cross direction, some 20 or 30 yards asunder. Such a system with one man is the only drainage that he requires to effect his object.

The cultivator from another district (probably the oolitic), where the soil is a dark tenacious clay at top, and an open, porous, or absorbent soil below, is satisfied with any depth of drain, provided it is deep enough to penetrate the retentive soil lying above, so as to give the water free admission to the porous subsoil below. Another, who lives in a district of greatly undulating surface—with a porous subsoil on extensive or dislocated portions, and intersected at all angles with beds of tenacious clay lying at various depths and thickness—the porous portion supplied and overcharged with water, endeavouring, by its own gravity, to force its way through it from the highest to the lowest level, and constantly endeavouring to escape upwards from its disposition to find a level, or rising to the surface by capillary attraction whenever the disintegrated particles rest on quicksands below, already highly charged with water—the resident in such a district says that nothing but *deep*-draining will answer, the *distance* apart being only secondary; but nothing less than four-feet drains, and in many instances even twice that depth, will suffice to rid the subsoil of its injurious occupant.

Again, we have the farmer from a country where one uniform flat surface prevails, and regularity of subsoil, are each of themselves equally remarkable features; and he requires drains as near to each other, in point of distance, as can be effected—6 yards apart at most, and from 26 to 36 inches in depth, running parallel to each other throughout the whole field. This mode he has found to answer his purpose, and he has no doubt will equally answer for everyone else.

And thus might we multiply instances without end. But as a few invariable and unerring principles are connected with the subject, we will endeavour to record them.

1st. The specific gravity of water is 817 times heavier than air.

2nd. By its gravity it always has a disposition to descend; but the instant it meets with resistance it exerts its force equally in every other direction.

3rd. That force is invariably exerted until it has found a level, and it can then only be said to be at rest.

4th. That whenever this equilibrium is attained, it remains in that state (stagnant) until disturbed.

5th. That in perforating the soil with a drain, that portion nearest the drain is first set in motion, and this is followed in successive rotation by the next nearest portion, and so on to the extent of its action.

6th. That its action ceases wherever the compactness of the soil is sufficient to overcome the gravity of the water held in it by suspension.

6th. That water not only descends by its specific gravity, but ascends by capillary action; wherever the lower portion of the soil rests in water, the complete disintegration of its particles facilitate that object.

7th. That water passing from a higher to a lower level through the soil, always has a tendency to rise to the surface, and would invariably do so unless intercepted by open or underground drains—hence the origin of springs.

8th. Water, on reaching the surface of the earth, would continue to descend in the soil until resisted, which it invariably would be whenever a porous soil was preceded by a retentive one.

9th. That water in its purest state, as rain water, is slightly charged with ammonia; but to an inconsiderable extent, excepting after long seasons of drought.

10th. That water becoming stagnant in a soil, becomes deleterious to plants growing upon the surface, the mineral deposits, especially iron, after entering into its composition, rising towards the surface.

11th. That water passing through a hollow pipe meets with resistance produced by friction. A pipe filled at one end cannot be made to run full at the other.

12th. That water in a drain, upon meeting with resistance, will fill it continuously upwards until the weight of the column of water overcomes such resistance by the pipes giving way at the lowest point.

13th. That the velocity with which drains discharge themselves depends upon their inclination and the permeability of the soil.

14th. The specific gravity of water being greater than that of air, it invariably displaces the latter in the soil; but upon its removal, air again occupies the space originally held by it, and thus a continuous action is produced in the soil.

15th. Water when frozen expands, and thus, by its power, the hardest substances become broken up, or have their external surfaces abraded by its action.

The foregoing is merely a statement of those principles which will ever be coming into operation during the processes of draining; and by observing which the operator can seldom err. Of all scientific practices, that of draining is of itself the simplest of application; the merely perforating the subsoil with a hollow drain, at a sufficient depth must necessarily draw off the accumulation of water held in suspension in the adjacent soil. If this be tenacious, from thirty to thirty-six inches, in most cases, will be sufficient, keeping in mind that, although a greater depth might be desirable, the cost of the drainage ought always to govern the proceeding. On the contrary, if the subsoil is porous and charged with water, flowing from a higher level, then the drains must be sufficiently deep to carry off the water, that the soil near the surface may not be rendered wet by capillary action, bearing in mind that the more complete and minute the disintegration of the soil, the greater the disposition of the water from below to ascend towards the surface. In some cases drains from forty to fifty inches will be requisite.

In soils alternating in quick succession of beds of gravel, sand, and clay, a few deep drains judiciously placed will generally effect the drainage of large portions of a field, remembering that the drain should always be cut so as to intercept the water passing in

the gravel or sand before it reaches the clay, and in a parallel direction with the edge of the deposit. In some cases the merely perforating the clay in one continuous line from one gravel bed to another to the lowest level will also equally well effect the object. The drains must invariably be deep enough to release the gravel altogether, and a previous knowledge of their extent and situation ought to be ascertained. No other description of draining is so difficult to perform as this, or when done, repays so largely for the operation. We might go on multiplying precedents *ad infinitum;* but it is not our intention to raise discussion, so much as to point out general principles to obviate it.

Water is the source of sustentation of the animal and vegetable kingdoms. The agriculturist, more especially than all others, becomes subjected to its influence. The smallest quantity, either in excess or deficiency, is to him severe injury or proportionate gain. If, therefore, we have cleared away any of the impediments by which its withdrawal can be effected, we have not toiled entirely in vain, even if we only succeed in obtaining attention.

REGENERATION OF THE POTATO BY CUTTINGS.

[TRANSLATED FROM THE FRENCH OF THE "JOURNAL D'AGRICULTURE PRATIQUE."]

The *Agricultural Chronicle*, of the first fortnight in December, has in a spirited manner exposed both the precipitous haste of the searchers after the philosopher's stone, and the emptiness of those brilliant panaceæ which are produced on all sides as soon as a question of a somewhat serious character has been brought before the public. But all this noise quickly subsides when the cause which has occasioned it is removed, and we trouble ourselves as little about it afterwards as before. We knew of no means of preventing it, and submitted to it with every symptom of impatience; but we do not take into account the possibility of its return. What an agitation was caused on the occasion of the potato disease, of the scourge that attacked the vine, of the disease which was announced in the beetroot! Is there any other produce which is not justly entitled to solve this important problem—"*Life at a cheap rate*"? But how prompt are all voices, erewhile so noisy, to become silent or to change the theme! One question expels another even to forgetfulness, without the confusion it occasioned having conducted to any good end.

"A mountain in labour uttered a cry so clamorous,
That every one ran at the noise, believing
It was about to be delivered of a city greater than Paris.
It brought forth a mouse!"

The potato disease is exhausted, and, thank God, tends to disappear*. It has been this season less general and less intense. We have spoken of it much, but it now engages much less of our attention. "Remedies are powerless to heal this disease," said the *Agricultural Chronicle*, of the second fortnight of August; and, in its turn, silence threatens to invade this question. We love to see a thing worthy of attention remain "the order of the day" to a complete solution. Whilst we have not found any means of preventing the return of the potato disease, we think there will be great utility in bringing it forward again: "It is the dead only that it is needful to bury." Besides, we are probably not far from the end.

A practical man, learned and modest, began in 1849, experiments, which he has renewed every year since then, having no other object than "the regeneration of the potato." His labours deserve to be known, and his experiments have need to be repeated by a great number, in order to be either confirmed or invalidated. In a word, they ought to be either repulsed or accepted, according as numerous facts, everywhere observed, and collected, establish or confute them.

M. Décoste, a former military veterinary surgeon at Sésanne, states that walking in his garden wholly occupied with the continuance and serious nature of the potato disease, the idea struck him of cutting some stalks of that plant, and pricking them into pots filled with mellow earth. He was quite in ignorance as to what this first attempt might lead; it was only a pilot balloon, and it went forth without pretension or interruption. The only thing that the experimenter proposed to himself was to observe carefully and note down exactly, all his observations. The result was favourable. M. Décoste had the satisfaction of seeing that most of the cuttings that he had planted followed the ordinary phases of vegetation. He obtained from them small, but perfectly healthy tubers, which he afterwards employed in making new experiments. Seven years of consecutive culture have filled M. Décoste with hope and confidence that he is possibly on the eve of a useful discovery, interesting in the highest degree to the agricultural world; and it is certainly the least we can do to give him the opportunity of rendering an account of his experiments:

"'Of all the means employed for multiplying the good qualities of the potato,' says Parmentier, 'and to prevent them degenerating, there is none more efficacious than sowing the seed. It is necessary from time to time to renew and perfect in this manner the species we intend to regenerate and propagate.'

"Unfortunately a multitude of experiments have invalidated this assertion, and proved that the seeds have produced crops of diseased potatoes.

"Up to the present time the process by cuttings appears to have a better chance, and offers more certain guarantees for the crop, than a perfectly healthy sowing, and of which the ulterior products should be exempt from the disease. Is it not, to say the least, to this conclusion that the results of the following experiments lead us?

"*First Year.*—In the month of August 1849 I pricked four cuttings of potatoes into a pot filled with a mixture of earth and vegetable mould. The stalks, preserving their verdure, gave out vigorous shoots. Towards the beginning of November the leaves faded from maturity, and the stalks became dry, as at the termination of all healthy vegetation. I then turned out the pot, and rummaged amongst the earth, and found at each of the cuttings there were tubers, healthy in appearance and varying in size from a hazel-nut to a walnut.

"*Second Year.*—In April, 1850, I planted the small potatoes produced from the cuttings of the previous August, 1849. In July following I took from vigorous and luxuriant shoots a number of cuttings, which were planted in different kinds of earth. This was undoubtedly the most effectual means of ascertaining the precise value of the process, either confirming or invalidating the results of the preceding crop.

* This was written in 1855.

"Placed in conditions more generale, and consequently less exceptionable than in 1849, these cuttings yielded to the common laws of vegetation; they faded before they resumed that vigour which had led me to select them; but this weakness of the stalks was of short duration. These soon recovered their primitive strength, and threw out in good time new shoots full of sap and hope.

"I was impatient of success, and wished to detect the facts in their progress and development, if I may so express it. During the first days of October I took up some of the cuttings, and already the roots showed themselves well furnished with small tubers of healthy appearance. There was nothing to do but to leave them to increase in size and reach maturity; and in November I gathered potatoes of excellent quality, and weighing on the average from 30 to 34 grammes (about 1 oz.).

"*Third Year.*—The crop of 1850 furnished me with the seed of my plantation of 1851, which was made in April, like the preceding one. The 5th of July I took cuttings, which were again pricked into various kinds of mould; the crop was taken up on the 20th of September, before completely mature: it was at once abundant, and fine in the quality of the tubers, which were sent, with the cuttings attached, to the exposition of agricultural products of the Agricultural Society of Chalons-sur-Marne.

"*Fourth Year.*—The potatoes of the harvest of 1851 were planted the 25th of March, 1852, namely—1st, in dry sand, such as is used in paving the streets; 2nd, in a sandy earth; 3rd, in a calcareous earth; 4th, in an earth with clayey subsoil; 5th and lastly, in an earth said to be of good quality, both by nature and its state of cultivation.

"The 10th of June I separated cuttings which I planted in the same soil as that of the plants from which they were taken.

"According to the proportions, the crop was satisfactory in each kind of soil. The cuttings pricked in the dry sand were frequently watered. The tubers had a thin and glossy skin, a firm and close pulp containing little vegetable water, and presenting to the taste the flavour of potatoes of first quality.

"Towards the 25th of July I had been able to take new cuttings from the first, and plant them in their turn, and I obtained from them a crop as abundant and fine. The vegetation of the first cuttings was so active and vigorous that I have measured stalks from half a metre to one metre in height (or from 15 to 30 inches). The tubers taken from the good earth weighed from 150 to 235 grammes (or from 4¾ to 7½ oz.).

"The experiment of 1852 presented this peculiarity, that the planting produced three crops in the same season, one the produce of the tuber itself, the two others from successive cuttings.

"The facts have been repeated precisely the same in 1853, 1854, and 1855, and they appear so much the more conclusive that they have left nothing to wish for, either in regard to the abundance of the crop or the good quality of the tubers. The disease has not appeared during the vegetation of the cuttings, and the potato obtained was excellent to eat and easy to preserve."

If we were allowed to give our conclusion, we should say:

From these seven years of conscientious experiment it follows that from potatoes planted in March or April we may in June or July take from each bunch some stalks, plant them with the precautions usual in like cases, and in the following October obtain from the cuttings a crop equal to that of the primitive plantation without the latter suffering from it in any manner whatever. In reality, the separation of the branches is made sufficiently above the soil to allow of there remaining on the stalk, thus cut, most frequently two eyes (axil of the leaves), from whence spring new shoots, which will amply suffice, with the non-mutilated stalks, for the complete development of the plant and the proper evolution of the tubers it ought to produce.

"The pulling of the bunches of potatoes proceeding from the cuttings has constantly yielded a crop equal to that of the bunches which had not had their stalks suppressed.

"In the diseased potatoes the first signs of the disorder exhibit themselves upon the stalks which first turn yellow, and sooner or later acquire a deep brown colour, then quite black and easy to be perceived. Sometimes, however, in times of drought, the spots, instead of turning black, assume a less decided tint, and become bleached, whilst the stalk dries up.

"In making cuttings for transplanting, we choose carefully the most vigorous branches upon the most healthy stools. In this above all lies the advantage of the process; for if in the number of cuttings any diseased stalks are selected, they will soon be endangered; the vegetation will be arrested, the branches dried up, before they are able to produce anything. The disease will thus be stifled in its birth. This is wonderfully explained Once separated from its centre of life, the stalk that is about to be planted needs all the integrity of its organs, to attract and to assimilate to itself, after a proper elaboration, all the materials necessary to its development, and the complete evolution of all its parts. The diseased stalk offers none of these conditions, so indispensable to its preservation, for the parts most essential to its existence are the most affected (epidermis utricles fibres of the Endophlæum, &c.); consequently it is soon weakened, and ceases to live.

"By the process of cutting, therefore, we should have no more to fear from diseased seed, since we can make use of no other than perfectly healthy plants.

"In any and every case the cuttings seem to possess a very great and real advantage over seed, even on the supposition that this latter (what experience does not warrant us in believing) offers all the guarantees desirable for the regeneration of the plant so deeply affected. In fact, in order to renew the plant by way of sowing, it is necessary to wait the crop of the seed, and thus lose a whole season; nor is it less necessary to obtain it of good quality; and upon that point the uncertainty lasts during a whole year. With cutting, on the contrary, we obtain two crops during the same season.

"Let us not forget to state that it is indispensable to allow to the cutting as many eyes as possible, for from this part of the stalk spring the tubers. The abundance of the crop is consequently strictly dependent on them.

"The culture of the cuttings presents nothing particular, demanding only the ordinary conditions required otherwise by all the weeded plants—a light and deep soil, that yields easily to the development of the tubers.

"In case of drought, it speaks for itself; we must not neglect to water at the commencement of the planting.

"One more word, in conclusion. Admitting that the reproduction of the potato by cutting gives only the means so much sought after, of regenerating that plant, our experiments will not less have demonstrated to a certain extent, that with a single sowing we may crop several times in the same season. Had we obtained only this result, still we should have congratulated ourselves on having devoted seven years of experiment in finding it. Let others now add to the facts which we have collected, by renewing them, the sanction they necessarily require before being adopted in the general agricultural practice."

The wishes of M. Décoste will certainly be heard.

Agriculture has ceased to be a practice of mere routine; and it knows how to fulfil the task imposed upon it. It has suffered too much from the scourge to which M. Décoste believes he has discovered a preventive, not to submit to attempts conclusive, by their importance, the easy means which is recommended to it by a conscientious experimenter, and, better still, by a wealthy man.

(Signed) EUG. GAYOT.

WENLOCK FARMER'S CLUB.

LECTURE ON ARTIFICIAL MANURES, BY PROFESSOR VOELCKER.

A meeting of the members of the Wenlock Farmers' Club was held at the Raven Inn, on Monday, Dec. 21, to hear a lecture on the "Agricultural and Commercial Value of Artificial Manures," by Dr. Augustus Voelcker.

Dr. VOELCKER commenced by observing that there are two classes of persons who, upon the subject of the utility of agricultural chemistry, entertain diametrically opposed opinions. One of them think nothing more is necessary for successful farming than to read one or two books upon agricultural chemistry, and perhaps Mr. Mechi's letters, or some similar popular treatise, containing a strange admixture of science and practice; and this kind of knowledge they believe will enable a man to dispense with that vast amount of experience which every one who has tried his hand at farming knows is requisite, no matter how clever a man may be, if he would make a living by farming; while the other class think that agricultural chemistry, like all other sciences, is, to use a plain word, all "humbug." The truth here, as in many other things, lies in the middle. A mere knowledge of science will never make a man a good farmer; but at the same time, it is of very great advantage if, in addition to practical experience, he has a knowledge of the principles of science. Moreover, young men with a scientific knowledge would make much greater progress in useful experience than others who were ignorant of the principles of chemistry. The great utility of science to farming is not so much direct as indirect—it does not dispense with that practice, without which no excellency could be acquired, but enables the farmer to make better use of it. Very frequently, in lectures of that description, the mistake was made of aiming at too much—a large number of subjects were mixed up together, and the audience went away more or less muddled. It was also not unfrequently thought that in order to make an impression a little exaggeration was necessary. The very fact, however, that this club had existed, and kept up with spirit for a number of years, was a sufficient reason, if he had no other, why he should not attempt in this way to create a little temporary excitement. He should confine himself to one very important subject—that of artificial manures, and attempt to convey some views on the subject, which he trusted would be of some use in their practice as farmers (Hear, hear). There could be no question as to the great improvements which have taken place since artificial manures have been introduced into farming. The great demand for artificial manures is the best proof that in many instances they have not been misapplied, for no man will spend money for a succession of years upon something which brings him no useful result. The fact, therefore, that new companies and new businesses are started almost everywhere, proves that artificial manures, when judiciously applied, are a great boon to the agricultural community. Within the last three or four years manufacturers of artificial manures have sprung up like mushrooms, and it was therefore not to be wondered at that some inferior descriptions have been offered to the notice of the farmer. It must also not be forgotten that in many instances artificial manures have proved complete failures. The question, therefore, arose, What is the reason of these failures? It was not always easy to discover the reason. In some cases artificial manures have been injudiciously applied; *i. e.*, in too large or too small quantities. He had seen guano used in quantities that would certainly do more harm than good—too large, that was, for the soils or crops to which it was applied, to the exclusion of farm-yard manure and other manures more suited for root crops. In passing, he observed that guano should not be used generally upon any soils for crops dependent upon the development of the roots. For turnips, mangolds, and other root crops, the manure should have a large proportion of bone material—phosphates, as the chemists called them. In some cases again, the failure must be attributed to the artificial manure which has been supplied; and he grieved to say that in the present day there was a much larger number of inferior than superior kinds of manures sold. The diagrams would show the analyses of different kinds of manure. One of them was the London Economical, which at one time made a great noise, and was used in different parts of England and Scotland. It was accompanied by a small volume of testimonials, all speaking of it as a most efficient manure; whereas it contained nothing which was known as possessing fertilizing properties in a very high degree. If any good effect had therefore been produced by its application, it must be attributed rather to the good farming, or to an uncommonly good season, which, as was well known, often was more effective than the best manure (Hear, hear). And indeed it was almost impossible by experiments, continued even for two or three seasons, to ascertain the practical value of a manure; but in the long run a really good manure will be found out. He remembered the time when there were almost as many people against guano as there were now for it. Not very long ago hardly any purchaser for bones could be found; and even now no bones were used on the continent, hence the large importations of that article to this country. Everybody knew that artificial manures were more efficacious under some circumstances than others; and why? Because the effect produced by artificial manure would be just in proportion as it supplied the ingredients which were deficient in the soil. Artificial manures sometimes failed too, by reason of the mechanical condition of the land being such that it could not produce its legitimate results. For instance, fresh bone-dust does not act upon the soil at all for the first year, very little the second, and only a partial effect the third. For want of sufficient air the material remains very much in the condition after the first six or twelve months in which it is put in. Excess of moisture was often another reason why manures were unproductive. Without good draining no amount of artificial or natural manure would produce a very large crop. It would be seen then that the practical efficacy of artificial manures is known by a variety of circumstances; and it would also be clear that the commercial value of artificial manure does not necessarily coincide with its practical efficacy—the commercial value of artificial manure being much more fixed in its character than the practical value. For instance, under some circumstances lime produced an astonishing effect upon the land; in other cases none whatever. In the neighbourhood of Cirencester no good farmer limes; and upon examination the soils are found to contain sufficient lime to meet the requirements of the growing crop. In the generality of cases, however, the soil does not partake of the character of the subjacent rock—most of our soils being soils of transportation, and do not belong exactly to the rock on which they rest. Hence a general geological knowledge will not be a sufficient practical guide—nothing short of an examination of the surface will decide when a man should lime and when not. The practical efficiency of artificial manure is determined by experience, and does not necessarily coincide with the price at which it is bought in the market, but on its particular adaptation to the land where it is applied. In most soils phosphoric acid was deficient, and hence really effective manures contained a very considerable proportion of phosphates. Again, in some descriptions of produce—corn, &c.—ammoniacal matter was of very great utility, because ammoniacal ingredients were generally deficient in the soil. It was also found that alkaline matter, potash and soda, produced very great effects when applied to the land. This was the conclusion, then, to which they must arrive: phosphates, and substances which, on de-

composition, are ready-formed ammonia; substances containing nitrogen; and alkaline matters, more especially potash, are the most universally efficient manures. These are also the more expensive manuring constituents, so that to some extent the practical and commercial value of artificial manure go hand in-hand; but, on the other hand, it would be wrong always to determine what you should pay for artificial manure by the effect which it produces. In some cases he had seen superphosphates applied upon lands which contained in themselves a large quantity of phosphates, and therefore the extra supply did no good whatever. These, however, were exceptional cases, and did not often occur. The question—and a very important one it was—then arose: what description of manure ought you to use? and secondly, what ought you to pay for a manure of a certain character! No person should understand so well as the farmer himself what is really required for his particular farm; and in practical matters no fixed rule can be laid down. Some general hints may be thrown out which have been collected from a number of experiences in various districts, which are useful as a basis; and it is from the experience of farmers living in many counties in England and Scotland we know that, generally speaking, ammoniacal or nitrogenous matters are peculiarly beneficial to corn crops. In making this statement, he left entirely untouched the question whether mineral substances are not an advantage in some instances for corn. He knew that they were. But, on the whole, substances rich in nitrogen are applied with great benefit to corn crops. Hence good rotten dung was better than fresh manure, because weight for weight it contained a larger amount of nitrogen. He wished them to understand that he did not recommend well-rotted dung under all circumstances; because it was generally better to take the manure as fresh as possible, and get all that was valuable out of it upon the land. But because rotten manure contained a larger amount of nitrogen in the shape of ammoniacal salt, it generally produced greater effects than the fresh. So with guano—a small quantity of this produced such extraordinary results, because it contained in one cwt. as much ammonia as a ton of well-rotted farmyard manure. The effect of manures did not depend upon anything mysterious. Manure from half-starved animals would never be very good, no matter how much it was turned, and it was not the mere rotting that made it good. In good Peruvian guano there was from 16 to 17 per cent. of ammonia. It was important that they should recollect that there was a great difference between good Peruvian guano and that which had been brought over since the best layers had been cleared away. In good guano there was also a large proportion of phosphates or bone earth. The solid part of bones consists of phosphoric acid and lime, and this would explain why it is that good guano produces a good effect upon turnips. Experience had likewise shown that phosphoric manures were especially beneficial to root crops—bone dust and some inferior kinds of guano, having phosphate of lime as their characteristic constituents, were the manures best adapted to turnips, mangolds, et cetera. Alkaline salts was a very good manure for root crops. It would be admitted by all who had any experience in the application of artificial manures, that guano and superphosphate were the two most valuable, in a commercial point of view, that could possibly be used in agriculture. Guano, it was well known, was the most successful agency they could apply to wheat or grain and grass lands, while superphosphate was most applicable to roots. Saldanha guano, which was cheaper than the best Peruvian, produced a better result when applied to roots, because it contained more phosphate. If they depended entirely upon guano they would have too much leaf and not sufficient bulk. A series of experiments which he had continued for four years convinced him that they could not dispense entirely with ammonia for root crops, but it produced frequently more harm than good. To spend, therefore, a large sum in buying ammonia (which is a very expensive material) for root crops was to make a great practical blunder; for phosphate was one-seventh the cost, and produced infinitely better results when applied to roots. Commercially speaking, ammonia is the most expensive ingredient used in superphosphates. Alkaline salts, which are occasionally found in artificial manures, are likewise expensive materials —too expensive, in fact, to be used with advantage in agriculture. For this reason most artificial manures do not contain any appreciable quantity of these expensive salts—the effect they produce upon the land is not commensurate with their cost. Bearing in mind, then, that the value of artificial manures is to be estimated by the amount of nitrogen (ammonia) and phosphates which they contain, there would be no difficulty in applying this test to the different manures sold to farmers. The Economic Manure, to which he had referred, contained very little of these ingredients. A sample of Mexican guano (as would be seen from the diagram) contained only 18 per cent. of phosphate of lime (one-third of that contained in bone dust) and a mere trace of ammonia. Another manure, advertised as the very essence of Peruvian guano, consisted chiefly of burnt clay, carbonate of lime, and a little sheep's dung. (Laughter.) The learned professor then directed attention to the diagrams showing the composition of the best guano (for corn) and the best superphosphates for root crops. These manures varied considerably in their component parts, and their effect when applied to the land must also be vastly different. In one of the samples it would be seen that there was not more than a fourth as much phosphate as that contained in another sample. In the highest there was no less than 40 per cent. of soluble and insoluble phosphates, and this could not be sold for less than £12 per ton. With this exception the other manures—though varying so much in quality—were about the same price, from £6 to £7 10s. How could you ascertain which really was the most valuable article? To take it up, and smell it, in order to discover its quality, was simply ridiculous. In the course of the year he examined some hundred specimens of superphosphates; yet he had not yet attained to that practical acquaintance with it to be able by looking at it to ascertain whether it was good or bad. They all looked very much alike, and smelled more or less disagreeable. In nine cases out of ten, as he had said, the farmer wants either guano or superphosphate, and he should confine himself to these manures. As to guano, when farmers buy this they ought to receive in writing a guarantee that it really is genuine Peruvian with which they are supplied. But if there is any suspicion, a very simple test would prove whether it is well grounded or not. A trustworthy opinion of its genuineness could be obtained at the moderate expense of seven or eight shillings. Without this, however, good Peruvian guano has such marked qualities, and varies so little in its composition, that any one may for himself ascertain its quality. When burned it should leave one-third of itself a perfectly white ash—adulterated guano produces more ash, and is coloured; this ash, on being dissolved in acid, should leave no perceptible amount of sand. At any rate, it would be easy to obtain in writing from the dealer a guarantee that what he supplied is genuine. Superphosphate is a manure that can be produced in a variety of ways, its efficacy depending, unlike that of guano, on the amount of phosphates it contains; and not only upon the amount of material, but upon the state of preparation it has undergone. Between soluble and insoluble phosphates there was a great difference, not only in their efficacy, but in the expense to which the manufacturer is at to produce them. Manuring constituents to enter into plants must become soluble; phosphates, when in a condition to be readily taken up by plants, must be far more efficacious than the same constituents in a state in which they cannot be absorbed by the rootlets. To illustrate this, a valuable raw material was coprolite, or fossil remains, which had been not altogether correctly termed coprolites. That term signified the petrified excrement of animals; but the substances known as coprolites were in reality the fossil bones of those animals which in distant ages inhabited the regions where they were found. They were also more correctly known by the name of pseudo-coprolites, and were in reality nothing more than fossil bones. With regard to their composition he might observe that they did not contain any organic matter; they contained only mineral substances, and amongst others phosphate of lime. In its crude state, however, this phosphate was of no use whatever; it produced no effect, no matter how finely it was powdered. He had tried it repeatedly, some eight years ago; and although finely powdered, it remained insoluble, even when attacked by acetic acid. Hence there was always some risk of having a portion of insoluble and useless material in superphosphates. Bones were rendered only soluble by expending large sums of money in buying expensive acids; hence soluble bone earth is worth at least three times as much as it is in its crude state as insoluble phosphate. It may be asked if, when these acids came into contact with the tender fibre of the plant, would they not be injurious to it? There was, however,

in most soils a natural provision against this; there was generated in the soil lime, or oxide of iron, or alumina, or some other constituent, which neutralised any such effect. Even oil of vitriol was soon dispersed and neutralised by these constituents. When applied to land, therefore, the superphosphate became insoluble. Hence it did not enter into the composition of the plant as applied. But they would be inclined to ask what was the value of the manure if it did not enter into the composition of the plant immediately on its applicatiou? To this he would reply that the great value of superphosphate was owing to its sub-division, for in its finely divided condition it possessed properties differing very materially from ordinary insoluble phosphate of lime. The lecturer took a solution of bone dissolved in acid, to which he added ammonia. The result was, that the whole of the phosphate was rendered soluble, the solution appearing to be converted into a thick glutinous mass. In this finely-divided state, it was easily taken up by the plant. This he illustrated by adding to the precipitated phosphate some strong vinegar (acetic acid), when the whole was instantly dissolved, although this comparatively weak acid would scarcely have had any action on bone-dust, if applied in the first instance; thus showing that by resorting to this mode they obtained the advantage of more energetic action. Pounded or ground bones could never be divided into such fine particles, or spread so squally or evenly over the soil, as could be accomplished when dissolved in the manner he had described; and their bulk greatly increased, for the one was mechanical action and the other was chemical. When bones were used first it was usual to break them into one-inch pieces; when they became dearer they were reduced to one-half the size, for the farmer discovered that when more uniformly spread half the quantity was just as good. And so in the application of artificial manures—it was everything to have it, not here and there, but well distributed, so that the roots of the plant could reach it, and take up the ingredients congenial to its growth. Some persons contended that it was an advantage to have a portion of the phosphate insoluble, in order that it may remain after the rain had washed away the soluble portion, to maintain the after-growth of the plant. This was all moonshine and theory, and never could have been founded on practice or correct principles. It was certainly a most convenient doctrine for artificial manure manufacturers to say that it was as well, and better, to have a portion insoluble, because the more soluble the phosphate was the more expensive it was. The conclusion, therefore, to which he would ead them, was this: In buying superphosphate, let them ascertain that they had a large proportion of soluble phosphates. There was no reason why the farmer should go to the expense of an analysis; let the dealer supply one; it was his business to show what he had to sell. If a dealer had an objection, and said, "My manure is as good as anybody else's, but I cannot tell you exactly how much soluble phosphate there is in it," they may be sure that in nine cases out of ten he had not a very good article to show. In the absence of an analysis, the dealer should be required to give a guarantee that it contained so much of soluble phosphate; for upon this the value of the manure chiefly depends, and not only upon the amount of its various constituents; analyzation, therefore, was not always a sufficient test of the full value of a manure, although of course the material must be present to have a really efficacious manure. He was most anxious to point out how desirable it was that the farmer should not be content to buy his superphosphate, relying entirely upon the respectability of the dealer. Frequently the dealer may be a very honest man, and yet may not know himself what he is selling; the manufacturer himself may be a perfectly trustworthy man, but he may have some very erroneous notions as to the relative value of soluble and insoluble phosphate; and such ideas may not enable him to produce so cheaply an effective manure as another manufacturer. The farmer is not to pay for the character of the dealer or the manufacturer, but for the character of the manure (Hear, hear). The cheaper he could get it the better, but by all means secure a guarantee. These few practical hints he hoped would be of advantage to them in purchasing artificial manure. It was only by these means they could check the nefarious practices which now and then are attempted upon the farmer. The adulteration of guano had been practised last year to a far greater extent than he had ever known it before—as many as three-fourths of the samples he had received were adulterated; on the other hand. superphosphates appeared to be getting more valuable, and this he attributed to the general demand which was now made for guarantees. After thanking them for their attention, the learned professor resumed his seat loudly cheered.

The CHAIRMAN said he was sure all felt equally with himself much indebted to the learned gentleman for his able and lucid address. He had never heard a plainer elucidation of the principles which rendered artificial manures of importance to soils. There had been lately discovered, as of course the Professor was aware, some large deposits of guano at Kooria Mooria, in the Eastern Seas; and it appeared that there was now upon the seas something like 100,000 tons of this guano. From the analysis, it appeared to be equal in ammonia to the Peruvian, and, like some of the other guanos, to have a larger proportion of phosphates. They would all readily agree that it was to the root-crops they must chiefly look; and not only how best to prepare the land for the present crop, but how to get it into good condition for the subsequent produce. He did not gather from the lecture whether ammonia was so volatile as to be less available for subsequent crops—whether it was all absorbed by the cereal crop; and this was a very important question for the farmer. Peruvian guano, at its present price, was almost a forbidden fruit to the farmer; and it was certainly worth inquiring, whether the ammonia, which made it valuable, benefited the land beyond one crop. It was most important that they should know that this expensive manure was not adapted to root-crops; for, if they could buy a better article for little more than half the money, why should they not do so? It would be a great advantage if farmers could be got to adopt some rule; but of all men on earth to get to stick to a point, farmers were the most difficult. If you talked to half-a-dozen different men, you would find that they each entertained a separate opinion; and nothing would induce them to take any trouble to ascertain the truth. It might not be very agreeable to hear this; but it was quite true. The result of that day's market, when the farmer was offered 6s. 6d. for his wheat, was not very agreeable: it was not calculated to make him very happy, seeing at how much trouble and expense he had been to rear it. Their duty clearly was to be as saving as possible—to ascertain which was the best manure, and to buy that, and not confide altogether to the character of the dealer. Nitrate of soda was some time ago highly recommended as a manure for cereal crops; and, as he understood there was a large supply on the coast of Peru, he could not understand how it was that it was not exported in larger quantities than at present. Another subject of some importance to the farmer was top-dressing. He should like to know, from some of the practical farmers present, whether any practical benefit arose to the crop from top-dressing. A dressing of nitrate of soda or sulphate of ammonia made the crops look splendidly green; but did any real good accrue!

Mr. W. THURSFIELD said he had found great advantage from top-dressing.

The CHAIRMAN said, it was probably from want of accurate observation, but he perceived no practical benefit to the crop on that part of the field which he had top-dressed; it was much greener, but at harvest he saw no difference. It was very true that they could not lay down any general principles; every person ought to be able by observation to know what was best suited for his own land, for there was scarcely a farm of any extent which did not consist of several kinds of land. Hence the importance of knowing sufficient of general principles to be able to apply one's common sense to particular cases. The value of an institution like that at Cirencester, where the students were made acquainted with the practical application of science, was not sufficiently known and could not be over-estimated. It would be au excellent thing if farmers could send their sons there for a short time, and the knowledge that he would acquire would certainly make him a better farmer. What could be more important than for the farmer to know that coprolite in an undissolved state was useless on the land? It was, however, with some surprise that he heard that one cwt. of guano was equal to a ton of farmyard manure. To put upon land 3 or 4 cwt. of guano was a good dressing—three or four tons of manure would do nothing at all.

Mr. W. THURSFIELD asked what kind of bones were best—those which were calcined, or those in which the glue was left.

Dr. VOELCKER said, the value of the bones would be reduced just in proportion as the nitrogen was taken out of them; but inasmuch as the phosphate was made more available the deterioration was more than made up. He would therefore rather have boiled bones.

Mr. THURSFIELD inquired how it was when he put lime upon a field for barley, after it had been manured by guano and superphosphate for turnips, the crop was not so good in that part of the field as in the portion where he put no lime?

Dr. VOELCKER thought the land did not require lime after being well manured with superphosphate. In answer to the Chairman the learned Professor further said, that he did not intend to convey that no ammonia was beneficial to root crops; but generally speaking the plant absorbed enough of atmospheric ammonia, and any large amount applied would do harm. In speaking of coprolites he meant to say that although they were useless to the farmer, they were of the greatest use to the manufacturer. All soils more or less stored up with great care the ammonia—the only exception being loose soils. If, therefore, he had his choice of manures for root crops he should take nothing but phosphates, for in most cases animals were fed on the roots and supplied, with other sources, sufficient ammonia.

The CHAIRMAN said, his land would be in a pitiable mess if he were to feed on it, and it would take some time to bring the land into a proper state. Strong land, in his opinion, was the best for turnips—of course he did not mean wet land, because land not drained, with a quantity of sour water upon it, was not conducive to the health of any plant. But those lands which were most favourable for growing swedes and turnips were just those which the farmer could not eat off. He presumed, however, that the Professor meant that if the turnips were taken to the stall, and consumed there, the land ultimately received the manure.

Dr. VOELCKER: Certainly; for, to eat off some soil would be to ruin the land. With respect to top-dressing, he had always looked upon this as patch-work, which on a good farm should be dispensed with, although it was very useful now and then. But when the farmer had been prevented prosecuting his regular work, and the land was not in a good state, a top-dressing of nitrate of soda and salt—applied in the spring—was very beneficial. To manure well in rotation however would enable them to dispense in a great measure with top-dressing, although on grass land this was of the utmost utility.

Mr. THURSFIELD appealed to one or two gentlemen present to whom he had recommended his plan of top-dressing, and they said it had answered.

Rev. H. W. WAYNE mentioned that some soils, upon which very poor crops of grain were given, were extremely deficient in alumina. He wished to know whether alumina could be applied to the the land in a concentrated form, or must it be carted in the shape of clay?

Dr. VOELCKER answered in the negative.

Rev. H. W. WAYNE said there were some springs in that neighbourhood, which contained in solution a large amount of lime; now he should like to know if it would be worth while to mix salt with this water, where it could easily be conveyed over the land, and thus have a deposit of carbonate of soda.

Dr. VOELCKER replied that ordinarily there was in water sufficient lime to answer all practical purposes; and the experiment would not in his opinion produce any marked result. In reply to another question the learned professor said, superphosphate by being diluted was not made more fit to apply to plants but inasmuch as it could by being diluted be so much better distributed over the land, immense benefit resulted from using the liquid manure-drill.

Rev H. W. WAYNE then in very complimentary terms proposed a vote of thanks to the learned lecturer; and after making some remarks upon the utility of these gatherings, referred to the curious fact that, according to an old Roman writer, the ancient Britons were in the habit of using as manure what they took out of the mines, thus showing that from a very early period our ancestors had been accustomed to enrich the surface of the land.

Mr. BLAKEWAY seconded the proposition with much pleasure. The meeting ought to be much obliged to the talented fecturer for the important knowledge he had communicated, for there was not a farmer present who would not be able to see that he could buy a manure to answer his purpose better than guano at half the cost.

Dr. VOELCKER in acknowledging the compliment said, the difference in price was not the only advantage gained; for in an experiment which he had made upon some poor land, he found that guano produced about six tons per acre, while superphosphate produced double—nearly 12 tons.

Mr. FOWLER proposed a vote of thanks to Mr. Benson for the able manner in which he had presided over the meeting.

Mr. EVAN DAVIES seconded it. It was often the case that farmers prided themselves upon the amount of money they had expended in top-dressing, without, he was afraid, carefully weighing the results. Last year he top-dressed part of a field; and he must confess that, so far as he could observe, there was no difference in the crop between that which was top-dressed and that which was not. The harvest came upon them rather suddenly, and he was not able to weigh carefully the product of each portion as he intended to do, otherwise he should have been better prepared to give the results than he was at present. The remarks of the Professor upon the subject of soluble phosphates should be carefully considered, for it was now clear that they should secure those manures which had not only phosphate in their composition, but having that valuable ingredient in a soluble form.

The CHAIRMAN, after thanking them, asked what protection the farmer had that he was supplied with real phosphates? Clearly but one—to make the manure himself, by buying the bones and dissolving them in acid.

Dr. VOELCKER thought it was certainly not the best plan for the farmer to make his own superphosphate. Upon their farm, up to within the last three years, they had manufactured their own superphosphate, but they had now discovered that it was much better to buy it ready manufactured, in addition to the inconvenience of doing so. If the buyer obtained a guarantee that the manure contained a certain quantity of soluble phosphate, he wanted nothing more. This constituent was a distinct chemical substance, and how the manufacturer produced it was nothing to the farmer. The manufacturing of artificial manures was now quite an art; and the superior appliances at the disposal of the large manufacturer rendered it easy for him to produce a good manure at a price not far above what the farmer would have to pay for the crude material. Thus many intelligent manufacturers make a better superphospate than can be made from bones and acids alone.

After a little further conversation, the meeting broke up.

DR. VOELCKER ON THE COMPARATIVE VALUE OF ARTIFICIAL AND FARM-YARD MANURES.

On Tuesday Professor Voelcker delivered a lecture on the above subject, in the Lion Rooms, Shrewsbury. Mr. Joseph Meire, of Berrington, presided.

The attendance was not large.

The CHAIRMAN said the subject upon which they were about to hear a very interesting leeture was a very important one to the farmer.

Dr. VOELCKER said there had been a good deal of talk about the relative merits of farm-yard manure and artificials. Some would have nothing but the former, while others evidently thought the perfection of good farming was to use an unlimited quantity of artificial manure. Many of the latter gentlemen troubled themselves very little about what they really bought; it sufficed for them to expend a certain amount of money on some description of artificial manure, which might be entirely valueless for their particular purpose. Such, for instance, as the London Economic, the Essence of Guano, and others. Now, farm-yard manure was an excellent thing in its proper place, and so was any other description of manure. Some artificial manures, which were exceedingly valuable, lost their efficacy from being improperly applied, and a great quantity of valuable manure at the present day was wasted on farms for the want of knowledge necessary for its application. Those who had not sufficient intelligence or general knowledge on the subject of plants would be less likely to go wrong if they followed the old-fashioned routine and used farm-yard manure, than by using artificial manure, which at least would be of no use to them. Some knowledge ought to be had of the wants of the different crops that grow in rotation. Those wants could not well be laid before his

hearers without a reference to the character or properties of the soil to which they were applied. On the whole, the proper system of manuring required a great deal of rudimentary knowledge, which could not be treated of in a single lecture. He would therefore rather offer a few remarks on the comparative advantages of natural and artificial manure; and each of these possessed peculiarities of their own, which rendered them perfectly well adapted to special purposes. As would be seen on reference to the diagrams, one peculiarity of farm-yard manure was its extreme complexity of character. [The diagram referred to contained the analysis of the component parts of fresh and rotten manure.] It contained both organic and inorganic food, and was applicable to a variety of crops, such as corn, root crops, and grass land; and this, no doubt, was the reason why farm-yard manure was entitled to the name of universal manure. It contained everything required by our cultivated crops. But he did not say that it should always be used indiscriminately. Another peculiarity of farm-yard manure was that it exercised beneficial effect on plants, not only supplying direct food to them, but producing a highly beneficial mechanical effect on the soil, especially on stiff clay land. He was a strong advocate for long dung being applied as soon as possible. In the yard manure one great peculiarity was the large amount of water—in fact, this amounted generally to 66 per cent., and in rotten it amounted to three-fourths of the whole bulk; so that for every ton of active manuring matter, the farmer has to cart three tons of useless materials, even supposing that the remaining ton is composed of nothing else but valuable fertilizing constituents. This would explain why it was that artificial manures were especially adapted for hilly districts and for fields removed a considerable distance from the farm-yard. He did not think that farmers always took a sufficient account of the wear and tear of horses and men in the transit and application of that manure. If the subject were carefully considered, the farmer would think twice before he carted a heavy load of farm-yard manure some eight or nine miles from a town, and afterwards applied it to a remote field on the farm; and he would also hesitate before producing farm-yard manure at any expense. Under some circumstances, which every farmer ought to know best for himself, feeding cattle did not pay at all; farmers sometimes made up their minds to feed at a loss, calculating on something for the manure. But it was a very delicate question whether this was the best way of producing manure, or whether it was not better to use the ordinarily-made manure, and apply it in connection with artificial or special manure, the latter term showing that it was adapted for special purposes. If a farm was not in good order, it ought to be brought round by general manure, such as farm-yard manure; but when it was in better condition, to make it go as far as possible, special manure must be resorted to. A peculiarity in artificial manures was that they supplied special fertilizing ingredients to the exclusion of some others which were abundant in farm-yard manure. For instance: In the best Peruvian guano there was a high per-centage of ammonia, with about 20 or 25 per cent. of phosphate of lime; and that guano was applied for getting an additional crop of corn. Some other artificial manures—bone-dust, for instance—were valuable on account of their containing phosphate of lime, which was favourable to the production of roots, nothing tending to the rapid development of bulb so much as that. He did not mean that phosphates were of no use to corn crops In some soils they produced a marked effect, and he had that morning recommended a gentleman to use superphosphate by way of a trial, to keep up his wheat. There had been a good deal of talk about a deficiency of silica in soils, which prevented corn from standing up. It was remarkable that soils peculiarly liable to corn lying down generally contained a high per-centage of silica. From observations that had been made on the subject, he was inclined to think that what had been said about silica must be regarded more as a theory rather than a resting on well-ascertained facts. It had not yet been ascertained how it was that some crops were stronger than others; and until that was found out, it was of no use reasoning upon the matter. Corn become laid down from a variety of reasons. If the land contained a supply of all the elements necessary for the growth of the plant, a dressing of guano produced a coarse wheat, which often became laid down. When wheat became laid down it arose from something in the soil being in too large proportion. Some people had a curious way of estimating the skill of the farmer by the amount of the manure which he put on his land. Some men were content with eight tons of farm-yard manure, while others used as much as twenty tons to the acre. The farmer, however, who tried the larger dose did not often repeat the experiment, for he became convinced that, in farming, what was good in one instance was not good in another. The great advantage of artificial manures was that they contained special fertilizing ingredients to the exclusion of other substances, and hence its adaptation to special circumstances. How were these special circumstances to be ascertained? He had no doubt in his own mind that bone dust or superphosphate mixed with farm-yard manure would be of great advantage, as it would supply the element which was very much deficient in farm-yard manure, especially where the manure was produced by young and lean stock, which absorbed all the phosphate of the food; in the manure from fattening animals there was a large proportion of this substance, and hence its great value. Phosphates generally speaking were more suitable for root crops, but it was impossible to lay down general rules; the farmer himself ought to be the best judge, whether in order to obtain a good crop anything else was required. Turnips did not live alone upon phosphate; they required a variety of other substances—lime, soda, potash, and other fertilizing matters. It depended upon the farmer to find this out, and no one else. There was a good deal of land in this part of the country which required nothing more, in order to obtain good root crops, than bone in an efficient state of preparation. The learned professor then went on to observe upon the constituent parts of guano and superphosphate, and their application to particular soils and for particular crops. [The substance of this part of his lecture will be found in our report of the Wenlock Farmers' Club]. He illustrated the immense importance of examining the manure we buy, by referring to the following table, which proved that some superphosphate contained four times as much valuable fertilizing matters as others:

COMPOSITION OF SUPERPHOSPHATE OF LIME.

	I.	II.	III.	IV.	V.	VI.	VII.	VIII.
Water	19.26	20.53	14.40	22.03	20.37	8.91	10.80	26.89
Organic matter	16.10	14.76	8.93	trace.	25.71	—	4.21	2.08

Equal to ammonia	2.01	1.065	1.75	.20	1.42	—	.41	.25

Mr. GEORGE DAVIES, as a farmer, was much obliged for the able and practical lecture which they had just heard. He wished to know if the learned professor could tell him how red clover could be retained on light soils from February until June. He had some years ago conversed with Dr. Pepper on this subject, and was now in communication with Mr. Nesbit, but the latter gentleman had not answered the question he now put.

Dr. VOELCKER said, this question was a most important one, which it would be most desirable to solve. About four years ago, he paid some attention to what was called "clover-sickness;" and, like most beginners, in two months he fancied he knew something about the matter, and threw out some suggestions, with a view to remedy the evil. Having, however, followed up the question in various operations, and in the laboratory, and after some long correspondence, he had come to the conclusion that, upon the subject of clover-sickness, he knew as much or as little as the man in the moon.

Mr. DAVIES asked if the fermentation of ordinary manure would render chipped bones sufficiently soluble to be of use to the crop?

Dr. VOELCKER thought it would be quite sufficient; and, after one turning, the bone-dust would disappear. It would, in his opinion, be a very great advantage to use bone-dust in that way.

Mr. PAYNE inquired if the Professor recommended long manure to be ploughed in, or used as a top-dressing?

Dr. VOELCKER said in very stiff land it would be better to plough it in, as in that way they obtained the full advantage of the manure.

The CHAIRMAN, in the course of some observations, asked if the plan recommended for keeping up the wheat was by stiffening the straw? If so, superphosphate would be much more likely to do that than ammonia.

The PROFESSOR said he knew, in some instances, that superphosphate stiffened the soil; but that was a different thing from recommending it for the purpose of stiffening the corn. Ammoniacal manures certainly had a tendency to make corn go down, and should, therefore, be used very carefully.

Mr. GEORGE DAVIES then moved, and Mr. GEORGE WATTON seconded, a vote of thanks to the lecturer, which was cordially carried and acknowledged.

A similar compliment was, on the motion of Mr. NEVETT (Yoreton) accorded to the Chairman, in acknowledging which,

Mr. MEIRE expressed his regret that there was not in the county town a club where farmers could meet and discuss subjects connected with the improvement of the land, and other subjects of the greatest importance to the farmer. The information they had received that day was proof of how much could be gained in this way.

The meeting then separated.

REPORT ON THE CATTLE PLAGUE, STEPPE MURRAIN, OR RINDERPEST.

BY JAMES BEART SIMONDS,

PROFESSOR OF CATTLE PATHOLOGY IN THE ROYAL VETERINARY COLLEGE, LONDON.

Epizootic diseases, and particularly those that have prevailed among cattle and sheep, have in all ages excited much attention, and taxed the pen of the faithful historian, as well as the cultivator of the science of medicine, to record their successive outbreaks and devastating effects. It is not, however, our intention in this report to follow in a succinct manner the account which has been given of these diseases, extending, as it does, from the period of the infliction of "a grievous murrian" of "boils and blains" on the cattle of Egypt, as a Divine punishment to the obdurate Pharaoh for resisting the command to let the Children of Israel go, down to our own times; but to record the result of our investigations into the nature and consequences of the disease which recently seemed to threaten to invade our shores. Whether "the murrain" that fell upon the cattle of the Egyptians has been permitted in an altered or mitigated form to remain as a scourge to succeeding nations is a problem which cannot, we opine, be satisfactorily solved by any supposed resemblance which our present cattle plagues may bear to the one described by the sacred historian. This fearful and miraculous visitation must be regarded as the chief of these scourges, however destructive they may since have been.

In the times of the ancient Greeks and Romans the outbreaks of these diseases were not unfrequent, and numerous records of them are left by Homer, Plutarch, Virgil, and others. Columella, at about the commencement of the Christian era, speaks of them as contagious maladies; and Vegetius, in the fourth century, treats largely of their contagious properties, and recommends that the diseased animals should, "with all diligence and care, be separated from the herd, and put apart by themselves." Fracastorius and Weierus also describe the sad effects of one of these visitations in 810, when it is said that the greater part of the cattle perished throughout the Emperor Charlemagne's dominions.

The first recorded instance, however, which we find of the cattle in England being affected by one of this class of maladies is in 1713-14, at which period an epizootic, that for a few years previously had prevailed in several continental states, suddenly broke out here, and swept off many of our cattle. No account sufficiently explicit upon the nature and progress of the disease has been handed down to us, so that it is difficult to speak with certainty of its true characters, and much more either of its duration or the amount of loss which the country sustained. It appears, however, that the malady possessed many of the features of *Eczema epizootica*, now common among us, and it may possibly have been identical with this disease. The infection seems to have been communicated by the saliva, as it is said that "when this is dropped on the grass, and sound animals are immediately placed on the same pasture, they contract the disorder; and in some bullocks the tongue was inflamed and covered with many red blisters."

This malady was succeeded in 1744 by one of far greater importance, because attended with a far greater fatality. The disease in question early attracted the attention of the Government, who promptly adopted vigorous means of arresting its progress. It is asserted that the malady first appeared in the neighbourhood of London, whence it extended over the length and breadth of the land, destroying hundreds of thousands of cattle, and continuing its devastating effects with almost unmitigated severity down to 1754-5. Its introduction here has been differently accounted for; but it is pretty

generally attributed to the importation of two calves from Holland by a farmer residing at Poplar, with a view of improving his breed, and in whose systems the disease was incubated.

Dr. Layard, in his Essay on the disease, says, however, that an opinion prevailed that it was brought over by an English tanner, who had purchased "a parcel of distempered hides in Zealand very cheap, because they were forbidden to be sold there, and should have been buried." It seems, therefore, to have been confidently believed at the time that the disease was an imported one—a circumstance of much practical value, now that we are receiving several hundreds of cattle week by week from the Continent; although, as this Report will hereafter show, our own investigations have proved that no fear need be entertained at present of "the great cattle murrain" visiting our shores. Notwithstanding the deep and painful interest which this disease excited, and the efforts made by the Government of the day to stay its ravages, no correct estimate can be formed of the numbers of cattle which were lost to the country from its duration and extension; but it was ascertained by one of the Commissioners appointed by the Government that in Nottinghamshire alone 40,000 head of cattle perished in six months, and in Cheshire upwards of 30,000 in the same space of time.

By a special Act of Parliament, the King in Council was empowered to issue such orders as were deemed the most effective to arrest the progress of the pest. Instructions were thereupon given,

1st. For the killing of all the infected animals, and burying them entire with the skins on, "slashed from head to tail," that they might not be used for the purpose of the manufacturer.

2nd. For the burning of all the hay and straw used about the animals.

3rd. For the cleaning and fumigating the sheds, &c., and for no sound cattle to be put in them for two months after the removal of the diseased.

4th. For no recovered animal to be allowed to go near others for a month after its convalescence.

5th. For no diseased cattle to be driven to fairs or markets, nor for the flesh to be used as food for dogs, &c.

6th. For no *healthy* cattle to be removed from a farm where the disease had prevailed in less than a month after its disappearance.

And, lastly, orders were issued for the notice of an outbreak to be immediately sent by the farmers to either the constables, churchwardens, overseers, or the special inspectors appointed by the magistrates acting for the parish or district. The Government also undertook to pay forty shillings for every ox, bull, or cow which was killed, and ten shillings for every calf, with a corresponding price for their skins.

Mr. Youatt, in his account of the disease, as published in the work entitled "Cattle," says, "Of the propriety of this bonus for the destruction of infected cattle, there cannot be a doubt, for there were numerous instances in which those who began to kill the sick as soon as the distemper appeared among their cattle, lost very few; but others, who would kill none until their own folly had made them wiser, did not save more than one out of ten."

Many difficulties were thrown in the way of carrying out the instructions, and not a few impositions were practised by some designing persons claiming the award for old and worn-out animals, as well as for those which were suffering from totally different diseases. In this day, now that veterinary surgeons are practising in every part of the country, such frauds would scarcely be attempted; and we believe, in the event of occasion requiring it, that a system of inspection, comparatively inexpensive, might be devised which would effectually prevent any instances of the kind.

It is further recorded that in one year, the third of the existence of the disease, £135,000 was paid out of the Treasury as a recompense for the cattle killed according to the prescribed orders, and that during the same year 80,000 head of cattle were killed, and nearly double that number died from the disease. To meet this alarming state of things, and the difficulties which sprung out of the adoption of the measures of the Government, various other Orders of Council were promulgated, and in the *third* order we find that *no* cattle, fat or lean, would be suffered to pass the Humber and the Trent northward from its date, namely, January 19th, 1747, to the 27th of the following March; the object evidently being to protect the cattle in the northern counties by cutting off all direct communication between them and the infected districts for two months.

Newby, in an appendix to his work on mangel-wurzel, states that the cattle fair at Barnet had its origin in the existence of this disease. "The fair," he says, 'formerly kept at Islington, till the distemper, which raged violently among the cows at that place in 1746, obliged the Welshmen to remove to Barnet, where it has been continued ever since."

Great as were the losses, no reasonable doubt can be entertained that they would have been much augmented had not the Government taken the course it did; and we also fear that the continuance of the disease would have been extended over a far greater number of years than it was. The attempts at cure were not satisfactory, and very little was known of the true nature of the malady even by those members of the medical profession who gave attention to it, for at that time there were no scientifically educated veterinary practitioners. After a careful perusal and analysation of the writings of the different physicians who have treated of the subject, we believe that we are justified in saying that the malady was identical with that which has recently excited so much fear and alarm in the public mind, as being likely to be introduced from the continent.

From the period of a subsidence both in the amount and virulence of this cattle pest in 1754-5 until its final departure a few years afterwards, England appears to have been singularly exempt from epizootic diseases, and to have remained so down to August, 1839, when great anxiety was created by the sudden and almost simultaneous appearance of a "new affection" (although probably of the same nature as that of 1713-14) among the

cattle in different parts of the country. The earliest accounts which we received of the outbreak came from Norfolk, and there seems no reason to doubt that it was here that the disease was first observed. Cattle of all ages and under every variety of system of feeding and management became the subjects of the malady, which was recognised by the existence of vesicles upon the upper surface of the tongue, inside the lips, and the dental pad. Vesicles were also formed between the digits, and occasionally upon the teats and udders of the cows. The existence of these vesicles was associated with a discharge of viscid saliva from the mouth, loathing of food, imperfect mastication, suspension of rumination, loss of milk, a tenderness in walking, and general symptoms of febrile action.

The malady was not confined to cattle, but sheep, pigs, and domestic poultry of the gallinaceous tribe were likewise its subjects. By common consent it was designated the cattle epidemic, but has since been scientifically known as *Eczema epizootica*, or popularly as "the mouth and foot disease." It has continued from that time to the present, not proving on the whole a destructive disease to life, but at irregular intervals assuming a severer form than ordinary, more particularly in 1845 and 1852, and leading on these occasions to a great deterioration in the value of the animals affected.

Shortly after the appearance of the eczema, namely, in 1841, pleuro-pneumonia broke out among the cattle, and it, too, has remained down to the present time. It is worthy of a passing remark that neither of these were imported diseases. It was not until several months after pleuro-pneumonia had established itself in the country that an alteration took place in the tariff by which live stock came in free of duty, and up to that time the high rate of duty prevented any importations of foreign cattle or sheep being made. This fact in itself is sufficient to prove that the malady was not imported by foreign cattle; besides which, the parts of the country where it was first observed could not possibly have had any immediate or direct connection with the ports. Pleuro-pneumonia had no sooner gained a footing, than, following the laws of all epizootics, it quickly spread over a great breadth of country, and continued to devastate our herds with almost unmigitated severity for the first few years. It has since taken on rather an enzootic form, and has prevailed mostly in such localities and places where secondary causes are in full operation to predispose animals to its influence; hence its continuance in the ill-ventilated, over-crowded, and badly-drained cow-sheds of the metropolis and other large towns, and on the "cold retentive soils" and undrained farms in the country, especially such as lie in exposed situations.

Besides the special cause, or rather, perhaps, special combination of causes, which give origin to the enzootic form of pleuro-pneumonia, its appearance in a cattle-shed, or on a farm, is frequently traceable to the introduction of newly-purchased animals, who bring the disease in a latent state with them; and which, on its declaring itself, extends by ordinary infection to those with whom they are located. Infection we hold to be one of the chief causes of the continuance of pleuro-pneumonia for so many years among us, as every diseased animal, by virtue of the exhalations given off from its body, becomes a focus of the malady, and a new source, whence the poison, so to speak, is disseminated. The same fatality which marks the progress of pleuro-pneumonia here, attends it everywhere; and throughout the continent it is looked upon as an incurable disease, and dealt with accordingly. Its great fatality arises from the circumstance that the nature of the changes which take place in the lungs is such as immediately to arrest their function as perfect aerifying organs, and soon to destroy, to a greater or less extent, the integrity of their structure. The true pathology of pleuro-pneumonia is among the *questiones vexatæ* of science. In this report we have not immediately to do with this question, still we may observe that the most eminent professors of veterinary medicine throughout Europe hesitate to declare, as some medical men have done, and others also who have probably given but little thought to the subject, that the changes wrought in the lungs are altogether due to inflammatory action.

In Belgium, in France, and in many parts of Italy, the disease is designated *exudative* pleuro-pneumonia—a name which, while it marks a peculiarity in the disease, implies, at the same time, that it differs somewhat in its results from ordinary inflammation of the lungs and their investing membrane, and which is correctly called pleuro-pneumonia. We have no hesitation in giving it as our opinion that the changes which are *originally* effected in the lung tissue can take place otherwist than by inflammatory action. We observe, as the analogue of these changes, that in the advancement of the disease, the interstitial areolar tissue, contiguous to the more affected parts of the organs, becomes primarily choked with *serous* effusion, which, by its pressure upon the air cells and their rete of capillary vessels, obstructs both the admission of air to the cells, and the circulation of the blood through the vessels, and thus leads to an imperfect decarbonisation of the blood, as well as to far more important changes in the fluid itself. Not only, in many diseases, are serous exudations entirely independent of inflammation, but fibrinous are equally so in the opinion of some of the ablest pathologists of the present day. These deposits may result from the vital force of the vessels being impaired by some depressive influence acting on the nervous system, either generally or locally, as well as by some unexplained or ill-understood alteration taking place in the composition of the blood, by the existence within it of morbific animal or vegetable products. The fibrinous depositions in pleuro-pneumonia succeeds the serous, and are probably due to either an alteration in the relative proportion of the component parts of the blood, or an interference with its vitality, brought about by the presence of the special *materies morbi* of the disease, and which may have entered it in the ordinary manner of infection. The abnormal action which commenced in the parenchyma of the lungs extends towards their investing membrane, when, from the nature of this tissue, as well as from the longer existence of the action itself, an augmented fibrinous exudation takes place upon their surface. We regard, therefore, the implication of the pleura as a characteristic of an advanced stage of the malady, and also of a still further deterioration of the blood.

Since the appearance of pleuro-pneumonia no other disease of a fatal character and possessing contagious or epizootic properties has shown itself among our cattle; but in 1847 a very fatal malady broke out among the sheep. This affection was recognised as the small-pox of sheep; and it was ascertained in the most conclusive manner that it had been introduced here by some "Merinos," which had been shipped at Tonning, on the coast of Denmark, and also by some others shipped at about the same time at Hamburgh for the supply of the English market, and in whose systems the disease was incubated. From the free commingling of these foreign sheep with our own breeds in the London Cattle Market, and also from the circumstance that many of them were purchased by farmers as "stock sheep," the small-pox was soon spread over a great tract of country, proving destructive to life in numerous instances to the extent of even 90 per cent.

This state of things was met by legislative enactments with view to arrest the progress of the disease, and happily they proved of essential service in so doing. By the expiration of the third year from the outbreak, scarcely an instance of the disease could be met with in any part of the country, and this notwithstanding tens of thousands of animals were, to our own knowledge, affected in the year succeeding its introduction. From the time of its subsidence in 1850 until now, we have been perfectly exempt from cases of small-pox.

This short historical account of epizootic affections of cattle, in this country, brings us down to the present period, and to the especial subject of this report.

It was during the latter part of the past year that the public mind became much excited by frequent and almost continuous reports that a malady of a most fatal description had shown itself among the cattle on the Continent, and that it was rapidly extending towards those countries whence we received our chief importations. In the early part of the present year the subject assumed so much practical importance that the attention of Parliament was directed to it on two or three different occasions. Her Majesty's Government, it was found, had early given instructions for our Consuls abroad to collect all the information they possibly could in their several localities, and transmit the particulars of their inquiries without delay to the Minister of Foreign Affairs. These despatches were from time to time forwarded by Lord Clarendon to the Council of the Royal Agricultural Society, who also had from the beginning taken the liveliest interest in the matter, and who lost no opportunity of placing the latest information before the country through the weekly publication of their proceedings. The official documents, however, in no way tended to allay public apprehensions, but rather, on the contrary, to increase them, as it was distinctly stated that the "murrain" was rapidly making its way westward from the countries where it had been first observed, and that it would ere long be introduced here unless the greatest caution was exercised in regulating our supply of foreign cattle; and that even then it was more than probable the disease would come in, it being said that it could be carried from place to place by skins, hoofs, or horns, or indeed anything which had been exposed to the infection by being brought near to the diseased animals.

Notwithstanding the great amount of information which was supplied by our Consuls, but very little of a satisfactory kind could be obtained with reference to the true pathology of the disease. The Council of the Royal Agricultural Society therefore felt that under such circumstances as these some more decisive step should be taken; and this opinion found a ready response in the other two national Agricultural Societies of Scotland and Ireland. At this juncture a communication was received from the Royal Agricultural Improvement Society of Ireland, suggesting "that it would be desirable for the three agricultural societies of the United Kingdom to join in the common object of despatching abroad a special veterinary inspector, for the purpose of ascertaining the exact nature of the contagious typhus."

At a meeting of the Council, held on the 1st of April, some further communications were read from Mr. Hall Maxwell, C.B., Secretary of the Highland and Agricultural Society of Scotland, and from Captain Croker, Secretary of the Royal Agricultural Improvement Society of Ireland, expressing their willingness to concur with the Royal Agricultural Society in making arrangements for despatching a veterinary inspector to the districts abroad where the cattle murrain was at present raging. The Council thereupon agreed to the following resolution:—

"That it is expedient to send a competent veterinary professor to examine into the nature of the cattle murrain on the Continent. That the Society gladly accepts the co-operation of the Highland and Agricultural Society of Scotland and the Royal Agricultural Improvement Society of Ireland in this step. The Society ventures to recommend that Professor Simonds, of the Royal Veterinary College, be commissioned to this task. That he be empowered to take with him a German veterinary surgeon, established in London, quite competent for the business, and who would smooth the difficulties of the German language. It is supposed that about three weeks would be required for a satisfactory examination. That the Highland and Agricultural Society of Scotland be informed that the Royal Agricultural Improvement Society of Ireland propose to share the expense of this mission with the Royal Agricultural Society of England; and that they be asked to join in the same manner."

It is scarcely necessary to say that the national societies of Scotland and Ireland most readily consented to the proposition contained in this resolution; and on the Government being informed of the step about to be taken, Lord Clarendon kindly forwarded the subjoined letter of introduction to the British Consuls to me, through the Secretary of the Society, accompanied with the following communication:—

"Foreign Office, April 4, 1857.

"SIR,—I am directed by the Earl of Clarendon to acknowledge the receipt of your letter of the 2nd instant, acquainting his Lordship with the intention of the Council of the Royal Agricultural Society of England, in conjunction with the Societies of Scotland and Ireland, to send Professor Simonds to those districts abroad where the disease among cattle is at present raging; and I am to enclose a letter which has been addressed, by Lord Clarendon's direction, to the British consular agents in Northern and Central Europe, instructing them to afford to Professor Simonds all the assistance in their power in carrying out the objects of his mission.

"I am, sir,

"Your most obedient, humble servant,

"James Hudson, Esq." "E. HAMMOND.

(Enclosure.)

"Foreign Office, April 4, 1857.

"SIR,—I am directed by the Earl of Clarendon to acquaint you that the Council of the Royal Agricultural Society of this country have notified to his lordship their intention, in conjunction with the Agricultural Societies of Scotland and Ireland, to send a veterinary professor to the districts abroad where the disease among cattle is at present raging, and that the Committee have selected Professor Simonds for this service. I am, therefore, to instruct you, in the event of Professor Simonds visiting any part of your district in the course of his mission, to show him every attention, and to afford him all the assistance in your power in carrying out the objects of the societies by whom he has been appointed—I am, sir,

"Your most obedient humble servant,

"E. HAMMOND

"To the British Consular Agents in Northern and Central Europe."

The first step, according to my instructions, being to secure the services of a veterinary surgeon familiar with the German language, I at once called on Mr. Wm. Ernes, M.R.C.V.S., a gentleman eminently fitted for the task; and who, besides being a native of Belgium, had had the great advantage of travelling almost throughout Europe, thus becoming practically acquainted with most of the foreign languages. Mr. Ernes had also received an English medical education, and his tastes were in full accordance with the objects of the mission.

Having secured his co-operation, we left London for Belgium on the morning of April 9th, and arrived the same evening at Ghent.

We deemed it expedient to ascertain, with as little delay as possible, the health of the cattle in those countries whence we were receiving our daily supplies, and also

the details of the system which prevailed with regard to the cattle trade, together with the particulars relating to the shipment of animals to England. This part of our mission was the more pressing as the recent Order in Council, prohibiting the importation into the United Kingdom of "cattle or of horns, hoofs, or hides, from those territories of Russia, Prussia, or Mecklenburgh-Schwerin, which lie in the Gulf of Finland, or between the Gulf and the city of Lübeck" might be found to require an immediate extension to other countries, or possibly we might ascertain that a relaxation of it could be made without the incurrence of a greater risk of the disease being introduced. We therefore commence our inquiries in

BELGIUM.

Our investigations here fully confirmed the statement made by Lord Howard de Walden, her Majesty's Ambassador at Brussels, in his despatch to Lord Clarendon, dated March 20th, 1857, that this country was perfectly free from the rinderpest. We found that eczema epizootica prevailed to some extent, but not in a serious form, and that pleuro-pneumonia also existed in several parts of the kingdom. Rinderpest had not shown itself to an extent to create much solicitude since the Seven Year's War, during which time it destroyed vast numbers of cattle. From 1813 to 1815 some cases occurred in the district between Namur and Luxemberg, and which are said to have depended upon the passage of the Austrian army into France. The route taken by the army was south of the Belgian frontier, and near to the places in question; and it appears that along its whole course the disease was manifested to a greater or less extent on either side of the military road. It is also said that the cattle belonging to the Prussian army being healthy, no disease followed its course through the country, and thus a great part of Belgium escaped the pest; the measures of sanitary police confining it chiefly to the neighbourhood of Namur, and the districts in which it had manifested itself.

We refrain from commenting on these facts in this place, as hereafter we shall have to call attention to the freedom of continental states in general from the disease, unless infected cattle, or such as have been exposed to the contagious influence of the malady, are introduced therein.

At Ghent we visited a cattle fair which was held the day after our arrival, and had thus an opportunity of observing the general state and condition of animals brought from all parts of the kingdom, and which proved to be most satisfactory. From the cattle-dealers we learned that no difficulties existed in the way of the passage of cattle to or fro over the frontier, so long as they are healthy, but that restrictions would be rigidly enforced on the breaking out of a contagious disease. Lord Howard de Walden writes that "no law exists under which diseased cattle can be excluded at the *frontier;* a project of law, with a view to such sanitary precaution, was presented to the Chambers two years ago, but was rejected; and therefore the only resource lies in the activity of the burgomasters in frontier localities, by enforcing the general regulations in regard to animals while within the range of their jurisdiction."

Pleuro-pneumonia has prevailed rather in a sporadic than an epizootic form for the last two years, and an equal number of cases are said to have occurred in places where the feeding and general management of the animals are unexceptionable, as in those where the opposite state of things obtains, but that, under the latter-named circumstances, the disease has assumed a more fatal character. All animals which are supposed to be affected by this disease have to be reported by the proprietors, and if, on examination by the Governmental veterinary surgeon, they are found to be the subjects of it, then an order is given for them to be killed. The skin, horns, and other integumental parts are used, but the flesh is buried as a rule, in accordance with the regulation of the Government, who pay a proportionate amount of the value of the animal, and generally to the extent of one-third.

It appears, however, that this regulation is sometimes evaded, and that the carcases of such animals occasionally find their way into the meat market, but no instance of injury done to persons eating such flesh is known to have occurred. Many animals also are not officially reported, as the proprietor either sells them for slaughtering or has them killed unknown to the authorities. Should this, however, become known, the animal is seized, and disposed of as the Government sees fit, and a fine is also inflicted on the offender. Upon the whole, the laws of the sanitary police are so strictly enforced, that in the event of the rinderpest extending into Belgium, it seems scarcely possible for animals which *had even been exposed* to its infection to be exported from the country.

At Antwerp, we ascertained that the chief exports of animals to England from thence are calves, and that the major part of the cows and oxen which are fatted for the market are sent into France, where at this time a better price is obtained for them than in England. The calves are purchased of the farmers in different parts of Belgium by commissioned agents, who collect them together for shipment from Antwerp, but some of the oxen come direct from Holland. The proportionate amount of oxen to calves which are exported is shown by a return furnished by MM. Vandenbergh for the year 1856. The MM. Vandenbergh are the largest shippers of cattle to England; and although a few animals are sent over by other companies, they are in about the same proportion. The return shows that 2,020 calves were forwarded here in the year, but only 10 oxen.

HOLLAND.

As this country sends our principal supply of foreign cattle and sheep, it became the more important to ascertain their freedom, or otherwise, from contagious diseases. With the exception of pleuro-pneumonia and eczema, no other affection prevails among the cattle. Rinderpest has had no existence for upwards of forty years, and is unknown even to the veterinary profession, except by name. The parts of the country most affected with pleuro-pneumonia at this time are North Holland and Friesland.

By a statistical return from forty-three villages in North Holland and Friesland, it is shown that only eight of them have been comparatively free from pleuro-pneumonia, and in these but very few cattle are kept. In the villages where the disease has prevailed, about a fifth part only of the cattle-owners have escaped upon the whole, but in many every proprietor has had his herd affected. In the first quarter of the present year the official returns show a total loss of 3,655 head of cattle, of which 1,502 died, and 2,153 were killed by order of the authorities, which gives an average loss of about 281 per week.

We are not surprised at the great extent of these losses, judging from what we saw of the secondary causes of epizootics in operation in the vicinity of Rotterdam. The cattle are often crowded into houses so thickly, that to pass between them is almost an impossibility. The form and size of the building also will frequently allow of a passage only to be made by a person along its centre, where the heads of the animals nearly meet over their feeding troughs, while the height of it is generally insufficient to stand upright in. No windows exist in many of these sheds, nor any other inlet for light and

air, except the door. The heat is almost suffocating, and the stench abominable. In such unwholesome and pest-breeding places as these the cattle, often to the extent of forty or fifty in a shed, are kept for weeks together to be fatted for the market, by being fed chiefly on the wash and grains which come from the distilleries.

The cattle which are sent from Friesland are shipped at Harlingen direct for England, and the numbers put on board there are fully six times greater than at Amsterdam. Friesland is one of the great cattle districts of Holland, and supplies not only the English market with many animals, but other countries likewise. She therefore receives no imports, nor does it appear that any of the vessels conveying cattle from the ports of the Elbe or the Weser, or from any part of the coast of Holstein, ever touch at the Dutch ports, so that a contagious malady like rinderpest, existing in Holstein or in the countries watered by those rivers, would have to make its entrance by way of the land into Holland.

No restrictions are put upon the cattle trade with reference to the bringing of animals over the frontier, but all importations of the kind would be immediately prohibited on the appearance of the disease in question in any neighbouring states. The prices obtained for cattle in the English market are not viewed as being sufficiently remunerative just now by the Dutch feeders, and hence the diminished numbers sent here. When the contrary state of things prevailed, many animals were purchased in Prussia by the dealers, and forwarded to the different ports of Holland for exportation; and not a few, it is said, came even from Switzerland down the Rhine for the same purpose. These facts show that it is possible for a disease of a malignant kind, which is incubated in the system of an animal for ten days or a fortnight, to be introduced into England from other countries *via* Holland: and, also, how necessary it is that we should be acquainted with what is passing on the continent with regard to diseases in general as affecting cattle, and particularly if belonging to the class which forms the subject of this report.

The continuance of a well-ordered and rigid system of inspection of imported animals on our part will, however do much to protect us, and that not merely by its leading to the detection of diseased animals on their arrival, but by the effect which it will have upon the export trade of foreign countries. Proof of this is given by the circumstance that last year, when it became known that our Customs' inspectors had received orders to be particularly strict in the examinations of cattle, the General Steam Navigation Company of Rotterdam, unwilling to take the responsibility of the probable rejection of animals committed to their care, appointed a veterinary surgeon to examine them when put on board their boats. This company brings by far the largest proportion of cattle to England, and although this precautionary measure was not adopted by other shipping companies, they nevertheless declared their intention of having recourse to it, and only refrained from so doing, because of the great diminution which took place in the number of the animals which were shipped. The system of examination was kept in force for about three months, when also, and from the same cause, the General Steam Navigation Company discontinued it. The returns of these examinations, together with the results were regularly transmitted to the British Consul. Should the prices again rise in England to an extent which would, in the opinion of the cattle feeders, justify them in sending us more animals, then there cannot be a doubt of the re-establishment of this system of inspection.

No duty is chargeable on animals imported into Holland, but an *export* one has to be paid, and which amounts in English money to about the following rate per head, namely, oxen, 10d., calves 2d., sheep 2d., lambs 1d., pigs 1d., with an additional duty of thirteen *per cent.* on the gross sum.

Although Holland rears immense numbers of cattle, she, for her great export trade in these animals, becomes an importing country for hides, receiving her chief supply of these from Java and Buenos Ayres, with some England, but none from Russia, so that all fear of our introduction of contagious diseases through the means of skins may cease, in so far as Holland is concerned.

Our investigations led us to visit the cattle feeders, and among others we saw Mynheer A. Poot, who resides within a few miles of Rotterdam. M. Poot ships upon an average 600 animals a-year. He informed us that no disease had prevailed in his sheds since February last, prior to which time he had several cases of pleuro-pneumonia. He appeared to be an entire stranger to any other contagious disease, and said that, in the event of an affection like rinderpest breaking out among his stock, a *cordon* would be immediately placed around the farm by the *local* authorities, and that he should be compelled to slaughter the diseased animals and bury them with their skins on in quick lime. In his opinion it would be an impossibility to export any portion of their carcases to England, even if attempts were made to do so, in consequence of the strictness with which the police sanitary regulations are carried out. He adduced as an instance that on the first breaking out of pleuro-pneumonia in 1829, and before experience had shown that the flesh could safely be used for food, he and others had to kill the affected cattle and bury them entire, with a view to prevent injury being done to the people, as well as to limit the spread of the malady.

On the question of our Government ordering all imported animals to be slaughtered on their arrival in the docks, and their carcases sent to the meat market, M. Poot considered that such a step would be tantamount to the stopping of the importations entirely. The boats very rarely, if indeed at any time, are freighted with cattle all belonging to the same person: the cargo is therefore mostly comprised of animals the property of several individuals, and identity of each particular animal, which is necessary for the purposes of trade, could scarcely be made under such circumstances; besides, he said, a necessity would be created for an immediate sale of the meat to the injury of the interests of the persons sending the animals. He was equally opposed to the establishment of a quarantine, and was of opinion that it could never be carried into practice, and England continue to receive full supplies of foreign cattle.

The system at present adopted is for various feeders to consign their cattle to salesmen in the London market, who, as in the home trade, charge a commission on the sales they effect. As no animals are brought into Rotterdam coastways for re-shipment, all consequently have to pass through the town to reach the vessels, so that they are thus subjected to the general inspection of the local authorities, regulations existing to prevent diseased animals from entering into this and the other towns of Holland. Besides the security thus afforded it is clearly not in accordance with the interests of the exporters to put diseased cattle on board, as it is impossible for them to bear up against the fatigue of a sea-voyage, or to be on their arrival here in a fit state to pass the scrutiny of our Customs inspectors.

The cattle which are fatted either for the Dutch markets or for exportation are purchased at the different fairs and markets in the country, and are for the most part reared in Friesland and Guelderland, scarcely any being brought in from other countries

Upon the whole, notwithstanding the dangers we have pointed out, the system which prevails generally with regard to the cattle trade, and the additional regulations

which would be enforced did necessity arise, appear to offer a fair amount of security against the introduction of a new cattle pest from Holland.

Westphalia and Hanover.

These countries are entirely free from Rinderpest, and have been so for upwards of forty years; and, besides which, very little disease of any kind was found to be prevalent among the cattle. The laws which are enforced with regard to contagious diseases, are analogous to those which are generally adopted upon the Continent, but differ a little in some of their details.

Pleuro-pneumonia was said by the late M. Hausmann, Professor of the Veterinary School, to have been first observed in Hanover as early as 1807. This disease has existed with some few intervals, and with more or less severity, down to the present day. Of late years the animals attacked have been so few as not to create any great solicitude on the part of the Government. Precautionary measures are, however, adopted on the frontier with regard to cattle coming from Holland, which are made to undergo a quarantine, and none are allowed to enter from Holstein, unless they are certified to be in a state of perfect health.

Veterinary surgeons are bound to give notice of all cases of contagious disease which they may meet with in their practice, and proprietors also are required to report the appearance of pleuro-pneumonia or allied affections among their cattle. No animal, although seemingly in perfect health, if it has been living with others affected with pleuro-pneumonia, can be pastured or driven on roads so as to come within two hundred yards of other cattle; nor can the owner dispose of any of his herd under such circumstances until it is certified by the department veterinary surgeon that all the animals are perfectly free from the disease. The period of time which is allowed to elapse after the passing away of the malady and the selling of the cattle is left to the discretion of the veterinary surgeon. A proprietor can place his animals under medical treatment if he sees fit, or he is at liberty to slaughter them and send them to the meat market. The flesh of those affected with pleuro-pneumonia, even in its advanced stages, is not unfrequently sold, as in England, by the inferior class of butchers.

A regulation exists with regard to the disease of glanders, which, although it does not belong to the special object of this report, may, nevertheless, be mentioned. Horses affected with this malady are not only prevented being sold or exposed for sale, but the owner is compelled to have them killed; and he is not allowed, under the pain of a heavy penalty, to sell any other horse out of his establishment, or even to place any one of them in stables belonging to other persons, for six months after the death of the affected animal.

M. Hausmann, Veterinary Surgeon to his Majesty the King of Hanover, informed us that a conviction had very recently taken place under this law, where a carrier was heavily fined for putting his horses, which had been with a glandered animal, into a stable at a public inn in the town of Hanover, on the occasion of his coming to the place on the market day.

Hamburg.

This, as the chief port of the Elbe, receives a considerable number of cattle from the surrounding districts for exportation to England, and large quantities of hides are also sent from hence. Some diminution in the amount of cattle which of late has been shipped at Hamburg has taken place, and from the same cause which is assigned by the exporters from Holland, namely, that the price obtained in the English markets is not sufficiently remunerative when compared with that which can be procured at home.

The cattle come chiefly from the distillers, sugar refiners, and farmers in the town and territory of Hamburg, and the adjoining duchies of Holstein and Lauenburg. They are usually sent first to the market at Hamburg, and if not sold are exported to England. An inspection of them is regularly made in the market by a duly appointed veterinary surgeon; besides which they are prevented entering the town unless found to be in a healthy state. These regulations afford us a certain amount of security against the importation of diseased animals from this port. The system of inspection has been in operation from the commencement of the recent outbreak of pleuro-pneumonia in Holstein; but it has been particularly observed since September, 1856, when the following proclamation was made by the Senator of the Marshlands of the territory of Hamburg—

Proclamation.

It having been communicated to the Senator for the district of the Marshlands that in several parts of the Duchy of Holstein a pulmonary disease has again broken out among the cattle; in order to prevent the introduction of this dangerous malady, it is hereby ordered that for the present no cattle can be brought into the district of the Marshlands from the duchies of Holstein and Lauenburg without a certificate from the proper local authorities, stating that, at the places from whence the same may come, no infectious disease prevails among the cattle, and this under a penalty of 50 thalers for every case of contravention.

The whole of the bailiffs and subordinates are hereby required particularly to attend to this order, and obtain observance of the same, and denounce to the authorities of the Marshlands all who may disobey or attempt to disobey the same.

(Signed) Arning, Dr.
Senator for the Marshlands.

Hamburg, 19th September, 1856.

No cattle intended for the English market are brought into Hamburg by the ships from Tonning or the other ports on the coast of Denmark, but they go direct to England; nor are many conveyed there for this purpose by means of the navigation of the Elbe from Central Germany. "The Order in Council," at the time our visit in April, did not appear to be understood by the exporters of cattle as to the intention of the Government with regard to this port; and they refrained at first from shipping cattle, although Hamburgh was not named in the prohibition, for fear lest on their arrival in England they should be seized by the Commissioners of Customs.

We were informed by Colonel Hodges, Consul-General at Hamburg, that a similar doubt existed with regard to hides, and, further, that the order would be inoperative for good, presuming that the seeds of a contagious disease could be conveyed by these articles of commerce so long as Hamburg, as the port of the Elbe, and Bremen, as the port of the Weser, were left open, as large quantities of these commodities come down those rivers. The hides are collected from out of various countries, and it is impossible to trace them to their original source. The merchants of Hamburg, however, continued to export hides, first making a declaration before the consul that they did not come from Lubeck or any of the Baltic ports. The consul upon this certified that such declaration had been made, and thus left our Commissioners of Customs to deal with the question as they might see fit. Should the necessity unfortunately arise to prohibit the importation of cattle, hides, hoofs, &c., from fear of introducing a contagious disease, such as the rinderpest, then not only must Bremen and Hamburg be named in the order, but Tonning also, as the port of the Eider, as this place has direct water communication with the port of Kiel on the Baltic, from which place hides, hoofs, &c., can readily be conveyed.

Little fear, however, need be entertained of the introduction of the disease from Denmark by means of any

cattle which she might receive from the Baltic ports. The difficulties in the way of a *direct* trade of this kind are too great for it to be carried on with facility or advantage. Such cattle would have to make the port of Kiel, and be then disembarked, in order to be placed on the vessels navigating the canal which connects Kiel with the Eider, and on reaching Tonning be again re-embarked on vessels bound for England.

DENMARK, SCHLESWIG, AND HOLSTEIN.

In September last it was officially communicated to the Government by Vice-Consul Blackwell of Lubeck, that "the *steppe murrain of Russia had made its way into Holstein*, having passed through Poland, Prussia, and Mecklenburg." We ascertained, however, that this disease had no existence in this part of Europe since the occasion of its last general outbreak in 1813. It is also recorded that up to that time the affection had not prevailed in the duchies since 1774 to 1781, when 150,000 head of cattle are said to have perished.

Pleuro-pneumonia is rife in Holstein, particularly in the neighbourhood of Altona, where an active cattle trade is carried on. The malady is said originally to have appeared here in 1842, or nearly about the same time it was first observed in England. At the commencement of 1843, Herr Rottger, district veterinary surgeon of Altona, received orders from the Danish Government to watch the progress of the disease. No active means to limit its extension were, however, had recourse to until 1845, when the Government sent Professor Witt of Copenhagen, to investigate the matter. Professor Witt and Herr Rottger, with a surgeon and the Government veterinary surgeon of Hamburg, formed a sanitary commission of inquiry. The commission came to the conclusion that the disease was highly contagious, and recommended the Government to adopt the most stringent measures of prevention. These consist in chief of—

a. Sequestration of the places where the disease is found to exist.

b. The immediate slaughter of the infected animals.

c. The killing of the whole herd upon the occurrence of fresh cases.

d. The burial of the diseased cattle with their skins on, cut in such a manner as to prevent their being surreptitiously disposed of, and the sprinkling the body over with chloride of lime.

The indemnity consists in the Government paying two-thirds of the value of the diseased animals, and the full value of the healthy, the loss to the treasury being partly provided for by the Government selling by public auction the carcases of the animals which are free from disease.

For the carrying out of these regulations, it is ordered among other things that every proprietor of cattle shall, upon the outbreak of a disease which seems to possess some unusual features, give notice to the district veterinary surgeon, or be subjected to a fine varying from fifty to a hundred thalers. The veterinary surgeon has to report the result of his examination to the police, and if it should prove that the malady is a contagious one, then the regulations are strictly enforced. The animals are valued on the part of the Government, and branded on the horns for the purpose of identity. Should no other cases occur after the diseased animals are killed, then a proprietor is prevented selling any of those which had been exposed to the contagion, and which bear the Government stamp, in a less period of time than six months, and only then with a certificate from the veterinary surgeon that they are free from disease.

The adoption of these severe measures led, it is believed, to the nearly total extinction of pleuro pneumonia in two or three years. In 1847, however, it again prevailed in Holstein, also commencing, it is said, in the neighbourhood of Altona. In 1849 and 1851 other outbreaks occurred, the disease extending on the latter occasion into Schleswig and Denmark proper, but was quickly suppressed by the severity with which the law was executed.

The outbreak from which the country is at present suffering took place in the spring of 1856. It is attributed to the circumstance of two gentlemen of Hamburg purchasing in Hungary 180 oxen, and sending them to graze on the islands and marshlands of the Elbe. The disease manifested itself in these animals, and from them it was communicated to some cows which were sent daily from the town of Hamburg to graze in the same pastures, and was thus spread over the territory and the adjacent portions of Holstein. This called for the re-adoption of the preventive measures previously alluded to, and which are still in operation in the Duchies, but modified to some considerable extent in the town and territory of Hamburg.

The almost simultaneous appearance of pleuro-pneumonia in Mecklenburg, which is said to have depended on the introduction of some cattle from Bavaria, together with its existence in several of the German States, led the Government to issue the following order with reference to the importation of cattle into Holstein and Lauenburg.

Copenhagen, June 18, 1856.

PROCLAMATION for the DUCHIES of HOLSTEIN and LAUENBURG, in reference to the IMPORTATION of HORNED CATTLE from abroad.

Whereas, according to official information, the pulmonary epidemic has recently shown itself again in horned cattle in several German States, the importation of horned cattle from abroad will not, until further notice, be permitted into the duchies of Holstein and Lauenburg, unless satisfactory certificates, issued by authority, be handed in at the same time, stating the place from whence the cattle have been brought, and that in such place no signs of the pulmonary epidemic have appeared for more than six months, the cattle being therein described as accurately as possible.

The above is hereby made known for the information and guidance of those who receive it; and at the same time the police authorities are especially directed to see the strict observance of the above order.

Royal Ministerial Department for the Duchies of Holstein and Lauenburg, 9th June, 1856.

(Signed) V. SCHEELE.
G. HARBOU.

Pleuro-pneumonia, however, continued to prevail in Holstein, despite all measures precautionary or otherwise, which were had recourse to, and this led the Minister to issue new regulations during last year, to stay if possible its further progress. It was thereupon ordered that "*all estates* (farms) *in which cases of pulmonary disease have occurred within the last six months, are to be closed, and no removal of cattle from such estates is to be permitted. The cattle are to remain as much as possible in the same stalls, and only to be removed to the pasture grounds of the owners, which are to be fenced round to the exclusion of all other cattle, as it is deemed necessary to remove cattle from their infected stalls to purer air.*"

In July, 1856, SCHLESWIG placed the importations into her territory from Holstein under restrictions; but as these also proved to be insufficient, the Minister of this Duchy, in March of the present year, forbade the importations entirely.

In August, 1856, Denmark, by the Minister of the Interior, likewise ordered that no cattle would be permitted to enter the kingdom from Holstein, unless they were accompanied by a certificate of a veterinary surgeon, stating that they were in good health when exported, and also by the certificate of a magistrate, that the district from which they came was free from disease. And in September following proclamation was made to

a similar effect by "the Senator of the District of the Marshlands of Hamburg," a copy of which has been given above.

This succinct history of the proceedings of foreign governments enables us to trace to their probable origin those restrictive laws which have created so great solicitude in England. We could hardly have supposed that such severe measures would have had the support of scientific men, and more especially in their exclusive application to a disease, whether contagious or not, the antecedents of whose history show that it often passes from country to country as an ordinary epizootic affection.

Without wishing to animadvert on the opinions of others, we hold that an equal amount of good would attend measures far less stringent; and, if this be so, then a positive injury is inflicted on the country where they are enacted. Take, as one illustration, the quantity of food which is lost to the people by the burying of animals in whose system the malady has made but little progress. We are exceedingly jealous lest any observation of ours should be supposed to give encouragement to the sale of diseased meat; but, after fifteen years' experience of pleuro-pneumonia in this country, and of the sale of the carcases of animals, the subject of it, we do not hesitate to state that the flesh is fitted for food in the early stage of the affection.

The surprise in the continuance of the system of killing and burying bovine animals becomes the greater when we see it adopted in a country where the sale of horseflesh, as an article of food, is both legalized and encouraged by the Government. In Altona we passed by the shop of one of these horse-butchers, and saw exposed for sale part of the hind-quarters, and sundry pieces of flesh of a horse, and also the liver and kidneys of the animal. We were tempted to walk in, when we were informed by the proprietor that there were four other establishments of the same kind in the town, but that his was "the original one." He said that so ready a sale was found for the meat that it was with great difficulty he could procure horses enough for his customers. The price ranged from about 2d. to 3d. per lb. English money, and it appeared that the meat was often bought by persons who could not be properly said to belong to the lower classes. We were invited to see the establishment, and visited the slaughter-house and stable. In the former, besides more meat, was hanging the lower part of the fore leg, with the foot of the animal last slaughtered, which had been put aside for the inspection of the police; and in the latter were standing two aged and worn-out horses waiting their turn to be led to the stake.

These butcheries are licensed by the Government, and are under the supervision of the police. Notice has to be given before a horse can be killed, when the veterinary surgeon of the department attends and examines the animal, and, if found to be free from constitutional disease, notwithstanding it may be incapacitated for work from lameness or other defect, he certifies to that effect, and for the sake of identity brands the animal on its hoof. Within a given time the animal must be killed, and its leg and foot produced for the inspection and satisfaction of the police.

Sweden and Norway.

We find by a perusal of official documents which have been placed at our disposal, that the fear of the introduction of pleuro-pneumonia from Holstein led the government of Sweden to interdict the importation of cattle from that duchy in August, 1856, unless accompanied by satisfactory certificates of health. The importation also of cattle from England and Scotland into Sweden was prohibited in the same month. These precautionary measures on the part of Sweden were quickly followed by the promulgation of similar ones by the Government of Norway, being in each case evidently founded on the belief that contagion is the chief, if not the only cause of the spread of pleuro-pneumonia.

Lubeck.

From the circumstance that her Majesty's Government, by "the Order in Council" of April 2nd, saw fit to prohibit the importation into England "of cattle, horns, hoofs, raw or wet hides or skins of cattle, which shall come from, or shall have been at any place within the territories of the free city of Lübeck," as well as other places named in the said order, it was to be expected that the so-called "steppe murrain" (rinderpest) would be found to be prevailing among the cattle at Lübeck. We were informed, however, and immediately on our arrival, that no such disease existed; and ample opportunities were afforded us of subsequently confirming the correctness of this statement. Indeed, rinderpest has never shown itself in the territory since 1813-15, when by the movement of troops throughout Europe it prevailed rather extensively here and also in most countries of the continent.

The precautionary measures which were taken in the spring of 1856, by the Senate of Lübeck, *had especial reference to pleuro-pneumonia*, which disease had somewhat suddenly made its appearance in the adjoining Duchies of Mecklenburg-Schwerin and Mecklenburg-Strelitz. Some doubt, however, was felt in this country as to whether the "steppe murrain" had not found its way thence from Prussia; and this was considerably added to by the official reports of Mr. J. A. Blackwell, who up to the beginning of the present year was British Vice-Consul at Lübeck.

In two despatches dated respectively May 17th and 30th, 1856, Mr. Blackwell informed her Majesty's Government, through the Consul-General at Hamburg, that a contagious pulmonary disease or murrain had broken out among the cattle in Mecklenburgh; and after giving the particulars of the precautionary measures adopted by the Lübeck authorities to prevent its entrance into their territories, he states that he had consulted several of the best German authors on the contagious maladies of cattle, and found that they made a distinction between "rinderpest and pulmonary murrain;" but he adds, "*both are equally contagious and almost equally fatal, and in a sanitary point of view may in fact be regarded as identical.*"

Mr. Blackwell next gives, in the despatch of May 30th, an epitome of the works in question, and under the heading of the STEPPE MURRAIN, he says that it has been calculated that during the last century alone this murrain carried off 28,000,000 head of cattle in Germany; and in the whole of Europe, including Russia, but exclusive of Siberia and Tartary, upwards of 200,000,000;" and that "*although the disease which has broken out among the horned cattle in Mecklenburg seems to be regarded as the pulmonary murrain' pleuro-pneumonia, "it may perhaps be the real steppe murrain, which is now raging in Poland to a fearful extent, notwithstanding the stringent measures that have been adopted by the Russian Government for putting a stop to it.*"

In a despatch dated September 17th, the same gentleman reports that *the murrain* had extended to Holstein, and that in consequence of this the regulations of the Lübeck Government were enforced with regard to that huchy, as well as Mecklenburg. He concludes his communication by observing that, "*as this highly contagious murrain has spread from the steppes of South Russia, through Poland, Prussia, and Mecklenburg to Holstein, to a district from which the English market is supplied with cattle, I must beg leave to call the attention of her Majesty's*

Government to my Report of its origin, progress, treatment, symptoms, &c., transmitted on the 30th of May last."

These statements could not fail to add to the alarm which was originally felt in this country; and when it is considered that for several months afterwards scarcely a week elapsed without intelligence reaching us that "the cattle murrain" was spreading, the surprise becomes the greater rather than otherwise, that some measures of a preventive nature were not earlier adopted by her Majesty's Government. It is true that the reports from other British consuls did not fully bear out Mr. Blackwell's statements, but still nothing satisfactory could be learned of the true nature of the malady; and up to the time of the three National Agricultural Societies determining on sending a commission to investigate the subject, the English public were left in a state of uncertainty and doubt.

In October, 1856, we find that the restrictions against the entrance of cattle into Lübeck from Mecklenburg were removed, as the disease appeared to have ceased there; but they were again enforced in February following, as the malady had reappeared, and on our arrival they were still in full operation.

The regulations which had been enforced by the Senate to guard against the introduction of contagious diseases are as follows. They have been established for several years, and are only modified from time to time, according to the places in which such diseases are known to prevail.

"1. Every owner of cattle is required, in case any disease should break out among the same, which leaves no doubt of its contagious nature, to separate the diseased from the other cattle.

"*a.* The special symptoms of *lungenseuche* (pleuro-pneumonia) are a husky cough, which is increased, particularly after the cattle have been watered or moved about, less inclination for food, indifference as to chewing the cud, dulness of the hair, and its rough appearance in particular places, and fever after these symptoms have continued for some time.

"2. On the appearance of this disease, or even in cases when it is suspected to exist, the owners of cattle are required, under a penalty of a fine of 20 dollars (about £3 10s.) to give immediate notice to the chief of the police, or to the bailiff, at Travemunde, who will take the necessary steps to arrest the progress of the disease.

"3. The bringing in of cattle into the Lübeck territory from the Grand Duchies of Mecklenburg-Schwerin and Mecklenburg-Strelitz shall only be permitted when the cattle are accompanied by satisfactory certificates of their being free from disease.

"4. All veterinary surgeons are directed, in case this disease should break out within the Lübeck territory, to adopt the necessary sanitary precautions according to the instructions of the police. The directions of the veterinary surgeons are implicitly to be obeyed under penalty of heavy fines and imprisonment.

"5. Finally, all police-officers, bailiffs, and gens-d'armes are hereby directed to give notice to the respective police-offices in case any horned cattle should be attacked with the pulmonary disease, or even in cases where it is suspected to exist.

"Given at Lübeck in the Assembly of the Senate, this 14th day of May, 1856. (Signed)

"C. Th. Overbeck, Dr., Secretary."

Besides these measures of precaution, special instructions are issued for the guidance of veterinary surgeons when the disease has entered the territory. These are—

"1. That, on the appearance of pleuro-pneumonia, immediate notice should be given to the police authorities.

"2. That the affected cattle are to be forthwith separated from the healthy, and removed to a distance. If they are put to grass, the meadows must be divided by good fences, and must be at the least five hundred paces distant from any in which other cattle are kept.

"3. That the persons who tend cattle are to be directed to note carefully the feeding and ruminating of the animals, and, on the slightest indication of disturbed health, to have them professionally examined.

"4. That an inspector, duly conversant with disease, is to be specially appointed to attend the sick cattle; and that without his permission no animal is to be returned to those which are healthy.

"5. That all animals which die are to be buried five feet deep, and covered over with compact earth; that the burial-places are to be not less distant than eight hundred paces from any road or paths travelled by cattle, and that they are afterwards to be surrounded by a strong fence or a ditch.

"6. That the diseased cattle are only to be driven in particular roads; that the stables in which they were placed when attacked are to be carefully cleaned, and the manure to be covered over with earth.

"7. That none but medical officers are to make *post-mortem* examinations, and these only by permission of the police authorities; and that no part of the carcase is to be taken away or used, with the exception of the skin.

"8. That for the removal of the dead animals special vehicles are to be provided; and these are to be kept in proper places, and not used for any other purpose. Persons attending upon the sick cattle, or coming in contact with them or with the dead, are not to go near healthy animals, and are to take care that all tools or utensils they may have used are properly cleaned.

"9. That no manure or fodder is to be sold from off an infected farm.

"10. That no animal, however slightly affected, is to be killed for food. Great vigilance must be used in respect to this order.

"11. That, after the disappearance of the disease from a commune or farm for a period of *eight* weeks, it is to be considered as being free from the malady; but that for *four* weeks longer the proprietor is not to sell any cattle or other forbidden things from off the place."

It does not appear that any law is in operation to prevent the importation into the territory from Russia or other countries, of skins, horns, hoofs, or tallow; but we were informed by M. Tollhausen, the French Consul, and who was acting also *pro tem.* as British Vice-Consul, that the official returns show that from 6,000 to 8,000 only of dry hides annually enter the port of Lübeck from Russia, for transit inland; while from Mecklenburg and the surrounding countries 80,000 skins are received. These are mostly either salted or fresh, and as such are too heavy for transit to a distance, besides being otherwise unfitted for such a purpose: they are, therefore, further prepared and dried in Lübeck, and then sent onwards to Belgium, Rhenish Prussia, &c., and up the Rhine even as far as Switzerland.

No exports of cattle take place from Lübeck by means of the shipping, nor are any imported in this manner from the Baltic or elsewhere, the supply which is needed being sent over the frontier from the surrounding duchies. Besides this, we could not ascertain that any cattle have ever been shipped for England from any of the Baltic ports. The difficulties attending such a voyage, and the time it would occupy, are sufficient barriers against a trade of this description being carried on, even if no facilities existed for the transit of cattle inland.

Young stock, however, to the amount, it is said, of 50,000 a year, pass through the territory of Lübeck, from Holstein into Mecklenburg, for the supply of the dairies and farms.

These facts cannot fail to be of importance for legislation, if hereafter it should unfortunately be the case that the rinderpest should extend thus far westward, and in a direction from which foreign cattle are shipped for England.

Mecklenburg-Schwerin and Mecklenburg-Strelitz.

It was from these Duchies that some of the earliest accounts reached England respecting "the murrain,"

the appearance of which promptly led the Senate of Lubeck to interdict the passage of cattle into its territory, unless accompanied with a certificate of their being in a perfect state of health, and created also much anxiety as to whether the malady might not soon extend to our own country. The alarm, however, seems to have arisen out of the circumstance that pleuro-pneumonia, which had occasionally of late years affected the cattle in Mecklenburg, in common with other continental states, showed itself somewhat suddenly in March, 1856, at the village of Great Görnon, near to Steinberg. Its outbreak is attributed to the introduction of some cattle from Bavaria; and it appears that the "court cattle which were in the same stable" were subsequently attacked. After the death of several, the remainder of the animals were killed, and buried entire.

This summary proceeding appears to have arrested the disease in that particular village; but cases are said to have occurred in other parts of the Duchies. The interdict which was laid on the estate of Great Görnon concerning the "export, import, and transit of cattle, immediately on the outbreak of the disease," was not, however, removed until Oct. 1st of the same year, after which time free intercourse was allowed.

On this fact being officially communicated to the authorities at Lübeck, and also that the whole of Mecklenburg was free from the disease, the Senate removed the restrictions which had been placed in the way of cattle entering their territory; but, as has been observed in that part of this report which specially refers to Lübeck, these were again enforced in February of the present year, in consequence of the re-appearance of the disease in the Duchies of Mecklenburg.

On the 24th of December, 1856, the Commissioners of our Customs published an order with regard to a more rigid examination by the Inspectors of Foreign Cattle, "with special reference to a contagious disease called 'murrain,' which has recently broken out amongst the horned cattle of Mecklenburg." Count Bulow, Minister to the Grand Duke of Mecklenburg-Schwerin, complained of this order to Lord Blomfield, her Majesty's Ambassador to the Court of Prussia, and requested that the attention of the Home Government might be directed to it; and Lord Blomfield thereupon sent a despatch to the Earl of Clarendon, to the following effect:

"Berlin, January 23, 1857.

"My Lord,—I have the honour to inclose to your lordship herewith a copy of a communication which I have received from Count Bulow, Minister of his Royal Highness the Grand Duke of Mecklenburg-Schwerin, requesting me to draw the attention of her Majesty's Government to the injurious effects which the publication of the Custom House order, published in London the 24th December, 1856, respecting the importation of cattle, alleged to be diseased, from the Mecklenburg States, is likely to have on the commerce of the country. Count Bulow states that 'the cattle murrain," alluded to in this order as now existing in Mecklenburg, has only manifested itself twice, for a short period, during the years 1855, 1856; and that in each case measures of such a stringent nature were taken as effectually arrested the spreading of the disease, insomuch that since the 1st of October last all the measures of precaution that were in force for its prevention have been suspended by the official order to this effect, a copy of which Count Bulow has transmitted to me, and which, in original and translation, I have the honour to forward herewith to your lordship. "I have, &c.,

(Signed) "Blomfield."

From this and all the additional information which we have collected, it would appear that there was very little cause for danger to be apprehended, and none in so far as our country was concerned, from the state of the health of the cattle of Mecklenburg, the so-called "murrain" being only the affection known as pleuro-pneumonia.

Saxony.

This kingdom is perfectly free from rinderpest, and has been so for many years. Scarcely any apprehensions are entertained that the disease would reach the country, even if it were to encroach very much more upon the Prussian frontiers of Russia and Poland, or prevail to a far greater extent than it has recently done in Silesia, as the severity with which the preventive laws of those countries is carried out is viewed as affording all the security which is required.

Eczema epizootica has been somewhat rife of late, and many cases are still to be met with. Pleuro-pneumonia has only existed in a sporadic form in Saxony and Central Germany, and has, therefore, not excited so much of the public attention here as elsewhere. The laws in force with reference to cattle diseases are almost identical with those which have already been made mention of in this report.

The investigations in Saxony completed our inspection of the chief course of the river Elbe, and showed that all the countries through which it flows were entirely free from the rinderpest, a result equally as satisfactory as that which had previously been ascertained with reference to the Weser.

Prussia.

Finding that the rinderpest had no existence in the countries we had already passed through, we proceeded to Berlin with a view of going to Konigsburg, and thence into Courland, as, according to the information we were at present in possession of, it was here that the malady was prevailing to some considerable extent.

Arriving at Berlin, we first called on the professors of the Veterinary School, who, by virtue of their appointments under Government, are always put in possession of the latest information with regard to the existence and extent of contagious diseases among domesticated animals. From them we learned that the entire district we had proposed to visit was now perfectly free from the pest, and that, if it existed anywhere in Prussia, it would probably be found in the neighbourhood of Breslau, in the province of Silesia. They further also informed us that there was but little chance of our being able to study the nature and symptons of the pest in any part of the Prussian dominions, from the summary proceedings which are invariably had recourse to, for its immediate extirpation, and that for the purpose of seeing the malady in its different stages, we should have to go into Austro-Poland, or some other part of the Austrian empire, where the laws are somewhat less stringent, and not so rigorously enforced as in Prussia. We ascertained also that in all probability, in the event of our succeeding in obtaining an entrance within the Prussian military cordon, we should not be allowed to repass it in a less period than three weeks, and even then we should most likely have to leave the clothes we had worn behind us, besides having ourselves to undergo a disinfecting process.

Under these circumstances we sought an interview with Lord Augustus Loftus, her Majesty's *Chargé d'Affaires*, in the absence of Lord Blomfield, minister at Berlin, with a view of obtaining from the Government of Prussia the latest particulars with regard to the location of the malady, and that amount of assistance and protection which we needed for the fulfilment of our mission.

This interview was at once granted, and we were most courteously received by his lordship, who manifested the liveliest interest in the question, and also expressed his willingness to do all he could in furtherance of our object. His lordship explained at some length his views as to the absolute necessity of keeping up of a

strict *surveillance* over all articles of commerce which were likely to carry the *materies morbi* of the cattle pest, and of the danger which would be incurred in the event of its extension, by allowing the importations to go on from the great ports of the Weser and the Elbe; facts which have already been alluded to in the former part of this report. Lord Loftus also dwelt on the amount of danger which might probably arise from the free importation of bones from Russia and the Baltic ports, and instanced a case where an outbreak of the malady was believed to have depended on the conveyance of the bones of an animal dying with the affection into a stable in which other cattle were placed.

His lordship requested that I would write to him, stating the object of our inquiry and the requirements we needed from the Government. He also promised that he would put himself in immediate communication with Baron Manteuffel, and would likewise write to his Excellency Sir Hamilton Seymour, her Majesty's ambassador at the Court of Vienna, to procure for us letters of introduction and recommendation to the authorities in the Cracow division of Galicia, in the event of its being found necessary to go thus far to complete our inquiry.

A letter containing his lordship's suggestions was thereupon forwarded to him, and to this I had the honour of receiving the following reply with the subjoined enclosure:—

"Berlin, April 23, 1857.

"SIR,—I beg to acknowledge the receipt of your letter of this date.

"I enclose to you herewith copy of a letter I have addressed to Baron Manteuffel, requesting H. E. to give you a letter of recommendation for the proper authorities at Breslau; and I shall not fail to forward to you without delay H. E.'s reply.

"I shall likewise request Sir H. Seymour to procure for you a similar introduction to the authorities at Cracow, and shall further beg him to forward the reply to your address, 'Poste restante à Cracovie.' "I have, &c.,

"AUGUSTUS LOFTUS.

'Professor Simonds, Hotel Victoria, Berlin."

(*Enclosure.*)

"Berlin, ce 23 Avril, 1857.

"MONSIEUR LE BARON,—Le Professor Simonds, Membre du Collége Royal Vétérinaire à Londres, vient d'arriver à Berlin, étant chargé d'étudier sur les lieux la nature et le traitement de l'épizootie qui s'est manifestés en plusieurs endroits sur la frontière de la Prusse et de l'Autriche. Se rendant Samedi prochain dans ce bût à Breslau, et désirant acquérir la protection et l'assistance des autorités Prussiennes, il s'est addressé à moi, me priant de solliciter de V. E. une lettre de recommandation pour S. E. Monsieur le Président Supérieur de la Province de Silésie.

"J'ai donc eu recours à l'obligéance si souvent éprouvée de V. E., en la priant de vouloir bien recommander le Professeur Simonds soit à la haute protection du Président Supérieur ou à la bienveillance des autorités compétentes de cette province.

"Je dois avertir V. E. que le Professeur compte quitter Berlin pour cette province Samedi prochain.

"Je profite de cette occasion, &c.,

"(Signé) AUGUSTUS LOFTUS.

"A. S. E. la Baron de Manteuffel."

His Excellency Baron Manteuffel most readily complied with the request thus made, and in the eveningof the same day Lord Loftus wrote as follows:—

"Berlin, April 23, 1857.

"SIR,—Baron Manteuffel has told me that he will forward, or cause to be forwarded, though M. de Raumer, a letter of recommendation for you to the Upper President of the province of Silesia, so that on your arrival at Breslau you may at once announce yourselves to Baron Schleinitz.

"I enclose herewith the despatch for Mr. Ward, her Majesty's Consul-General at Leipzic, to whom I likewise enclose for you a letter of introduction. I am, Sir, &c.

"AUGUSTUS LOFTUS.

"Professor Simonds, Hotel Victoria."

Being now furnished with all the necessary letters of recommendation, we made our way as quickly as possible into Silesia; and arriving at Breslau, at once reported ourselves to Baron Schleinitz, by whom we were also most courteously received, and who had already prepared for our use a written account of the progress which the disease had made in the spring of the present year in his province.

The Baron met us by somewhat facetiously remarking, "that fortunately for Prussia, but perhaps very unfortunately for us, who had travelled so far to study the nature of rinderpest, it had no existence just now in Silesia." He traced, however, upon the map the different places where it had recently prevailed near to the Polish frontier, and which he himself had visited. He likewise related several remarkable instances of the highly infectious nature of the disease, and of its conveyance from place to place by *indirect* means of contagion. The following is a translation of the report alluded to:—

"*Report of the Disease which prevailed among the Horned Cattle in the Province of Silesia during the months of March and April*, 1857.

"The rinderpest, which in the present year has visited the province of Silesia, has, with one exception, in which the precise manner that the infection was carried to the premises could not be satisfactorily ascertained, been clearly traced to the introduction of two herds of cattle from Galicia, of the Podolian or Hungarian breed, numbering respectively 44 and 37. These beasts were purchased by different landowners, and were brought to their several estates in an apparently healthy condition. Some of the animals have remained in health, as, for example, those which were taken to L. Guttentag, in the circle of Lublinitz, and to Blazeiowitz, in the circle of Tost-Gleiwitz, but others of them became the subjects of the disease.

"THE GOVERNMENT DISTRICTS OF BRESLAU.

"Eight oxen were brought to the domain or estate of Furatenau, circle of Neumarkt, and were put into a stable with some other cattle. In a few days the eight oxen fell ill, and, on the disease being recognized as the rinderpest, they were immediately slaughtered. They had, however, already infected the others, and, on several becoming diseased, the whole herd, consisting of twenty-one animals, was likewise slaughtered. On the same estate there were *eighty* cows, but these were living in other sheds, and did not come in contact with the diseased animals; and, moreover in the same village there are upwards of *one hundred cattle-owners*, but the whole of the cattle were preserved by the summary measures had recourse to. The sanitary *cordon* drawn around the estate was removed twelve days since; three weeks having elapsed since the last case, and everything used about the animals being disinfected.

"THE GOVERNMENT DISTRICT OF OPPELN.

"1. Twenty oxen were brought to the estate of Schweieben, in the circle of Tost Gleiwitz, and on their arrival they were distributed to the different stations (farms) of the estate. The disease also broke out among these animals, and, as they sickened, they were removed to a station where only sheep were kept, and here slaughtered. A military cordon was also drawn around the place. Notwithstanding this precaution, the disease spread thus—

"*a. In Schweieben* one ox was attacked, and he, with another with which he was standing, was immediately killed. The further progress of the disease was at once arrested, although there were 120 head of other cattle on the estate, and in the village also about a hundred cattle-owners.

"*b. Station Radum.*—An ox which showed premonitory symptoms was immediately killed, together with another that he was standing next to, and no other cases have occurred.

"*c. Station Wischnitz.*—The appearance of the rinderpest at this station is very remarkable. It appears that either four or six of the Podolian oxen were sent here, and remained for a few days. These animals gave no evidence of being affected; but *twenty* days after their departure, one animal of a herd of

19, that they had been placed with, fell ill with the disease, and the whole were forthwith slaughtered.

"2. At Ponischowitz.—Twenty Podolian oxen came here on the same occasion, and they within a few days gave indications of being affected. Like the others, also, they had been put with other cattle, 49 in number. On the occurrence of the outbreak the whole were killed, so that not a single head of cattle was left on the estate. The place was likewise surrounded by a military cordon; but while the disease was going on, a carpenter's apprentice, employed on the estate, escaped the vigilence of the guards, and went to his father's house, which was distant about two thousand paces. While there he repaired a manger in his father's cow-shed, and also changed the clothes he had worn at Ponischowitz. The rinderpest in consequence of this broke out among his father's cattle. The whole were thereupon killed, and a military *cordon* drawn around the premises. It is now ten days since the animals were slaughtered.

"3. At Slupsho, four of the Podolian oxen sent here were attacked. They were likewise slaughtered, and the further progress of the disease arrested. The *cordon* has been raised here four weeks; the place having been previously disinfected.

"4. At Zawaiz, in the circle of Beuthen, at a totally isolated farm, a case of sudden death occurred to an ox, which the surgeon reported as happening from rinderpest; but there is considerable doubt as to this opinion being correct.

"5. At Wohlau, in the circle of Pless, close to the frontier of Galicia, and into which no cattle had been imported, three cases of the disease occurred, and all at peasants'. These animals had come in contact with nine others, and all were consequently killed and a military cordon established. In this particular instance it was impossible to trace the cause of the introduction of the disease.

"These are all the cases of rinderpest which have recently occurred in the provinces of Silesia, and at the present time not a single suspicious case exists, owing to the means which the Government has adopted to arrest its course. No fear need be entertained that the disease will extend from Prussia to the neighbouring countries.

"(Signed) BARON SCHLEINITZ.
"Privy Councillor to his Majesty the King of Prussia, and Upper President of the province of Silesia.
"Breslau, April 27th, 1857."

It will not be necessary to comment on this Report in this place, and more particularly as we shall have hereafter to adduce some remarkable proofs of the contagious nature of the rinderpest. It is right, however, as several parts of Prussia have experienced during the last two years different outbreaks of the malady, and as its extension in this kingdom especially is an object of much practical importance, as thereby a greater risk is incurred of its reaching those countries which are in direct communication with our ports, that as complete a history of these recent visitations should be here given as we have been able to collect.

The Recent Outbreak of the Rinderpest in Eastern Europe.

Throughout the late war, the movements of the Russian troops necessarily called for the transit of large numbers of cattle to those places which the army successively occupied; and it appears more than probable that the wide diffusion of the "steppe murrain" which has occurred within the last three years has depended entirely upon this cause.

The ordinary traffic in cattle leads, it is true, to the annual removal of large herds from the steppes; and hence the outbreaks of the rinderpest in those countries which are otherwise free from it can often be traced to the animals which find their way from the various fairs and markets. No cause, however, is so potent in the spread of the disease as the outbreak of a Russian war; and consequently, whenever circumstances have required the passage of her troops over the frontier, the pest has manifested itself in a far more extensive form.

Thus it is recorded that, "during the Russo-Turkish war in 1827 and 1828, the Russian cattle which were sent for the supply of the army carried the murrain with them, and that it destroyed no less than 30,000 head of cattle in Hungary, 12,000 in Galicia, and 9,000 in Moravia."

Again in 1831, 1832, and 1833, in consequence of the Polish insurrection, the disease committed great ravages in that country, causing considerable distress. At this period it also crossed the Prussian frontier, in the department of Bromberg, and, although quickly exterminated, swept away nearly 1,000 head of cattle.

In 1849-50 the malady again prevailed to a very great extent in Hungary, its introduction being due, according to the official report of M.M. Renault and Imlin, commissioners appointed by the French Government to inquire into the subject, to the passage of the Russian troops from Wallachia by way of Transylvania.

Very shortly also after the army of Russia was sent to occupy the Principalities, rumours of the cattle plague became current; and we find that as early as 1854 the disease had made considerable progress both in Volhynia and Podolia. From that period nearly down to the present the malady gradually extended itself, until it reached most of the countries in Eastern Europe, and some parts even of Asia Minor. From the Principalities it can be traced in a northerly and westerly direction into Moravia, Galicia, Poland, Prussia, Lithuania, &c.; easterly into Bessarabia, Southern Russia, and the Crimea; as also into Turkey, and to the southern shore of the Black Sea.

We have not been able to arrive at any correct estimate of the immense losses these several countries sustained in consequence of this visitation; but it has been officialy reported that no less than 26,442 head of cattle were destroyed in the Austrian dominions in the year 1856. And Consul-General Mansfield, in a despatch from Warsaw, states that from May 9th, 1856, to the date of his report, March 29th, 1857, twenty thousand beasts had been sacrificed in Poland alone. It has likewise been said that the French army lost in Samsoun 8,000 beasts out of 17,500 in the space of nine months, and that we lost during the same time 4,000 out of 10,000 from the pest—facts which may help to convey an idea of the hundreds of thousands which were swept away.

Mr. Radcliffe, M.R.C.S., who lately held a commission in the Ottoman army, reports that, while he was stationed at Sinope, the murrain was developed towards the termination of the spring or early part of the summer of 1855, and that in the month of June it reached its acme. "Scattered cases," he adds, "occurred, however, from time to time until November, when, about the second or third week of the month, the disease broke out again with great fierceness, spread rapidly among the cattle in the depôt and in the town, reached a second acme about the termination of the month, declined during December, and ceased altogether in January, 1856."

Among many others also, Mr. Walton Mayer, V.S. to the "Royal Engineer Field Equipment," who was, during the war, attached to the Land Transport Corps, speaks of the existence of the disease in several parts of Turkey, and in the immediate neighbourhood of Constantinople, in the summer of 1855. Early in the same year, in consequence of a considerable part of both Austrian and Russian Poland having become the seat of the disease, much apprehension was shown lest it should cross the Prussian frontier. To prevent this the Prussian Government took the precaution of sending detachments of troops to all the points of egress below Thorn, with a view of cutting off the communication with the infected localities.

M. V. Schleinitz, President of the department of Bromberg, in the province of Posen, in his official report, says, that "it was in the month of March, 1855, that we were obliged to order the frontier to be closed, which was first effected in pursuance of the directions in section 2 of the law of 1836. In October of the same year we were under the necessity, in consequence of the threatening approach of danger, of putting into force the severer directions of section 3 respecting the closing of the frontier; and when, at the end of that month, intelligence, though not officially confirmed, arrived here regarding the progress of the murrain, we caused the Polish district bordering upon our department to be thoroughly investigated by the veterinary surgeon of our department within a distance of three miles from the boundary of our territory."

"It being then ascertained that the disease was only $2\frac{1}{2}$ miles from our frontier, we determined, at the beginning of November, to close the same still more strictly, according to section 4 of the said law. At the same time we ordered the district commissaries of police to inform the mayors of the different places of the impending calamity, who were not only instructed to exhort the inhabitants of their districts to use the greatest precaution, but also to give immediate notice, per express, to the Councillor of administration of the district of every suspicious case of disease breaking out among the cattle."

"As a further warning and instruction to the public, we caused copies of the circular which was issued by the chief magistrate of our province, under the date of 28th January, 1845, to be printed and distributed, to which we annexed a description of the symptoms of the disease, and caused the same to be distributed as a supplement to our official paper (*Gazette*). Besides this we prohibited the attendance of persons at the weekly markets of the towns lying nearest to the threatened boundary with those species of cattle, as well as with other things likely to convey infection, and which the law of 1833 specially enumerates; we likewise ordered establishments to be erected for personal purification in the villages wherein the frontier custom-office is established; stationed gendarmes in the villages on our side of the boundary situated nearest the infected Polish districts, and charged the district commissaries in the immediate neighbourhood, under pain of dismissal from office, with the execution of the preventive measures in case the contagion should break out in our territory. We further empowered the Councillors of the Administration of the district to order the district veterinary surgeons to inspect the villages and places on the boundary as often as necessity required, and to watch over the state of the health of the cattle there."

Notwithstanding these precautions were rigorously adopted, the disease crossed the Prussian frontier; and in the latter part of November, 1855, it manifested itself in the circle of Inowraclaw, and shortly afterwards in the circle of Gnesen, near the town of Posen. The official report states, that on this occurrence "general measures were taken for closing the boundaries of the places infected, and special ones for the infected farmyards, by means of sentries posted under the superintendence of gendarmes; quarantine stables were established, superintendents and cattle inspectors appointed, and these persons provided with written instructions and bound by oath to their observance; all trade in cattle was forbidden within a circuit of three miles, all dogs chained up, and every proprietor of cattle within a circuit of two miles from the infected place was bound upon pain of incurring the penalty of sec. 309 of the Criminal Law, to give immediate notice even of the least symptom of disease among his cattle, to the mayor of the place, who had forthwith to inform the Councillor of the Administration of the district by an express messenger, of such cases of disease, provided they did not proceed from exterior injuries."

"These measures for prevention and cutting off intercourse were in no instance abandoned before the expiration of the fourth week; and the carcases of the cattle that had died of the pest, or had been killed in consequence of its appearance in infected districts, no matter whether diseased or healthy, were always, after their skins had been cut into pieces on all parts of the body, buried in pits from six to eight feet deep, each carcase being previously covered with unslackened lime."

At the first the chief execution of these preventive means on the several farms was intrusted to civilians, but very early in the progress of the malady the military was employed. The disease presently began to subside, but despite every precaution occasional cases occurred, so that the department of Bromberg was not entirely freed from it until the beginning of 1856.

The *cordon*, however, on the frontier of Poland was not raised; but on a decline of the disease in that country a removal of the impediments which had been placed in the way of trade was gladly permitted. Individuals who could satisfy the officers of the urgency of their business—which, however, must not be in connection with cattle or cattle offal—were, by reason of a certificate from the Councillor of Administration of the district, allowed to cross the frontier, through the custom offices, into Poland. Upon similar conditions foot passengers, who must, however, be furnished with only the most necessary requirements, were likewise permitted to pass into the department of Bromberg from Poland. Nevertheless all individuals crossing the frontier, together with their effects, were required to be disinfected in the establishments erected for that purpose at the boundary custom place, under the superintendence of a gendarme.

Persons travelling post were likewise subject to the same regulations, and spun goods were not allowed to enter.

Early in 1856—namely, in the month of April—the disease also broke out in the department of Breslau, in the province of Silesia. For the particulars of this occurrence we are indebted to Lord Loftus, to whom they were officially communicated by the Prussian Government. The report states that "for forty years the department had been entirely free from the rinderpest, but that the disease had existed therein during the 'War of Independence.'" "All investigations have failed," it says, "to show the precise manner in which the outbreak occurred; but it appears that the disease came from the circle of Schrimm, in the district of Posen. The means of its extension from the circle of Schrimm are the more obscure, because those persons who might have been the cause of the conveyance of the infection are interested in not giving correct information. A knowledge of the existence of the pest only reached the authorities at Breslau after three different circles were more or less affected, which circumstance arose from the want of experience of the district veterinary surgeons, none having had an opportunity of previously seeing the disease. Subsequently, also, about a month elapsed before correct reports were obtained from the commissioners who were specially appointed for the investigation, arising from the great distances they had to travel, and the difficulties which were in the way of their making *post-mortem* examinations."

"The disease lasted for seven months; and its continuance so long depended in part on the footing it obtained while the investigations were going on, as during this time many animals were inadvertently exposed to the infection; and consequently they had the malady incubated in their systems when the preventive

measures were enforced. Another cause of this long duration of the malady is to be found in the difficulties which were experienced in the adoption of the sanitary laws, and the want of zeal on the part of the public in giving effect to them."

In October, the disease declined in the different circles, and was nearly extirpated; but, about the middle of November, it reappeared in the villages of Braunau and Seitsch, which doubtless depended on a second communication being established between them and some of the still infected farms. The following table shows the number of the places affected, together with the quantity of cattle kept, and the result of the outbreak:

Circle.	Number of Infected Villages.	Number of Infected Farms.	Number of Cattle kept in the Villages.	Died.	Killed.		Total Loss.
					Diseased	Healthy.	
Wohlau .	5	7	828	5	8	10	23
Steinau..	4	35	487	97	78	107	282
Guhrau..	15	77	4213	151	423	187	761
	24	119	5528	253	509	304	1066

The report states, in conclusion, that, "considering the extent of the circles, and the number of cattle kept in them, together with the length of time which elapsed before a correct diagnosis was arrived at, the loss is but a trifling one, and especially when it is compared with the thousands of animals which are sacrificed to the disease in other countries."

Subsequently to the extirpation of the pest from this part of Silesia, in November, 1856, the province continued free until the month of March of the present year, when, as has been previously explained by the official report which we have previously inserted on the authority of Baron Schleinitz, some villages lying near to the frontier of Galicia were affected by "the introduction of two herds of cattle from that country." It thus appears that Silesia has experienced two separate outbreaks, the first during the year 1856, and the second in 1857.

By the extension of the disease northward Lithuania and Courland became affected, the pest showing itself in the latter-named province in the autumn of 1856, and continuing until January, 1857, with an estimated loss of 2000 head of cattle. Throughout the entire year of 1856, in consequence of the steady progress of the disease in Russian Poland, the importation of cattle, skins, bones, hair, &c., was strictly prohibited all along the Russian frontier of Eastern Prussia.

On the occurrence of cases at Kowno and Tauroggen, and particularly at Lansayen and Georgenburg, places near to the frontier in the circle of Tilset, more severe measures were adopted; the driving of cattle along the right bank of the Niemen was interdicted, and all traffic between the countries was suspended. No persons having to do with cattle were allowed to cross; or if so, they had to undergo a quarantine, while mail passengers were fumigated at the borders. In the month of August the authorities in the circle of Gumbinen were ordered to stop all the cattle and horse fairs which were to be held in the succeeding months of September and October.

By the strictest enforcement of these sanatary regulations this division of Prussia was preserved until the spring of 1857, when the malady crossed the frontier, and showed itself in the villages of Bassnitzkehmen and Meldiglaucken on the 2nd and 3rd of April. The disease, however, was at once arrested by the establishment of a military cordon, and by the wholesale slaughter of the animals affected, as also of those suspected to be diseased, and the burial of their carcasses in quicklime in holes 8 feet deep.

It was this immediate arrestation of the pest in this district which induced us, as has been previously observed, to alter our route and to go on to Silesia, instead of Eastern Prussia and Courland, with a view of studying the nature of the malady.

From the preceding particulars it appears, then, that since the latter part of 1855 the disease has entered the kingdom of Prussia from adjacent countries in three of its different provinces, namely, in November 1855, in the circle of Inowraclaw, province of Posen; in March, 1857, in the districts of Tost-Gleiwitz and Lubinitz, province of Silesia; and in the following April in the villages of Bassnitzkehmen and Meldiglaucken, province of East Prussia; besides having prevailed for several months in 1856 in other parts of Silesia, coming there from Posen.

Galicia.

Leaving Silesia, we proceeded to Cracow, taking with us letters of recommendation from Baron Schleinitz to Count Clam Martinitz, President of this division of Galicia. Waiting our arrival also, we found at the *poste-restante* a similar communication from G. H. Seymour, her Majesty's Ambassador at Vienna, which was accompanied by the subjoined letter:—

"Vienna, April 27, 1856.

"Sir,—In compliance with the request made in your behalf by her Majesty's Legation at Berlin, I at once applied to the Minister of the Interior for the facilities of which you stand in need, and have now the pleasure of forwarding to you the enclosed letter of introduction for Count Clam Martinitz, President of the Government of Cracow, who has already received instructions by telegraph to afford you every possible assistance in the prosecution of the inquiries with which you have been entrusted by the Agricultural Societies of England, Scotland, and Ireland, under the sanction of her Majesty's Government.

"I am, &c.,

"J. B. Simonds, Esq." "G. H. Seymour.

On calling at the official residence of Count Clam Martinitz, we were immediately admitted to an audience, when, on presenting our letters of recommendation, his Excellency expressed his entire concurrence in the object of our mission, and his readiness to afford us every facility in his power in its accomplishment. He explained that, in his division of Galicia, the malady was fast declining, but in the circle of Neu Sandec, and also of Jaslo, a few cases would probably be met with. He likewise expressed an opinion that we might have to go as far as Lemberg to satisfactorily study the disease, as in that division of the country it prevailed to a much greater extent. In the event of this being found necessary, he kindly promised to furnish us with all necessary letters of introduction to the Governor of the Lemberg division of Galicia, as well as to the local authorities of the places we should visit in his own governmental division, and also copies of the official documents relating to the progress of the disease, and the instructions issued by the commissioners of the sanitary laws.

In accordance with this arrangement, in the evening of the same day we had the honour to receive the following letter, with its several enclosures, two of which we here insert, namely, the statistical return of the progress of the disease, and the notice which regulates the proceedings of the sanitary commission.

"30th April, 1857.

"Sir,—I have the honour, according to my promise, to send you a letter for the Kreishauptman of Jaslo, and another for Count Gotachowski at Lemberg. I think it proper to join one more addressed to the Kreishauptman of Tarnow (the place where you are to leave the railroad), in case you should need any assistance relating to your further journey. I send you also the papers we have spoken of. "I am, &c.,

"J. B. Simonds, Esq." "Clam Martinitz.

(Enclosure No. 1.)

GENERAL REPORT of the PROGRESS of the RINDERPEST in the GOVERNMENT of CRACOW, from the 1st to the 15th of April, 1857.—Cracow, 23rd April, 1857.

Circle.	Names of Villages.	Date of the Outbreak.	No. of Cattle.	No. of infected Farms.	Sick on 1st April, 1857.	Increase to Apr. 15.	Total No. of Sick.	Recovered.	Died.	Killed.	Remained April 15.	Total from the time of the outbreak of the Disease.

(Translation.) (Enclosure No. 2.)

"*Circular Notice of the Imperial Royal Government of Galicia respecting the Slaughtering of Cattle to prevent the spreading of the Rinderpest.*

"To prevent the spreading of this disease by the means which are at the command of the Minister of the Interior, it has been deemed expedient to issue the following orders:—

"1st. That whenever there are reasons to suspect the existence of the pest, all diseases occurring among cattle shall be carefully watched; and when the least doubt exists as to the nature of the affection, the animal shall be killed, and a *post mortem* examination made with a view of ascertaining as far as possible the exact nature of its ailment.

"(*a*) The disease having been declared suspicious by a medical officer duly appointed for that purpose; and

"(*b*) The local authorities having been informed by the medical officer of his opinion, they shall jointly proceed to value the animal to be slaughtered, according to the manner hereafter described.

"2nd. Slaughtering is to be enforced in the Austrian dominions when the rinderpest already prevails—

"(*a*) At its outbreak in places which have hitherto been free from it.

"(*b*) When the disease is well marked in its characters, symptoms, and duration, or by its violence and destructiveness, and when also the police measures which have been already taken have been without effect in checking its progress, so that there is a probability that either the malady by the slaughtering may be suddenly brought to an end, or that its further spreading may be entirely or partly prevented, to enable the communication between healthy and diseased districts to be speedily re-established.

"(*c*) The ultimate decision as to whether the slaughtering shall be enforced when the certainty of the presence of the rinderpest has been decided on, and to what extent it shall be carried, is to depend on the commissioners who are appointed for that purpose, who, after having been duly informed of the outbreak of the rinderpest or other disease of a suspicious nature, or the spreading of the same in the infected communes, shall, conjointly with those who are charged with the carrying out of the veterinary police regulations, and also, if possible, with a medical officer acquainted with the disease, and two sworn valuers, taken from the commune, who are well acquainted with the price of farm stock, first value the cattle which it has been decided to slaughter. A special report is to be made of the proceedings to the competent authorities.

"3rd. With reference to the question by whom and in what manner the estimated value is to be paid to the owner of the condemned cattle, and whether it is ultimately to be paid by an order on the Treasury from the police authority of the district—

"(*a*) The owner will receive the full value ordered by the authorities, after deduction has been made for the parts that may be used, as determined by competent authorities, for the cattle which have been killed on suspicion under rule 1, with a view to ascertain if the disease was the rinderpest or not.

"(*b*) For those cattle where no doubt exists as to the nature of the disease being the rinderpest, and in those districts in the Austrian dominions which are known to be infected. And when the slaughtering shall have been ordered by the authorities, the owner shall only be entitled to receive the amount of their value on condition that he has not neglected any of the precautions which are prescribed by the veterinary police, and thereby contributed to the spread of the infection among his stock, or has in no way concealed the disease after the outbreak on his premises.

"(*c*) Under the same circumstances of the existence of the disease, the sum named by the valuers, after deducting the worth of the parts allowed to be used, such as the skin and horns, when properly disinfected, will be paid for every head of cattle killed by order of the commissioners.

"(*d*) With a view to facilitate those proprietors whose cattle have been slaughtered by the commission for the purpose of ascertaining the nature of the disease, and when it has been proved not to be the rinderpest, in replacing their cattle speedily, the district authorities are empowered to order the payment to be made out of the district funds, and to duly inform the superior authorities of the same.

"4th. To estimate the true value of the cattle ordered to be slaughtered by the commission, the local authorities as well as the sworn valuers will have to take into consideration the market value, age, and breed of every animal submitted to them.

"5th. With regard to the cattle which have been killed as suspected, but which are found on a *sectio cadaveris* to be perfectly free from the disease, the flesh of the same may be used for food, and the hide, horns, and tallow as articles of commerce. Of those, also, which were known to be affected by the pest, or were discovered to be diseased on the making of the *post mortem* examination, the horns, fat, and hides may be used for commercial purposes, but only on the regulations framed for that end being strictly complied with; and it is ordained that in these instances the parts shall be valued, and deduction made from the amount to be paid to the proprietors.

"The attention of the local authorities and veterinary police is specially directed to this point.

"Lastly. It is ordered that these fresh directions of the district government upon the necessity of the slaughtering of cattle to prevent the spreading of the rinderpest be in force from the present time.

"Lemberg, 17th September, 1850."

Immediately on the receipt of these official documents and our letters of introduction from Count Clam Martinitz, we set forward on our journey to Neu Sandec *via* Bochnia, passing over the great rock-salt formation of Austro-Poland in company with Professor Nicklas, of the Veterinary School at Munich, whom we had previously met at Berlin, and who had been sent by the authorities of Bavaria on a similar mission to ourselves.

Arriving at Neu Sandec, our first business was to wait upon the President of the department, who referred us to the district physician for the latest particulars as to the precise location of the disease, as the week's report had not yet reached his office.

It may be aswell here to observe that in this part of the Austrian dominions there are no scientifically educated veterinary surgeons; and that from the frequent occurrence of epizootic diseases, both physicians and surgeons are appointed by the Government as inspectors of the health of cattle, and to act also as commissioners of veterinary sanitary police during the prevalence of these affections. To fit them for this purpose, they have to make this class of maladies their special study, and subsequently to undergo an examination as a test of their competency.

By the district physician we were placed in communication with M. Carl Zankel, surgeon and commissioner of Alt Sandec, who received instructions to accompany us forthwith to the different places where the disease existed; and to proceed, in the first instance, to a village called Ludowica, lying at the foot of the high range of the Carpathian mountains, where a case had just occurred, and which it was hoped that we might succeed in seeing before the animal was destroyed.

On reaching Ludowica we were at once admitted within the *cordon*, when we found that this animal, together with nine others which had been exposed to the infection with him, had already been slaughtered and buried. An application was made to have the bodies disinterred, but which for want of due formality was not complied with—Ludowica, in fact, being outside the circle of Alt Sandec, to which M. Zankel was attached, and we not having with us a *special* order from the President to the authorities of the circle we were now in for the disinterment.

The slaughtering had swept away all the animals in the village which were known to have been exposed to the infectious influence of the disease, and consequently we pressed forward through the mountain passes, which here chiefly consisted of the partially-dried beds of rivers and streams, to another village called Zabrzez. It was somewhat singular that at Zabrzez we came upon the identical farm where the malady had first showed itself in this locality, and saw on the premises four of the original Steppe oxen by which it had been brought. Three of these had been the subjects of the disease, but had recovered, and the fourth had resisted the contagion throughout, as was believed, because he had before been affected. They were tied up to fatten, and had every appearance of perfect health, having no trace of disease of any kind about them.

Besides these, there were nine other animals on the farm in quarantine, consisting of three oxen, a young bull, and five cows. They also were feeding, and looking well. Twelve days had elapsed since the occurrence of the last death; and we learned that should no other case happen, the animals would not be liberated till the completion of the twenty-first day from the time of the last death.

Leaving Zabrzez, we went on to Kamienica, five miles distant, and the head-quarters of the Austrian commission, which had been specially sent to administer the sanitary laws applicable to the rinderpest. The

commission was constituted of Dr. Anton Karger and M. Johann Rucki, "Imperial Royal Commissioners of sanitary police for Epizooties," and from them, during our entire stay, we not only experienced all the assistance in their power in furtherance of our inquiry, but likewise the greatest kindness and friendship. We were thus left free to pass as often as occasion required between Kamienica and Zabrzez, and so to act in our investigations, both within and without the *cordon*, as scarcely could be anticipated, when the austerity of military discipline in these cases is considered, and which compensated in a great measure for our oat-straw beds and sour rye-bread repasts.

In Kamienica we found two quarantine stations, in one of which seven animals were placed, and in the other nine. Two days prior to our arrival a case had occurred in the first station, and more were daily looked for. The animal in question, a cow, was observed by her owner, late in the evening of Thursday, April 30th, to be out of health. She was reported early on the following morning, and immediately seen by the Commissioners, who at once recognised the pest. She lived till 2 p.m. on Saturday, May 2nd, only surviving the attack about forty-two hours. After the body had been examined—and which has to be done in every instance—it was buried. The skin, however, was allowed to be removed for the owner's use subsequent to its being disinfected and prepared under the inspection of the proper officers.

At our first visit to these quarantine stations, in company with the Commissioners and Professor Nicklas, and which was late in the afterpart of Monday, May 4th, no indications of disease could be detected in any of the animals—a fact not without some value, as, on our second visit, at 6 a.m. of the following day, an aged cow, one of the seven, exhibited some of the premonitory symptoms of the pest. This case will hereafter be referred to.

According to arrangement, we next proceeded to exhume the animal which had died on Saturday, that we might note for ourselves the several lesions which had been produced by the disease. We found that all the viscera of the chest had been removed, and were lying by the side of the body, and on bringing both these and the carcase to the surface, we were forcibly struck by the circumstance that so little decomposition had taken place, that no unpleasant smell attended our operations, although the animal had been dead about 65 hours. The flesh also was firm, and of a normal colour; the blood, however, was still fluid in the vessels, and of a darker hue than natural. It will not be necessary to give a detailed account of the morbid appearances which were met with in the viscera, and more especially as, in the course of this report, we shall have to describe these *in extenso* as they were observed in other cases; suffice therefore to say, that although they left no doubt of the animal having died from the rinderpest, they opened up new ideas in our minds as to the pathology of the disease.

Before proceeding to a description of the nature and symptoms of the malady, or the relation of individual cases of it, we propose to give in the next place the

History of the Appearance of the Rinderpest in Zabrzez and Kamienica.

Until the present occasion, the villages of Zabrzez and Kamienica, as well as all the surrounding district, have been perfectly free from the disease since 1846. The present outbreak took place in the month of March, and was due to the introduction of 10 steppe oxen which had been purchased at a cattle fair held at Jacmirz, in the Lemberg division of Galicia. These oxen came with large droves from Bessarabia, and from three to four thousand head were brought together at the fair. Jacmirz is about twenty German miles from Zabrzez, and three full days were occupied in driving the animals to the latter-named place.

They were bought by M. Berl Krumholz, farmer and distiller, and arrived at the farm on the 15th of the same month, and, after remaining a few hours, were sent on to Kamienica, where the distillery is situated. They were here put with 14 fat oxen, but, in consequence of these being sold for slaughtering two days afterwards, the steppe cattle were returned to Zabrzez on the 18th. Here they were placed in a stable by themselves, and stood there until the 20th, when four of them were a second time sent to Kamienica, with 10 head of young stock, and on their arrival were placed with 21 others. On the following day, the 21st, the six steppe oxen left at Zabrzez were observed to be trembling, which being supposed to depend on exposure to cold, they were put into a shed for warmth, in which were 18 other animals, consisting of some young bulls, cows, and two calves. On the 22nd, the four steppe oxen at Kamienica were likewise noticed to be unwell and trembling, and, the true nature of their illness being now suspected, they were immediately removed from the other stock, and orders were sent to Zabrzez for the six to be also taken away and kept by themselves.

As a further security to the stock at Kamienica, early the next morning the four steppe cattle were sent back to the farm at Zabrzez. Notwithstanding this precaution, the disease broke out among the young stock on the 30th, and eight of them died on the first day; and by April 3rd, thirty-one in all were dead. Besides these animals, M. Berl Krumholz had ten others at Kamienica, and the Commissioners decided upon killing them at once, so that he might receive something towards his loss. The entire number, therefore, lost by him Kamienica was 41 animals; and had it not been for the selling of the 14 fat oxen, they also in all probability would have been sacrificed.

On the same day that the disease manifested itself at Kamienica it also broke out at Zabrzez among the eighteen with which the steppe oxen were placed on the 21st. Of the entire 28 animals located here, including the 10 steppe cattle, thirteen died, eleven were killed, three recovered, and one resisted the infection entirely. The three animals which recovered, and the one which escaped the attack, were all steppe oxen: they have been previously mentioned as being seen by us on our first visit to the farm.

The establishment of the *cordon* confined the disease entirely to this farm, although there were in the village altogether 453 head of cattle, the greater part of which were very poor and weak animals, badly fed and badly provided for.

The progress of the disease was rather singular at Zabrzez—thus, 11 of the 13 deaths had occurred by the end of the third day of the outbreak; every one of the animals dying which up to that time had shown symptoms of the disease. On the ninth day subsequent to the death of these, another animal sickened and died, and on the fourteenth day after its attack a second; while in twelve days more a third was taken ill, namely, a young bull, whose case will be hereafter recorded in full as coming under our own immediate investigation.

Notwithstanding that the same sanitary measures were taken at Kamienica as at Zabrzez, the disease reached the village cattle, but was fortunately prevented making much havoc among them. The ultimate result of the outbreak was that, out of 433 cattle kept in the village, 65 were attacked, of which 37 died, and 28 were slaughtered.

In Kamienica the malady chiefly prevailed among the cattle of the small proprietors and peasants; and the

daily lamentations of the poor women, to whom was confided the principal care, or rather, on whom was forced the labour of nursing and feeding the animals, at the losses they were sustaining, were most distressing to witness. Nearly the entire means of living of these small farmers depend on the well-being of their cattle; and to see them swept away by such a fatal scourge, could not fail to excite our deepest sympathy. A gloom was cast over the whole village; and fear seemed to be depicted on every countenance, lest the disease should still further extend itself.

As a warning to surrounding places, notice-boards were erected at the different entrances into the villages, setting forth, by their Polish and German inscriptions of "ZARAZA NA BYDLO ROGATE," and "HORN, VIEH SEUCHE," that the pest was there, while each fresh place of outbreak was instantly surrounded by the military *cordon*, and all communication effectually cut off.

Besides Zabrzez and Kamienica, two other adjacent villages in the circle of Kroscienko were the seat of the pest—namely, Tilka and Szchawnica. The total number of cattle kept in the former was 78, out of which 11 were attacked; and of these, 10 died, and 1 was slaughtered. In the latter place, 490 were kept, and 34 became the subjects of the malady; and of these, 25 died, 4 were slaughtered, and 5 recovered. It has been ascertained that the outbreak also in these instances depended upon the introduction of steppe oxen, bought at the same fair.

CHARACTERS OF THE DISEASE.

Infection.—Rinderpest properly belongs to that class of diseases which is denominated special or specific, by which we understand that there is either some certain and particular cause which gives origin to them, or that a marked peculiarity attends their progress and results. Affections of this kind most frequently possess the power of extension, by an inherent property of disseminating the *materies morbi* upon which they themselves depend, and which we recognize by the terms infection and contagion. Thus each victim may be viewed as adding new seeds to the malady, by the exhalations arising from its own body; it being a remarkable circumstance that, when the morbific matter has entered the system, it multiplies to an inconceivable extent before it is cast out by the organic functions. The circumstance of animals, when in health, contracting a disease of the same description as that affecting others with which they are located, is the best proof of the infectious or contagious nature of the malady. The escape of some under the same circumstances may be due to a variety of causes, and offers no satisfactory proof that the disease is *non*-contagious. For example, all animals are not equally susceptible of being acted on at the same time by the morbific matter: some may, therefore, resist its influence to-day, but in the course of a few days afterwards be susceptible of its action.

The facts which have been given with reference to the various outbreaks of the rinderpest do not require the addition of scientific deductions to establish more firmly the infectious nature of the malady. We believe that it stands second to none in its capability of spreading from animal to animal, *the cattle tribe being alone its victims*. If the malady were one that owed its extension to unexplained causes; if it suddenly showed itself in one part of the continent, and rapidly spread, despite all precautionary measures and without the introduction of diseased animals, to others near to or at a greater distance from its origin; if, in short, it possessed all the characters of an epizootic, then we might have some reason to doubt its infectious nature.

It has been stated, on indisputable authority, that any animal which has been exposed to the infection can propagate the disease without itself becoming affected; and that even cattle can do this before they are diseased, in consequence af the *materies morbi* being lodged in the hair which covers their bodies. This is by no means improbable, and the opinion receives support from the circumstance that in numberless instances persons visiting the sick cattle have conveyed the pest to other animals of the ox tribe. Thus we see that in these particulars the disease agrees with the small pox of sheep, or with the plague, small-pox, &c., of man, and that it is as infectious among cattle as the latter-named diseases are among ourselves.

There have been doubters of the infectious nature of the rinderpest; and whenever speculation has been allowed to take the place of facts, although it may seemingly have had science as its basis, great injury has resulted to those most interested in the question. A notable instance of this kind has been furnished us by Professor Renault, Director of the Alfort Veterinary School, and through his kindness we are enabled to transcribe the following particulars.

Towards the end of 1844 the rinderpest, which had prevailed among the cattle in Galicia, passed through Moravia, and made its appearance in Bohemia, in the circle of Koniggratz. The malady had already made some progress in the district, when M. Verner, chief of the Veterinary Department of Bohemia, was sent from Prague by the government to inquire into the precise nature of the affection. This gentleman, who had had many opportunities of seeing the rinderpest, had no difficulty in recognising this disease in the malady in question, and, with a view to arrest its further progress, he recommended to the superior authorities the adoption of those measures which experience had shown to be best calculated not only for this, but to cause its quick extermination; namely, to slaughter the sick animals, isolate those which had been exposed to the contagion, and establish a *cordon* around the infected places. These measures were put in force at once, and soon had the effect of arresting the further progress of the malady, when some young physicians, who had had an opportunity of making, for their instruction, some *post mortem* examinations of the cattle, thought that they recognised in the affection an analogy to that of the *typhus abdominalis* of man. They therefore communicated their opinion to some members of the faculty of medicine at Prague, who, after making several autopsies, came to the same conclusion. A report was accordingly sent to the government setting forth that the malady was not contagious, that it could rise spontaneously amongst the horned cattle of the country by other influences than those of the contagion, and that the means which the government had adopted were not only useless but vexatious. As the faculty had great authority in all sanitary matters, the government, although it did not entirely remove the restrictive measures, still did not enforce them with its usual rigour; the result of which was that in a few weeks the malady had extended into several other circles of the kingdom, committing such dreadful ravages, that the Austrian government took alarm, and forthwith sent M. Eckel, Director of the Imperial Veterinary Institute, into Bohemia. He at once found that it was the rinderpest, and recommended the rigorous enforcement of the former measures, the result of which was that in six weeks or two months afterwards the malady had entirely disappeared in the kingdom of Bohemia."

Incubation.—Like small-pox, and many other affections common to man and animals, rinderpest lies dormant for a time after the infection has entered the organism. This period is found to vary in different diseases, and also in the same disease at different times, as well as with animals which belong to different zoological

classes. It is influenced by many external circumstances, such as the manner in which the infection is received, the heat of the weather, temperament of the animal, freedom from other diseases, peculiarity of constitution, &c. None of these causes can be said, however, to prevent the outbreak of the malady, although some of them may retard, and others facilitate, its appearance. During the incubative period, the animal gives no indication of ill-health, and only does so when the disease is about to declare itself.

The time that the poison of the rinderpest lies dormant is also found to vary; many animals sickening on the seventh day after exposure, and others not until the thirteenth or fourteenth. Some are said even to pass to the twentieth day before giving evidence of the malady. Such cases are few and may possibly depend on secondary exposure to the infection rather than on so great a variation in the periods of incubation. These secondary exposures are not unfrequently entirely overlooked, and especially with such an affection as the rinderpest, the infecting materials of which can be conveyed by indirect as well as by direct means. It must not be forgotten, also, tthat it is a rule or law belong to this class of maladies that if an animal passes over the usual period of incubation, it is secure against an attack, and in order to become the victim of an infection, it must be a second time exposed to the influence of the morbific matter. Direct and well-considered experiments are wanting with regard to the incubation of the pest, and these we had no opportunity of making while on our mission. No doubt, however, should be allowed to remain on a point like this, as on it depends the security to be afforded to every country which is contiguous to the steppes of Russia. Austria, which suffers almost annually from this disease in some parts of her dominions, has an especial interest in the question, and should lose no time effecting its complete and satisfactory solution. In our opinion Austria should appoint a commission of scientific men, and vest it with some of her absolute power to conduct experiments and take every necessary means of determiniug the point in a conclusive manner, for the benefit of other countries as well as herself, and she will then both deserve and receive the thanks of the world.

Spontaneous Origin.—The steppes of Russia are the home of the rinderpest, and here it may be said to hold almost undisputed sway, little being done by the Imperial Government to stay its ravages. Here also, as as has been elsewhere stated, it is alone regarded as having a spontaneous origin, but it is very probable that a scientific investigation would show that it spreads only from infection directly or indirectly communicated to the numerous herds of cattle which inhabit these extensive plains.

Doubtless every disease has had its place of origin, and in it there may exist persistent causes which keep alive, so to speak, the curse of sin. Such causes may possibly be found on these vast plains of Russia; and if so, here would be the natural habitation of the pest. Be this as it may, it is certain that in those countries which are contiguous to the steppes the malady has no such origin, and its appearance in them is invariably associated with the recent introduction of steppe cattle, and generally in the ordinary course of traffic.

No disease which we have ever studied appears to be governed by such precise laws as this, with regard to the means of its extension; and it is difficult to believe that it should spread by infection alone throughout Europe, and not be subject to the same law in the steppes. Supposing the fact, however, to be as asserted, it is evident that peculiarity of breed is not of the causes on which it depends. Large numbers of steppe oxen are met with out of Russia, and in Galicia we saw many which were used for the purposes of husbandry, and these are never known to be the subjects of the pest, unless brought under the influence of the infection. Besides, the Hungarian, Italian, and steppe cattle are all, from their great similarity, evident descendants of the old Roman ox, and yet it appears that in but one of these has rinderpest a spontaneous origin. Hungarian oxen are even said to be less susceptible to the disease than the other breeds met with in the Austrian dominions, and to bear up better against it, so that the percentage of deaths among them is much less than among others.

Exertion has been assigned as the cause of the appearance of the malady, but like breed this too is powerless with all cattle except with the steppe. We do not regard, therefore, the fact of the breaking out of the pest among steppe cattle at the end of a journey as a satisfactory proof that the exertion they have undergone is the cause.

When we observe a malady to be capable of being communicated from animal to animal by innumerable means of conveying the *materies morbi*; and when we take into account the varying susceptibility of animals to the immediate action of this matter, and also the further circumstance of its remaining dormant in the system for a fortnight, or possibly a longer time, we see many reasons for withholding our assent, without greater experience in the disease, to the opinion that the pest has a spontaneous origin in the ox of the steppes.

General Symptoms of the Pest.—When the animal sickens, the affection will be recognised by almost continuous spasmodic twitchings of the voluntary muscles of the body, more particularly those of the neck and shoulders, and of the hind quarters. These twitchings are accompanied by tremors, which are more or less generally diffused, and which interrupt the regularity of the spasms, and give to the animal an appearance of suffering from exposure to cold. The coat stares, and the patient stands with its back arched and its legs gathered together under the body, but does not seemingly suffer much acute pain. In the course of a few hours rumination is suspended, and the appetite fails, but water will generally be partaken of almost up to the end.

The temperature of the body is variable, a slightly increased warmth of skin existing at the beginning of the illness, which soon, however, gives way to chilliness of the surface, and this again to a death-like coldness of the ears, legs, and horns, as the malady advances to a fatal termination. The pulse is scarcely disturbed at first, unless the attack is a severe one; when it quickly rises to 70 or more, but wants tone in its action. In all ordinary cases it becomes gradually more frequent in number, but less in force, and in the latter stages can only be felt at the heart.

The respiration is but very little altered at the commencement; it rarely becomes difficult, and was never painful in any of the cases we witnessed It sometimes rises to 30 on the second day. The contractions of the abdominal muscles are often interrupted in their rhythmical action by the spasmodic twitchings, which give a singular motion to the animal's flanks, and has led some observers to speak of a difficulty of breathing as being invariably present. A discharge comes on early from the nostrils, which has many of the characters of ordinary mucus, but, when carefully examined, will be found to contain flocculi of lymph. A slight cough is also present in some cases; but it cannot be heard except one is near to the patient, when it imparts a singular and almost indescribable sound to the ear.

The expression of the countenance does not denote much acute suffering, and the eyes are without any dull appearance, except in the advanced stages of the malady, when the lids are found to be drooping as in sleep, and

the ears to be a little lopped. The vessels of the conjunctival membrane are almost without turgescence; but a discharge in most cases comes from the eyes, which accumulates in a yellow jelly like mass at the inner angle, and when examined is likewise found to be composed principally of lymph.

The bowels are but little disturbed at the very beginning of the disease; but the feculent matter, almost unaltered at first in consistency, is soon passed in increased quantity, and in the course of the second day diarrhœa sets in. This diarrhœa is presently followed by dysentery, which continues to the end. The evacuations are not particularly offensive, but they are remarkably fluid, of a dirty yellow colour, and mixed with numerous small flocculi of lymph. Occasionally a little blood stains the evacuations, and tenesmus is also present in some cases. The abdomen becomes much pinched in, and the animal's strength quickly fails him He now keeps mostly recumbent, and rises very reluctantly. If made to move he staggers, and often falls for want of strength. The spasmodic twitchings now *begin to diminish*, and for some hours before death they have entirely passed off.

A sickly smell attends the patient, but there are no disengagements of gaseous compounds into the areolar tissue, nor any other indications of the decomposition of the tissues which have been spoken of by some writers. In short, the animal dies, apparently, and almost without convulsions, from pure prostration of the vital powers.

In those cases which recover no pustules have been observed as forming on the skin, nor any desquamation of the cuticle or fall of the hair. Nor have any ulcers of the eyes, nostrils, or muzzle been noticed in either extreme or protracted cases.

One of the most favourable indications of a return to health is a less frequent evacuation of fluid from the intestinal canal, and the dejections possessing somewhat of a feculent character. Such animals soon acquire a more lively appearance, look about for some tempting kind of food, and will slowly begin to ruminate. The pulse acquires more tone, the temperature of the body rises, and the respiration becomes natural, but the diarrhœa will not unfrequently continue for seven or eight days.

Duration.—In all cases which tend to a fatal termination, the animals rarely live beyond the fourth day after the symptoms have shown themselves, while very many of them will sink as early as the second day. The greater number, however, die on the third day from the attack. In those which recover, some diminution in the severity of the symptoms usually takes place on the third or fourth day, and if the patient survives this time, even should the symptoms not abate, it is regarded as a favourable indication of ultimate recovery. The return to perfect health is rarely effected in less than three weeks, but much will depend on the age and constitution of the animal, as likewise on the amount of structural disease in the mucous membranes of the alimentary canal, and not a little also on the care and attention which are given the patient.

Percentage of Deaths.—If the pest be allowed to take its natural course for only a few days, it will be found that the deaths not unfrequently number 90 *per cent.* Steppe cattle are, however, said to bear up better against the affection than others, so that about one-half of them will sometimes recover. Speaking, however, in general terms of the different breeds of cattle, as well as of the different circumstances under which they are placed, the mortality will be found throughout Europe to range from 75 to 80 per cent. Fat animals, and those which are well cared for, are found to bear up very badly against the disease.

Post-mortem Appearances.— The morbid lesions produced by the pest will be found centred in the mucous membranes, which are more or less affected throughout the entire body. Commencing an examination at the mouth, it not unfrequently happens that many of the conical papillæ which stud the body of the tongue will show here and there, at their bases, their vascular and epithelial coverings to be broken up by the ulcerative process. The root of the tongue, fauces, and *velum palati,* are also similarly implicated to a greater or less extent, while their follicles are filled with effused lymph, giving to the parts an appearance as if dotted over with some yellow pigment. Some of the follicles are likewise ulcerated, but the major portion are merely distended with lymph.

The tonsils are in a similar condition; and when a section is carried through their long diameter, large portions of lymph can be drawn from their ducts, the yellow colour of which, interspersed in lines along the course of these passages, contrasts strongly with the red substance of the organs. Much turgescence of the vessels of the Schneiderian membrane, with points of ulceration and shreds of lymph, are met with, more particularly about the posterior nasal opening, and base of the vomer. These lesions, however, rarely extend beyond the middle portion of the *septum nasi.*

The pharynx presents the same appearance, but the œsophagus is healthy, as is both the rumen and reticulum in most cases. In some few instances the epithelium readily peels from off the inner surface of these stomachs, when the vessels beneath are found to be turgid with blood. The rumen invariably contains a fair quantity of ingesta in the state usually met with in healthy animals. The omasum is without structural change, or at most its mucous surface presents an analogous condition to that of the rumen and reticulum. The contents of the omasum are frequently so dry and hard that they can be rubbed to powder between the fingers. This has been considered by many continental pathologists as a peculiarity attaching to this disease, and hence the term *Löser dürre* has been given to the malady. In three consecutive *post mortem* examinations, as well as in many others, we found that no alteration, either of the omasum or of its contents, existed which was incompatible with perfect health

The mucous membrane of the abomasum is always highly congested, more especially towards the pylorus; and its follicles are in an analogous state to those of the fauces, *velum,* &c. The duodenum, jejunum, and ileum are similarly affected, but to a greater extent. These intestines often present a bluish aspect on their serous surface, but which is entirely due to the turgescence of the vessels of the mucous membrane, which being seen through the other coats, gives a greater depth of colour to it than natural. Peyers glands are not invariably diseased, but, like other follicular openings of the digestive canal, they are often covered with layers of lymph, beneath which ulceration is occasionally observed, but more frequently the surface is healthy, although turgid with blood.

The chief ravages of the disease, as we have met with them, are in the large intestines. The blind end of the colon—the cæcum—was, in one case in particular, ulcerated over several inches of its inner surface, that is, numerous small and distinct ulcers existed, which had evidently had their origin in the follicles of the mucous coat. Thin deposits of lymph, varying in size from that of a pea to the end of the finger—scabs as they have been designated—usually stud the large intestines almost throughout their whole extent. They are of a dirty yellow colour, and adhere with tolerable firmness to the mucous membrane beneath. In some places ulceration is found to be going on in the membrane; in others this destructive process has ceased,

and the healing one commenced, and in most no change of structure can be observed. The terminal portion of the rectum is generally implicated to a far less extent.

The substance of the liver is healthy; the gall ducts, however, contain layers of effused lymph; and sometimes to an amount sufficient to block up the passages. The gall bladder is filled with bile possessing its ordinary characters, but the inner surface of the bladder is not unfrequently in precisely the same state as the mucous membrane of the large intestines.

The kidneys are healthy, and the urinary and generative systems apparently unaffected.

The larynx is occasionally slightly ulcerated, particularly on the edge of the arytænoid cartilages. No ulceration, however, has been seen by us throughout the whole extent of the windpipe and bronchial tubes; but thin layers of effused lymph lying in close contact with the mucous membrane are almost invariably present. The lungs are healthy, of a normal colour, and often remarkably free from congestion. Their serous membrane is also unaffected.

The heart is healthy, occasionally rather flaccid, and without blood in its cavities. The blood in all the vessels is *fluid*, evidently from loss of its fibrine. It is also darker in colour than ordinary venous blood. The brain and spinal marrow give no evidence of structural change; but an increased quantity of fluid is often found in the ventricles of the brain, and especially in the upper part of the *theca vertebralis*. The flesh is firm, of a good colour, and has but little tendency to pass quickly into decomposition; indeed, we have not unfrequently seen it in a state fitted for food.

Pathology.—It is difficult to speak with certainty of the true nature of the rinderpest, but it is evident that the morbific matter on which it depends, having entered the system through the medium of the organs of respiration, soon acts upon the blood, by converting some of the constituents of that fluid into its own elements; and that, while this process is going on, the animal gives no recognisable indications of being the subject of the malady. This period constitutes the incubative stage of the disease.

The blood, having thus become contaminated, its vitality impaired, and the poison augmented a thousandfold within the organism, the brain and nervous systems, as the centres of sensation and motion, have their normal functions necessarily and quickly interfered with, and hence one of the earliest indications of the disease is a spasmodic twitching of the voluntary and other muscles of the body.

The malady has now arrived at a stage when nature makes a bold effort to rid the system of the poison, and in doing this the force of the morbific matter, so to speak, falls with more or less severity upon the mucous membranes throughout the entire body. Effusions of lymph—the fibrine of the blood—take place into the follicles of the mucous membranes, as an effect perhaps in part of the overtaxing of these grand excretory organs, and partly because the fibrine itself is charged with the *materies morbi*, and has probably also lost some portion of its vitality, which renders it unfitted to remain in the vessels. Dark-coloured blood, and which remains fluid even after death from its defibrination, now flows in the vessels; and dysenteric purging also sets in, under which, as a rule, the animal quickly sinks.

If, on the contrary, the *vis vitæ* should be sufficiently powerful to withstand so great an exhausting process, then the poison being cast off, and principally by the digestive canal, the patient slowly rallies, and the functions of the organism are gradually restored. Healthy fibrine again supplies the place of that which was lost, so that the blood will now clot when removed from the vessels, and be once more brought into a state to support the vitality of the prostrated organs.

Ulceration of the mucous membranes, commencing in the follicles, may attend these processes, but it is not a necessary pathological condition of the pest. It is rather to be regarded as a sequence depending for its existence on the amount of the contamination of the blood, the duration of the disease, and the diminished strength of the vital forces.

In all this we have a great similarity to the pathology of the small-pox, but in that disease the external skin is the principal focus of the malady; while in rinderpest the mucous membranes or internal skin are its chief seat. Small-pox frequently proves fatal before the local symptoms are well established; and so, indeed, does rinderpest, from the great amount of morbific matter with which the system is charged.

Names given to the disease.—Of all the terms which have been given to this malady, there is none which we are willing to adopt in preference to "RINDERPEST." It is the one which we have employed throughout this Report, although it may be thought that it is too general in its application, and deficient also in explicitness, to be selected in preference to others which set forth something of the nature of the disease. The term nevertheless explains that the affection is a true *cattle plague;* and, besides this being the one which is used throughout Germany, it is thoroughly understood in nearly every European state—a fact which gives a value above many others.

"STEPPE MURRAIN," although it tends to throw some light on the chief location of the disease, fails to take cognizance even of the kind of animal which is the subject of it, and leaves the pathology entirely unexplained.

"CONTAGIOUS TYPHUS" is far from being appropriate, notwithstanding that the disease has some characters which are common to the typhus of man. The differences which are observed in the duration, progress, symptoms, and results of the two maladies, are far too numerous and important to warrant the pathologist in the adoption of a *definite* term of this kind, and for this reason we have abstained from employing it.

"LOSER DURRE" is, in our opinion, the most inappropriate of any of the names we have alluded to. The hardness of the third stomach, or rather of its contents, which the term implies, is not a speciality attatching to the affection. It may often be present, but it is just as frequently absent. The term directs attention to one particular part of the body as the seat of diseased action; and consequently it often leads to incorrect conclusions. We have seen men of ability, who have been called upon to make *post-mortem* examinations, hesitate to pronounce a decided opinion of the existence of the pest when the third stomach has been found healthy. Hardness or dryness of these contents is common in twenty other diseases of cattle, and in nearly every instance in which it occurs it is but an effect of suspended function of the third stomach, as the cessation of rumination is of the first.

Treatment.—We have very little to report of a satisfactory description of the medical treatment of the rinderpest. Indeed, no attempts at curing the disease are now made, in consequence of the inutility of all the means which have been tried, and the greater risk which is incurred of a still further extention of the malady by the keeping alive of animals which would otherwise be slaughtered at once. The advancement which has of late years attached to the science of medicine would seem to hold out a hope that remedies may be found for this hitherto incurable disease. All experiments, however, undertaken for this object, would have, we believe, but little chance of success, unless they were carried out by,

or under the immediate superintendence of, the professors of the different veterinary institutions of those countries in which the pest prevails.

No definite plan of treatment can be laid down, except it is that of supporting the fleeting vital powers while nature is attempting to rid the system of the poison, and then to endeavour to counteract the ill effects which had resulted. Remedies calculated to promote this end must however be selected for each particular case, and also be suited to each particular stage of the malady.

With these few observations on this part of our report, we shall proceed to give the details in full of several cases of the disease which came under our immediate notice.

CASE 1.

Mention has been made of an aged cow, which was observed, on our second visit to the quarantine stations on May 5th, to be out of health, the symptoms indicating that she was the subject of the malady.

Considering the great fatality and the usually rapid progress of the rinderpest, it is somewhat surprising that its victims should so frequently show such little disturbance to their health at the commencement of the attack. The animal in question was a remarkable instance of this, as well as of the occasional mild character of the disease. The chief indications of illness which she exhibited, when first seen, were tremors of most of the voluntary muscles of the body, but more especially those of the extremities. The *triceps* muscles of the fore-limbs, and the *glutei*, *vasti*, and *triceps* in particular of the hind-limbs, were most affected with these tremblings; besides which a spasmodic jerking of their fasciculi could be detected as coming on at irregular and short intervals. The animal stood with her back arched and legs gathered together under the body. The head was extended, ears lopped, and coat staring. She was remarkably dull, and greatly indisposed to move. Her appetite was impaired, but not lost, as at times she would pick a little fresh grass. Rumination was tardily performed; the action of the bowels unaffected; the breathing natural, and the pulse almost undisturbed. Indeed, had the morning been a cold one—which it was not—nearly the whole of the symptoms that she exhibited might have been ascribed to an exposure to the bleak mountain air.

Towards the after part of the day, the spasmodic contractions of the muscles were more diffuse. The jerking of those situated at the infero-lateral part of the neck was very peculiar, imparting a movement not very dissimilar to the so-called venous pulse. The skin was rather warmer than natural, but the coat was staring, as in the morning. The breathing still continued undisturbed, while a slight but "thick cough" was occasionally heard. The pulse had risen to about 62. It was regular in its action, but beat with somewhat diminished force. There was no injection of the visible mucous membranes present, nor dryness of the muzzle, as seen in active febrile diseases. The Commissioners expressed their decided opinion that this was a true case of the pest, although an unusually mild one, and they therefore gave orders that the cow should be taken from the others, and placed in a separate shed, temporarily erected with the branches of pine trees for the purpose, so that we might watch its progress.

May 6th, 7 A.M.—The symptoms upon the whole have undergone but little change since last evening. The animal still takes a little food, but is equally as dull and dispirited. She shows a disposition to drink freely of water, and would take even more than it is desirable to give her.

8 P.M.—No alteration of importance.

May 7th, 6 A.M.—A change for the worse has come on during the night. The prostration of strength is considerable, and the animal is down, unable to rise. Neither the pulse nor the breathing has, however, undergone much change, the principal being that the action of the heart is rather weaker. She refuses food. Rumination is suspended, and the bowels are rather irritable, voiding large quantities of fæces. The twitching of the muscles are yet present, but mostly confined to the shoulders and neck. The cough is more frequent, and a little mucous discharge also comes from the nostrils. The conjunctiva is uninjected, but the eyes are somewhat intolerant of light. The general surface of the body is chilly, as are the legs, ears, and horns.

On visiting the animals in the evening, we found that a slight diarrhœa had set in during the day; that the pulse had risen to 70, and that increasing weakness was existing. There were, however, but few indications that the attack would terminate fatally, the other symptoms remaining about the same.

May 8th.—The twitchings of the muscles are scarcely to be observed this morning, as is generally the case in the advanced stages of the malady. The diarrhœa is, however, more copious, but yet not alarming; the pulse is quicker and weaker, and only to be felt at the heart. The breathing has now become somewhat increased, but is neither laboured nor difficult. The body is cold, and the animal lies with a drooping head and closed eyes, as in a state of drowsiness, refusing all food, but showing the same disposition to take water.

The Commissioners explained that they considered there was no chance of the animal's ultimate recovery, although the case would doubtless be a very protracted one. They also said that they had decided to have her killed in the after-part of the day, if we had seen enough of the disease in its mitigated form, that we might institute a *post mortem* examination. This arrangement met with our concurrence, and especially as other cases had occurred since this cow was attacked, and which we were busily engaged in watching the progress of, as by it an opportunity would be afforded of seeing the lesions which were early produced by the malady.

SECTIO CADAVERIS.—*Respiratory Organs*.—Mucous membrane of the nasal cavities slightly congested, and covered in patches by a small quantity of a yellowish and somewhat viscid discharge. Larynx healthy; trachea nearly free from injection, but containing some thin shreds of colourless lymph lying in close contact with its lining membrane. Bronchia healthy; lungs perfectly healthy. No effusion in to the thorax.

Circulating Organs.—Heart and its vessels healthy. Blood, dark in colour and but partially coagulated; the coagulum being very soft.

Digestive Organs.—Tongue healthy; fauces and velum congested; pharynx and œsophagus, healthy. Rumen healthy, containing a fair amount of ingesta. Reticulum and omasum likewise free from structural disease, and no hardness of the contents of the omasum (löser dürre). Slight efflorescence of the mucous membrane of the abomasum in patches was present, while nearly throughout it was likewise dotted over with yellowish points, produced by effusions of lymph into its follicles. The contents of this stomach were fluid, in which floated some shreds of lymph. The duodenum, jejunum, and ileum were nearly free from disease, presenting only here and there a similar state of the mucous membrane to that of the abomasum. The cæcum, colon, and rectum were filled with fluid fæces; but their mucous membrane was, on the whole, free from change.

Liver, healthy in substance; the gall-ducts were, however, enlarged and thickened in their coats from chronic disease, associated with depositions of osseous matter. The gall-bladder was filled with bile, and its mucous membrane was likewise studded with effusions of lymph into its follicles analogous to the abomasum.

Pancreas and Spleen.—Healthy.

Urinary System.—Kidneys, bladder, &c., free from disease.

Nervous System.—Brain, spinal marrow, and their membranes healthy in so far as their structural appearance was concerned.

CASE 2.

May 6th.—After giving our attention this morning to case 1, we went over to Zabrzez to inspect the cattle, which we saw at M. Berl Krumholz's farm at the time of our first visit. Here we found that a young bull, two years and a half old, and one of the nine animals formerly referred to, as still being in quarantine, was the subject of the malady. The animal in question had only been observed to be unwell early this morning, being twelve days subsequent to the death of the last victim. The symptoms now present were spasmodic twitchings of the muscles, more particularly of those of the neck and shoulders. The spasms succeeded each other with great irregularity, but numbered on the average about ten in the minute. They were likewise accompanied with slight shiverings of the entire body. The skin was warm, as were also the legs, horns, and ears. The back was arched and the animal stood with his legs gathered under the body, but frequently shifted his position as if in pain. His countenance, however, was more animated than is generally seen, even in the early stages of the malady. There was a little turgescence of the vessels of the conjunctiva, but no intolerance of light. A slight mucous discharge flowed from the nostrils, and a short,

but nearly inaudible cough was present. The breath was sweet, and the respiration scarcely disturbed. The pulse was increased to 80, and had more fulness than is usual in these cases. All desire for food had ceased; rumination was suspended, and the bowels were in a relaxed condition.

6 P.M.—The symptoms are somewhat aggravated. The animal is down and is more depressed than in the early part of the day. Diarrhœa has set in, and some tenesmus is present. The twitching of the muscles is more violent and frequent. The cough is increased, as is the discharge from the nostrils; the pulse, however, remains the same.

May 7th.—There is no great change in the general character of the symptoms this morning. The diarrhœa is, however, more copious. The pulse is weaker, but its number is not increased. The breathing is but little altered. The cough is of the same mucous character. The nasal discharge is thicker and contains shreds of lymph. The eyes are heavy. The animal keeps laid a good deal, and when down appears sleepy. The spasmodic contractions of the abdominal muscles, which at times are considerable, give a peculiar tremor to the whole body and interrupt the rhythmical action of inspiration and expiration. Pressure on the spine augments these spasms as well as those of the muscles of the neck and limbs. He refuses all food, but takes a little water.

6 P.M.—Except that the animal is weaker, and the alvine evacuations more fluid, there is no change which needs to be specially reported.

May 8th.—The spasmodic twitchings are less diffused than yesterday and not so severe. The pulse is, on the contrary, more rapid, and so weak as to be felt with very great difficulty except at the heart. The respiration is also increased, and now numbers twenty-six in the minute; it is not, however, laboured. The cough although frequent is scarcely audible; it has the same mucous character. The muzzle is moist, but cold, as are the extremities and horns; while the surface of the body is yet warm. The diarrhœa has passed into dysentery. The evacuations are now of a dirty-yellow colour, and remarkably fluid; they contain flocculi of lymph, and are occasionally streaked with blood, but are not particularly offensive. A sickly smell attends the patient. The eyelids are drooping, and a thick jelly-like mass of a pale straw colour has accumulated at the inner angle of the eyes. This is evidently composed chiefly of fibrine; yet the vessels of the conjunctiva are not turgid with blood. The animal has a greater disposition to keep laid, and often while recumbent turns the head to the side as if suffering slight abdominal pain.

May 9th.—The spasmodic twitchings and the tremors are no longer to be recognised, having entirely passed away. The prostration of strength is very great. The dysenteric purging continues unabated in severity. Tenesmus is present, and the evacuations are now very offensive. The abdomen is much pinched in. The respiration remains the same in number, and is occasionally accompanied with a nasal blowing-like sound. The discharge from both the nostrils and eyes is augmented in quantity: the eyes, however, still retain their transparency, and the blood vessels are but slightly injected. The pulse is not weaker than yesterday, but upon the whole a little more distinct. The ears, horns, and extremities are still a little warm. The animal takes a small quantity of water, and appears to be free from any acute pain.*

* The Commissioners decided to-day upon slaughtering the remaining eight animals in the quarantine, as two or three of them were giving indications of approaching illness. They also had in view the raising of the *cordon* at an earlier date than it otherwise could be, supposing the malady was allowed to take its ordinary course; for, as elsewhere stated, it has to be maintained for *twenty-one* days after the death or the killing of the last animal. The chief object in keeping up the *cordon* for this length of time is to prevent the possibility of a fresh outbreak. No newly-purchased cattle are therefore allowed to come on to the farm, nor is any labourer, or other person, allowed to leave it. No straw or fodder of any kind is permitted to be removed: in fact, all the details are as rigorously enforced during these three weeks as while the disease exists.

The resolve of the Commissioners afforded us the opportunity of witnessing the form of valuing the cattle *for slaughtering* on the part of Government, their real value being greater than the estimated one. For this purpose a jury of three persons was summoned, consisting of the Burgomaster of the village and two other inhabitants conversant with the worth of cattle. They were not, however, allowed to come within 200 paces of the line of the *cordon*. The non-medical Commissioner, M. Rucki, took his seat on a table placed on the line, and being furnished with writing materials, noted every particular of the transaction. The cattle were then brought one by one to within a short distance of the Commissioner, to be inspected by the jury, who asked a great variety of questions relating to their age, breed, and use for feeding, milking, or working purposes; which being satisfactorily answered, they made their award.

		£	s.	d.
The first, a young heifer, was valued at about, in	English money	4	0	0
The second, also a heifer	do.	4	0	0
The third, a milking cow	do.	7	0	0
The fourth, a young steer	do.	3	6	0
The fifth, an older steer	do.	4	18	0
The sixth, a young bull	do.	4	0	0
The seventh and eighth, two heifers	do.	8	16	0
Total		£36	4	0

The skins of the animals were next valued at 8s. each for the larger ones, and 6s. the smaller, which sums, we were informed, would be deducted from the gross amount, the proprietor being allowed to dispose of them as he thought fit, after they had undergone a disinfecting process, under the immediate superintendence of the Commissioners. This part of the ceremony being ended, the animals were led away to be slaughtered and buried, when the jury were permitted to approach the table to sign their award. One only of the three could write, namely, the Burgomaster, and he received authority to sign for the others. The appearance of these men was certainly picturesque, if not very prepossessing. They were very scantily clad, having on scarcely any clothes except a long coat made of a coarse and thick woollen material of a dirty-white colour, and reaching to below their knees. The Burgomaster differed but little from his compeers, excepting that he wore a leathern girdle, furnished with a pocket, around his waist, in which he carried his money, and of which, little as it was, he appeared very proud. Their legs were enveloped in pieces of linen tied on with string, and their feet were protected by roughly-made sandals, having very thin leather soles, being apparently of their own manufacturing.

May 10th.—The symptoms are somewhat diminished in severity this morning, leading to the hope that the animal may possibly rally. The dysenteric purging is less in quantity, and the evacuations also are less frequent. The breathing is more tranquil, and the cough more audible. The pulse has sunk to 70, and has an increased tone. Each rising of the artery is accompanied with a peculiar jerking action. The discharge from the nostrils and eyes has not undergone any material change. The extremities and surface of the body are warmer, and the animal is evidently freer from suffering. He lies less; takes freely of water, and shows a little disposition to pick some fresh green clover, a handful of which we gathered for him.

May 11th.—Scarcely so well to-day. Some blood is occasionally passed with the alvine evacuations. These are still fluid, have a fetid smell, are of a pale colour, and contain numerous shreds of lymph. The abdomen is more pinched in. The pulse is rather quicker, as is the breathing, the expirations being at times accompanied with a slight grunt. The discharge from the eyes and nostrils is less, but the cough is more frequent. He has, however, eaten a little clover and drank some water, and stood up at intervals for a longer time than before.

This change in the symptoms made us most desirous of watching the case to its close, but the commissioners ordered that the animal should be killed forthwith, as they saw no hope of recovery, and were anxious to remove the *cordon*, there being no cattle left on the premises, except the Steppe oxen, mentioned as having some weeks since recovered from the pest.

Post-mortem Examination.—On removing the skin, the muscles were found of their usual colour and integrity, and the areolar tissue throughout was free from congestion. Commencing the examination of the internal organs at the nostrils, the Schneiderian membrane was observed to be much congested, more particularly that portion of it which is continued into the *posterior nares*, where it was extensively ulcerated. This ulceration could be traced from thence to the free edges of the *velum palati*. In places it was concealed by a thick layer of lymph, which adhered with tolerable firmness to the membrane beneath. The larynx, trachea, and bronchi were free from disease, as were also the lungs. The heart was healthy. It contained within its ventricles a small quantity of blood, which was *partially coagulated;* the coagulum being very soft.

The tongue was healthy, as was also the pharynx; but the ducts of the tonsils were filled with effused lymph, the sur-

rounding vessels being turgid with blood. The œsophagus, rumen, and reticulum were in a normal condition. The contents of the omasum were rather dry from retention, but no structural change had taken place in the stomach itself. The mucous membrane of the abomasum was slightly ulcerated in small-sized patches here and there, while nearly throughout its follicles were distended with lymph, more especially towards the pylorus.

The mucous membrane of the small intestines was congested, the bowels themselves containing numerous flocculi of lymph. Several of Peyer's glands were ulcerated. In some, arrestation to this process had taken place, and the healing one had begun. All these glands were covered more or less with a thickish layer of effused lymph. The mucous membrane of the cæcum was extensively ulcerated at the blind end, and throughout the intestines it was thickly beset with scabs of a dirty yellow colour. Many of these scabs—the product of lymph effusions—covered surfaces in which no disease could be detected. Other of the scabs had ulceration going on beneath them, while under several the healing process had commenced. They varied in size from that of a small pea to the end of the finger. They were also of different forms and thicknesses.

The colon was in a similar condition to the cæcum, as was likewise the rectum to within a few inches of its termination. These intestines contained no fæces, but were filled with a fluid of a yellowish colour, in which floated many shreds of lymph. The liver was healthy, but the lining-membrane of the gall-bladder was in a precisely similar condition to that of the large intestines. The kidneys were pallid, but unchanged in structure. The bladder and genital organs were perfectly healthy. The brain and spinal marrow gave no evidence of structural change, but effusion of serous fluid had taken place into the theca vertebralis.

Case 3.

May 7.—The animal, a very poor and weak heifer, was reported by the sentinel on night duty at the quarantine in Kamienica to have been observed early this morning to be giving indications of the disease. The symptoms noticed by us on our visit consisted in chief of spasmodic twitchings of the muscles of the neck and extremities in particular, associated also with general shiverings of the body at irregular intervals; pulse 60, having a sharper beat than natural; a loathing of food; suspension of rumination; grinding teeth; lax and copious fæces; depressed countenance, drooping eyelids, lopped ears; staring coat, arched back, and chilly surface of body; the animal standing with its legs gathered together under the belly. The respiration was, however, undisturbed; the vessels of the conjunctiva uninjected, and the muzzle moist. No tenderness along the course of the spine was evinced on the application of pressure.

At night, with the exception of increased weakness and the passing of more fluid fæcal evacuations, there was no material change in the symptoms.

8*th*.—The pulse now numbers 65, and has lost its sharp beat; the breathing is a little quickened; the diarrhœa has passed into dysentery; the animal's appearance is very dejected; a discharge flows from the nostrils and eyes; the coat is staring; the spasm of the muscles more intense; the extremities and body are cold; and the prostration of the vital powers very considerable.

9 P.M.—The pulse has risen to 75, and can be felt only with difficulty in the arteries; the breathing has become very much quicker during the day, and now numbers 24 in the minute; the dysentery is profuse; tenesmus is likewise present. The other symptoms remain about the same as in the morning.

9*th*.—The symptoms are all increased in severity, excepting that the tremors have nearly disappeared; the abdomen is much pinched in; small quantities of blood stain the alvine evacuations, which are likewise very fœtid; the pulse is remarkably tremulous, and the respiration is short and quick. The animal will, however, take a little water to drink.

10*th*.—During this day she struggled on against the disease, but sunk about midnight, being far too weak to rise for several hours before death.

Port mortem—eight hours after death.—No congestion of the superficial vessels, nor change in the colour of the flesh, was observed on the removal of the skin, nor was there but little tendency to decomposition of the body. The blood, however, was *fluid* and of a dark colour in all the large veins. Ulceration had commenced in several places on the dorsum and root of the tongue, especially around the bases of the conical papillæ. The fauces, *velum palati*, pharynx, larynx, were also ulcerated here and there in patches of about the size of a shilling; the mucous membrane of the posterior nasal opening was intensely reddened, and studded with yellowish-coloured points from effusions of lymph into its follicles; the ducts of the tonsils were also filled to repletion with lymph. The lining membrane of the windpipe and bronchial tubes was but slightly congested, but in many places it was covered with *layers* of effused lymph. The substance of the lungs was healthy, as was their serous covering. The heart was rather flaccid; no blood was found in its ventricles.

On opening the abdomen some petechial spots were found on the omentum, otherwise the serous membrane was free from any vascular injection. The fourth stomach, and also the small intestines, presented a dark-coloured condition of their outer coat; but this was ascertained to depend on the congested state of their mucous lining as seen through the other coats. The first stomach—rumen—was free from disease; but its epithelial lining could be readily peeled off in places, doubtless from changes which had taken place since death. This stomach contained some rather dry ingesta. A similar state of things was met with in both the reticulum and omasum, but no true löser dürre existed. The lining membrane of the fourth stomach—abomasum—was intensely reddened throughout, and its follicles crammed with lymph. Effusions of lymph adhered in many places, as scabs of a dirty yellow colour, to the mucous membrane of this stomach.

The duodenum, near to the pylorus, was in a similar state to the fourth stomach, as were the jejunum and ileum in several detached places along their course. Peyer's glands were free from ulceration, and several of them had every appearance of health. The mucous membrane of the large intestines was ulcerated here and there; while in other parts no change of structure could be detected. These intestines contained much mucus mixed with shreds of lymph. The liver was healthy in its substance, and the gall bladder was filled with a greenish coloured bile. Its lining membrane was free from disease, but thin bands of lymph could be drawn from out of many of the large biliary ducts. The urinary and genitive organs gave no evidence of disease. The brain and spinal marrow were firm, and presented no structural change; but an unusual quantity of fluid existed both in the ventricles of the brain and also in the upper part of the theca vertebralis.

In consequence of the occurrence of this case, and of Case No. 1 in the same quarantine station, the Commissioners determined to slaughter the rest of the cattle, consisting of five, reserving only the animal in question for our special purposes. This resolve was taken on May 8th, and was somewhat hastened by the circumstance that all the animals were in very low condition and of little value, being the property of small farmers but one degree superior in position to the peasants. The greatest difficulty also existed in procuring sufficient food for them; and poor women, the wives of the proprietors, could be daily seen standing in the mountain streams for hours together, up to their knees in water, with scarcely clothing sufficient to cover their persons, washings couch grass, which had been picked from off the land in order to feed these cattle. The step was, doubtless, rendered necessary by the circumstances; it was nevertheless most painful to witness the lamentations of the poor women on its being carried into execution.

Shortly after the removal and slaughter of the animals, the quarantine station was set on fire, and soon razed to the ground.

Case 4.

On the evening of May 9th, information was brought to the Commissioners that a fresh outbreak of the malady had occurred in the village of Kamienica. On hearing this, we were almost immediately on the spot; and found that a cow, one of five of the herd, was fast *sinking from the disease*. It was evident that she had been ill for at least two or three days, but had not been reported. The Commissioners expressed much dissatisfaction at this, and immediately took possession of all the animals, and sent them off the premises into quarantine. The key of the stable in which the cow had been standing was delivered over to the custody of the military, and the *cordon* established. We may here repeat, that if the proprietor conceals the fact of the appearance of the pest among his cattle, or has been in any way instrumental in bringing it among

them when it prevails in the locality, the entire loss which he may sustain falls upon himself, the Government refusing to make any allowance even for those that are ordered to be killed by their officers. This course was, therefore, the one adopted.

The most marked symptoms shown by the animal in question were—a profuse dysenteric purging; indistinct pulse; rapid breathing; surface of body and limbs cold; eyes sunk in their orbits; discharge of mucus, mingled with lymph, from the eyes and nostrils; staggering gait, and great prostration of strength. Indeed, on the way to the quarantine station, she fell twice, although the distance was not more than three hundred yards. It was also with much difficulty that she was made to rise. In this condition she lingered on for about eight hours, when death put an end to her sufferings.

The principal lesions met with, in making the *post mortem* examination, were—ulcerations at the root of the tongue and extensive turgescence of all the surrounding vessels; tonsils loaded with effused lymph, and also all the follicles of the fauces and contigous parts; large shreds of lymph existed in the windpipe and bronchial tubes. The heart was pale and flaccid. The abomasum was not so much affected as in other cases we have quoted, nor was any portion of either the small or large intestines. Where diseased, the lesions of these viscera were precisely similar to those already described. The mucous membrane of the gall-bladder was extensively diseased, but the ducts of the liver were free from deposits of lymph. Excess of fluid existed in the ventricles of the brain and also in the spinal sheath. All the organs which have not been specially named in this case were free from strictural change.

Cases 5, 6, 7, 8.

The animals which formed the subjects of these cases were the companions of Case 4. Three of them exhibited the usual symptoms which are seen at the commencement of the pest on the morning of May 10th, and the other was taken ill during the next day. The character and progress of the symptoms in the first three were about the same as usual, and therefore do not call for any particular remarks. The opportunity was afforded us of watching these animals during the whole of May 10th, the Commissioners allowing them to be kept for that purpose; but on the following day, as soon as the only remaining animal (Case 8) was attacked, they were all slaughtered. The malady was quickly running its course at this time, and doubtless would have terminated fatally in all the animals within a day or two; indeed, in one of them the symptoms were now so much aggravated as to convince us that a few hours would suffice for it to succumb to the pest.

The *post-mortem* examination, which we made in each of these cases, showed that in all essential particulars the morbid changes agreed with those we have already given in detail. Slight differences were observed both in the extent and location of the principal lesions, but these it is unnecessary to describe. Indeed a careful perusal of the cases we have selected for embodiment in this report will, we hope, sufficiently explain these, even to the medical as to the non-medical reader.

Austria.

In our return journey from Galicia we visited Vienna, and went from thence to Munich, Stuttgardt, and Frankfort, with a view of ascertaining, by a personal examination, the state of things in Southern Germany and Rhenish Prussia. In no division of the Austrian dominions, except Galicia, has rinderpest prevailed during the present year; Bohemia, Moravia, and even Hungary have been entirely free from it. The disease existed in several parts of the empire in 1855 and 1856, but was suppressed in the usual manner. It was introduced from Bessarabia, whence it appears that it generally comes.

Some anxiety was shown for fear the malady might be disseminated by the bringing together of animals from different countries at the great Agricultural Exhibition at Vienna, which took place in May last; and the directors of the show, early in April, issued a notice, in which they stated "that the cases of disease which had occurred in Moldavia and Silesia had been confined altogether to the individual animals which had been imported, and that the cattle of the country was free from all murrain." It was further notified, that on the days appointed for the admission of animals for exhibition the transport to Vienna of *cattle intended for the slaughter-house* would not be permitted by railroad, and that the conveyance of the cattle to be exhibited would be effected in perfectly new waggons.

The extent of the last outbreak in Austria, its duration, &c., will be shown by the following official report:

Report on the State and Progress of the Rinderpest in the Austrian Empire in the Years 1855-6.

As the facts set forth in this Report are so explicit, that no comments thereon are required, we may proceed

to state, that after leaving Austria we made our way into

Bavaria.

This country, in common with so many others which we had visited, has likewise been perfectly free from the rinderpest, since from 1813 to 1815; its outbreak at that time being referable to the same cause as in Belgium, &c., namely, the passage of the Austrian army into France.

Professor Nicklas, of the Munich Veterinary School, who had returned earlier than ourselves from Galicia, informed us that pleuro-pneumonia was the chief epizootic disease which prevailed in Bavaria, but that it had not existed to any considerable extent of late years. The sanitary laws to limit its spread are similar to those in other countries, being founded on the fact of the contagious nature of the affection. Animals which have recovered from an attack are marked on their horns with the letters L. S., signifying that they have been the subjects of *Lungenseuche*, it being thought that from the partial disorganization of their lungs they may be the means of spreading the disease for several months after their convalescence.

With regard to rinderpest the laws are very severe; and through the kindness of Professor Niklas, we are enabled to give the following details of their provisions:—

During the continuance of the disease, no cattle, dead or alive, are allowed to be brought across the frontier. Flesh, hides, entrails, horns, hair, and tallow of cattle, and bones, whole or crushed, of any animal, with their hair, wool, or bristles, are also especially prevented crossing by the *cordon;* as are woollen cloths, scutchings of leather, feathers, farmyard manure, hay, clover, straw, and all other descriptions of cattle fodder.

When the disease occurs on a farm, the affected animals are not removed from the sheds, but the apparently healthy are taken to the quarantine station. Each commune is obliged to provide a station of this description, which is built of wood and divided into two parts, one for the doubtful cases, and the other for the supposed healthy.

The Commissioners have the power of allowing medical treatment of the animals, but the veterinary surgeon must remain in the quarantine and receive all he requires at the end of a long pole. All churches, schools, and public-houses of the district are closed so as to prevent the congregating of people together, and remove those inducements which might cause persons to come from infected farms.

On the occurrence of illness among cattle from *other* causes as well as the pest, the Commissioners do not, as a rule, approach the animals; but, standing at a distance, and within sight of them, they arrive at a decision as to the nature of the ailment, frequently ordering some food to be offered as a test of their freedom or otherwise from the malady. In those instances where the Commissioners enter the stable, they are compelled, before leaving, to wash their hands, &c., with vinegar, and have their clothes fumigated with chlorine gas.

All dogs, cats, rabbits, domestic poultry, pigeons, &c., have to be kept in places of security and close confinement. If the disease exist in a village through which a high-road runs, the course of the road is turned, if possible; but when this is not practicable, then a guard accompanies the several travellers who arrive at the boundaries of the *cordon,* to see that they do not go upon an infected premises. The *cordon* is frequently maintained by the peasants; but none are taken for this purpose from an infected village, the selection being made from contiguous villages or farms where the cattle are healthy.

As soon as the malady is observed in a commune, notices are sent to all the surrounding places, that precautionary measures may be immediately adopted by the owners of cattle. Each commune has to provide a place for the burial of the animals which die or are slaughtered, and also a waggon and horses to carry them upon; and, on the disease passing away, the waggon is burnt, and the horses are washed with a solution of chlorinated lime. The place of interment is likewise enclosed, and not allowed to be disturbed for several years.

On an inspection of supposed cases, the animals which give indications of the malady by spasmodic twitchings of the muscles are ordered by the Commissioners to be taken to the burial-ground, where they are killed, and interred with their skins on, these being cut in the usual manner. Occasionally, a special order of the Government permits the removal of the skins, which are then to be subjected to a disinfecting process, under the immediate superintendence of the Commissioners. If but a few cases occur in a large herd of cattle, the Commissioners have the power to suspend the slaughtering of the exposed animals for a few days, in order to watch the result: such animals have a value put upon them, which is paid by the Government. Should no animal fall ill within twenty days from the death or slaughtering of the last case, then the quarantine is raised; but the cattle which have been liberated are not allowed to go near to others until they have been washed with a solution of chlorinated lime. On the discharge of the animals, the quarantine station is razed and burnt.

The Commissioners have to report day by day every occurrence to the Government, and to give the fullest particulars, even to the names of the persons employed at the *cordon*, and the age, colour, sex, &c., of the cattle in the quarantine. The hay on a farm at the time the pest occurred is not allowed to be used for cattle, but must be consumed by horses and sheep.

Such are the regulations existing in Bavaria; in substance they agree with others which have been previously given, but nevertheless we are of opinion that they should find a place in this Report, as several of the details are singularly minute in providing against an extension of the evil. A great difficulty must evidently belong to the carrying out of the requirement respecting the consumption of the hay, and more particularly if the malady should break out in the autumnal period of the year, as then nearly the whole crop would be in store. This regulation, we believe, has been enforced, because it not unfrequently happens that, in accordance with custom, the whole of the hay of a farm is placed on strong floors above the cattle-sheds, and not put into ricks as in England.

Wurtemburg and the surrounding German States.

We learned from Professor Hering of the Veterinary School at Stuttgardt, that, like Bavaria and other kingdoms and States, Wurtemburg had experienced no outbreak of the rinderpest since 1815, and that its existence at that time was also due to the movements of the Austrian army. The regulations of the sanitary police are almost identical with those in force in Bavaria, both with regard to the rinderpest, and also pleuro-pneumonia.

Cattle are reared in large numbers in this kingdom, and are fed for the market principally by the sugar-manufacturers, distillers, and brewers. When fat, they are exported for the supply of the French towns, and Paris in particular. With the exception of Swiss cattle, which are imported for the improvement of the native breeds, very few animals are sent into Wurtemburg from any other country.

Rhenish Prussia.

It could hardly have been expected that this province would be found otherwise than perfectly free from the cattle pest: indeed, in our inquiries of veterinary surgeons, it was somewhat singular that we did not meet with one who had even seen a case of the disease.

Our investigations into the extent of the cattle-pest may be said to have been here brought to a close, and to have shown that even should a revival of the trade in cattle, which had been spoken of in the former part of the report, take place to England through Holland, by means of the Rhine, there would be no risk incurred

of introducing this disease thereby, unless circumstances should unfortunately arise, by which it became as rife as it was in the years 1813, 1814, and 1815.

As the limits which are ordinarily assigned to reports of this description may have possibly been exceeded, we feel that it would not be right to make any observations in addition which are not of a practical character, and therefore we content ourselves by appending a summary of the facts which have been ascertained by us in the fulfilment of our mission.

CONCLUSIONS.

1. That all the countries of Northern and Western Europe from which cattle are exported to England are perfectly free from the rinderpest; and that the only disease of an epizootic or destructive nature which prevails therein is the one known to us as pleuro-pneumonia, which disease has existed here since 1841.

2. That in the greater part of the official dispatches and reports which have been forwarded to the Government, and by them transmitted to the Royal Agricultural Society of England, the Rinderpest has been confounded with Pleuro-pneumonia, "Milzbrand," and other destructive maladies to which cattle are liable.

3. That the Rinderpest is a disease which specially belongs to the Steppes of Russia, from which it frequently extends, in the ordinary course of the cattle-trade, into Hungary, Austria, Galicia, Poland, &c.

4. That whenever circumstances have arisen which called for the movements of troops, and consequently the transit of large numbers of cattle, in Southern and Eastern Europe, and particularly when Russian troops have crossed the frontier of their territory, the disease has been spread over a far greater extent of country.

5. That the disease which has recently prevailed in Galicia—where it was specially investigated by ourselves—as well as in Poland, Austria, Hungary, the Danubian Provinces, Bessarabia, Turkey, &c., is the true Rinderpest or Steppe Murrain of Russia.

6. That with the exception of a few places in the kingdom of Prussia and others in Moravia, near to the frontier of Galicia and Poland, the disease in its outbreaks of 1855, 1856, and 1857, did not extend to any country lying westward of a line drawn from Memel on the Baltic to Trieste on the Gulf of Venice.

7. That, speaking in general terms, Rinderpest has not existed in Central and Western Europe for a period of forty-two years; its great prevalence at that time being due to the war which was being then carried on between the different continental Kingdoms and States.

8. That all the facts connected with the history of its several outbreaks concur in proving that the malady does not spread from country to country as an ordinary epizootic. And that, if it were a disease exclusively belonging to this class, the sanitary measures which are had recourse to throughout Europe would be inefficient in preventing its extension, and consequently that in all probability we should long since have been both painfully and practically familiar with it in this country, as hundreds of our cattle would have succumbed to its destructive effects.

9. That it is one of the most infectious maladies of which we have any experience, and that it is capable of being conveyed from animal to animal by persons and various articles of clothing, &c., which have come in contact with the diseased.

10. That the ox tribe is alone susceptible to the disease; and that the morbific matter on which it depends lies dormant in the system for a period of not less than seven days, and occasionally, according to some continental authorities, as long as twenty days, before the symptoms declare themselves.

11. That an attack of the disease which has terminated favourably renders the animal insusceptible to a second action of the *materies morbi* which gives origin to the pest.

12. That the deaths often amount to 90 per cent.

13. That the malady is one in which the blood is early if not primarily affected; and that subsequently the mucous membranes throughout the entire body become the principal seat of the morbid changes.

14. That the symptoms are in general well marked and quite characteristic of the affection.

15. That all varieties of medical treatment which have as yet been tried have failed in curing the disease; the recoveries which take place having for the most part depended on the *vis medicatrix naturæ*.

16. That no fear need be entertained that this destructive pest will reach our shores. Its present great distance from us would, of itself, afford a fair amount of security; but when we add to this that no cattle find their way from thence, directly or indirectly, to the English market, and also that in the event of the disease spreading from Galicia, it would have to break through hundreds of military *cordons*, one after the other, before it could possibly reach the *western side* of the German states; and, moreover, that for years past commerce has been unrestricted with regard to skins, hides, bones, &c., of cattle from Russia and elsewhere, all alarm, we believe, may cease with reference to its importation into the British Isles.

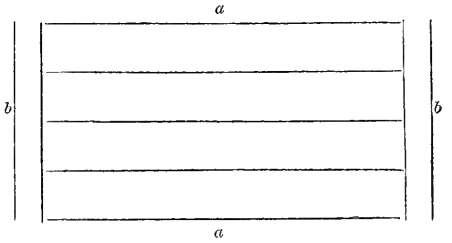
HALKETT'S GUIDEWAY STEAM AGRICULTURE.

Our agriculturists live in the days of innovations. Fast fading from the memory of our farmers—all *slow* as they are said by some to be, but fortunately *sure* withal—is the recollection of the good old times when processes, and the implements by which they were carried out, were handed down from one generation to another, resembling the laws of the Medes and Persians in this, that "they altered not." And, as the influence of those steady times is gradually losing its hold on the minds of our agriculturists as a body, their attention is directed ever and anon by a succession of proposed innovations, fast flowing in, one upon another, to the time coming—by some thought the "good," and by others (who see only evil in any change) ruefully ruminated upon—when innovations will be welcomed as the signs of a healthy progress; and not, as is too often the case now, met with the sneer of the incredulous, and the one-sided investigations of the prejudiced. Unpleasant, truly, is the position of the innovator. He is generally examined as to his purposes and intentions, as if these had for their aim the filching of men's wealth from them, and the subversion of good order and social morality. He is set up to be the fair mark of the carping cabalist, exposed to dull jokes (as if a joke could upset a theory, or be weighed as equal in value with a fact), to be sneered at as a dreamer, and perhaps to have his very sanity placed in doubt. Yet the world is hugely indebted to innovators. It is now reaping the fruits of the thought of schemers, such as Watt, Fulton, Stephenson, and Wheatstone. Sneered at as vain enthusiasts, or denounced as the robbers of the poor man's bread, we find these "innovations" on the practice of their day, unostentatiously yet powerfully at work, clothing the nations, ministering to our wants, and

catering for our luxuries; bearing us to distant lands with amazing speed, against wind and wave; dashing with the fleetness of the race-horse through hill, and along dale; and bidding fair soon to realize the prophetic boast of the Spirit in the play, of "putting a girdle round the earth in forty minutes." Let us, then, treat innovators with all generosity, and canvass the merits of their innovations with all frankness and fairness. Let us view their proposals in the enlightened spirit of those who wished to draw information and derive knowledge from every source, treating none with scorn and indifference because it may present at the first blush features which shock our prejudices, or which run counter to our own knowledge, or supposed knowledge, of facts. It is at all times unsafe to judge by appearances; examination may discover features which were unrevealed to hasty glances. The lamp in the fairy tale looked doubtless a worthless thing; but the magician-merchant knew its worth, and invoked its power. The fabled philosopher's-stone clearly was not thought, by those seeking for it, to be a dazzling gem which, by its lustre would attract any eyes, and reveal its work to any finder; it was evidently a thing to be wearily looked for and closely examined. The glass that glitters in the sun-light is but worthless, after all, and poorly repays the labour of him who traverses fields and overcomes obstacles to gain it; the golden nugget, in its roughened matrix, looks like a lump of molten earth or stone, which may be trodden under-foot or cast aside as worthless. "Examine all things, try all things: hold fast that which is good"—not that which is "old," as some may read it—not that which is "new," as others may translate it; but that which is "good." And this good can only be ascertained by inquiry, by the examination, by the trial which the first part of the text commands.

These remarks, and the conclusions which may be deduced from them, are not, we conceive, inappropriate, in introducing to the notice of our readers a truly startling innovation in agriculture, the peculiar features of which, and their adaptability to practice, the agriculturist is called to examine and canvass. We have said that agriculturists live in the day of innovation; and in view of the probability—nay, the almost certainty—that innovations will increase, not decrease, in number, it behoves everyone to decide how and in what way those innovations shall be received and considered. Too long have agriculturists as a body laboured, and their reputation languished, under the charge, that, as compared with manufacturers and men of commerce, they are slow, and in all things opposed to change, even if that change bring with it improvement. Not here to enter upon the discussion of the question whether this charge be true or not, certain it is that if agriculturists wish "outsiders" to be of opinion that the charge can be answered in the negative, the discussion of "Innovations on Practice" *must* be conducted in a different spirit, and lead to more practical results than has been the "use and custom" in times gone by. Far be it from us to ignore the vast strides which agricultural progress has made during the last twenty-five years, or the wondrous aid which our mechanicians have lent to it in carrying out its various processes; neither do we join in the cry (because wholly false we deem it to be) that agriculture stands still, while manufactures and commerce flourish and spread their dominion wondrously; but what we wish to enforce on the minds of those who think we have arrived at, or at least pretty near to, the promised land of Perfection (not many of which class surely will be among the readers of this journal), that so far are we from this same perfection, that we are simply in a transition state; that we have, in fact, invoked—but not yet possessed ourselves of—that mighty power which has changed the face of commerce; and, further, that Progress does not mean (what some men evidently do think it does) that we are to go on, or up to, a certain point, and stop there; that the meaning of the term, if it has any meaning at all, is a going forward—a moving on; and that consequently it is difficult, if not impossible, for any one to set limits to this progression, and to say "Here it shall go, and no further!"—to change, in fact, the word, and say "Here, up to this point, it shall be progression; then, stoppage!"

Not longer to detain our readers, we hasten to explain the peculiarities of that innovation which forms the subject of this paper—an innovation so thorough in its character, and so subversive of established practice and preconceived notions, that it may well, as some may deem, be ushered in with those remarks which we have ventured above to address to our readers. Last year, at this very time and period, it was our privilege to explain to the readers of this journal another innovation in agricultural practice, and to deduce from it the probability that in process of time the farmer would be called upon to join the somewhat incongruous calling or trade of distiller to his own; and that on the ground of his being enabled thus to become a better farmer. Those who will please to turn to the Supplement of the *Mark Lane Express* of Monday evening, January 9th, 1857, will find, under the title "Agricultural Distilleries," our explanation of the innovation to which we refer. The innovation we have now to notice, in the features which it presents, is even more startling still, and calculated to give no small shock to time-honoured prejudices. With its introduction ceases the ploughboy's occupation; and from the plough-tail we take him to the platform, and transform him into an engine-driver, working his machine on a veritable railway. Oh! shades of our broad-bottomed ancestors! what next?—and next? But let us explain: Imagine the field to be cultivated, to be laid out with a series of permanent ways, or rails, thus—



placed at a distance from each other of some thirty or fifty feet. At right angles to those rails (*a a*), along the headlands separate railways (*b b*) are placed. Imagine, further, two side-frames, each supported by eight wheels of small diameter, to run on two contiguous rails; these frames to be connected by a platform stretching over the intermediate space between the rails, and supported by the side-frames. This platform, in its turn, supports two steam-engines; one at each end. These give motion, by means of suitable gearing and connecting rods, to the small wheels on which the side-frames are supported. The two steam-engines are coupled together, so that one end of the platform, or one of the side-frames, shall not progress at a quicker rate than the other; by this means the uniform progression in the same line of motion of the platform along the rails is insured. To the under-side of the platform imagine a series of plough-bodies to be suspended, and to be adjusted so that, when moved along the space of ground between the rails, they shall cut furrow-slices of a determinate depth and breadth. Suppose the frame or platform, with its suspended ploughs—in number equal to a complete working of the soil the full allowable breadth

between the rails—to be near the headland, and on the near set of rails; the engines are set in operation; the wheels of the side-frames revolve, and the frame progresses up the field, at a rate determined on, until it reaches the opposite headland. The land between the rails over which the frame has traversed will thus be ploughed. The shifting of the frame or platform, with its suspended ploughs, to the next set of rails, is now to be performed. On the headland railway a low traversing frame—similar to that employed in railways for shifting carriages from one line to another—runs at such a level that the platform can be run off to a set of rails placed on it. The traversing-frame is then moved along the headland-railway to a point opposite the next set of rails on which the platform, with its ploughs, is required to run. By a very simple arrangement, the set of ploughs which were first in use are taken out of contact with the soil, and another set, working the contrary way, placed in order. The frame is now moved along the rails, and the ground between them ploughed as before. These operations are gone through till the spaces of ground between the whole sets of rails are all ploughed. One point in the arrangement of operations here performed will obviously strike the reader at this stage of our inquiry, namely, from the parallelism of the rails, and the ease with which, mechanically speaking, exactly similar adjustments of succeeding and diverse implements can be made to the platform, a degree of precision hitherto unattainable in actual culture can be insured. Thus, by the apparatus, the seed can be sown by means of the ordinary drill mechanism, and the spaces between the rising plants hoed by hoes or blades capable of most accurate adjustment to the frame. On this point the inventor states: "I have drilled by the steam-machinery rows of plants, and, when they have come up, I have hoed them repeatedly by the same steam-machine with the greatest perfection, and at all stages of their growth. In fact," he continues, "I have placed" (note that he states that he *has* done it, not that he *thinks* he *can* do it—a distinction worthy of attention here) "the blades of the hoes on each side of the rows, so near them as to cut within half an inch distance from the stalks without doing any injury to a single plant as the machine hoed them. I may mention," he goes on to say—and what he is about to say is worthy of saying, and of course of hearing—"that I have frequently placed upright in the ground two small sticks (two pencils) at a distance from each other of *one inch*, and, having fixed a small stirrer, or tine, propelled it at full speed of engine, cutting the ground between the sticks without on any one occasion disturbing either of them. So much for the *facts* proving the precision of the operation of the arrangements adopted by the inventor.

Another feature of the apparatus, which will be obvious to the reader, is that all poaching or padding of the soil—an evil inherent in all the methods of culture at present in ordinary use—is avoided; in fact, nothing comes in contact with the soil under culture but the implements and machines which are to effect that culture. But more of this important point hereafter.

Having now given a general notion of the peculiarities of the "Guideway Steam Agriculture," we proceed to enter more fully into details. In doing so, we shall divide our remarks into four classes: 1, Construction; 2, Practice; 3, Cost; and 4, Results cultural.

1. Construction. Under this head, the point which first claims our attention is the "permanent way." This may be constructed in one of two ways—first, by driving piles into the ground in the line of intended rails, these supporting a continuous top-rail, or beam, on which the rails are laid; or second—which is the method adopted in practice—by digging a trench on the line of rails, and forming a foundation, or ballast, after the manner of ordinary railways, and laying the rails on this. The rail used is not flat on its upper surface, like the ordinary rail of our railways, but angular in section; this gives a sufficiently strong yet cheaper rail than the ordinary one. The section being angular, the tires of the wheels of the moveable side-frames supporting the main platform have angular grooves, into which fits the apex of the angular rail. The rail does not rest on wooden sleepers laid on the ballast, but upon angular hollow bricks which act as the sleepers. The space taken up by the rails and the ballast is, obviously, so much taken off from the cultivable soil of the farm. This loss, however, is comparatively insignificant in amount, being calculated at 2s. per acre only. But, as the distance between each pair of rails is 30 feet—easily increasable to 50—the space of land lost by the rails and their ballast is much less than that in ordinary cases with the open furrows between the stetches. Mr. Halkett calculates that with a gauge of fifty feet, and a width of foundation for the rail of 2½ feet, 1-20th of the land is taken up by the rails. One set of driving-wheels, attached to one of the side-frames, have a lateral play or adjustment given to them on their axles; this arrangement meeting any deviation from the exact parallelism of the rails, or alteration of the width of the gauge, which may happen through various causes. This play or traverse of the one set of wheels is also useful in adjusting the implements which, in operation, succeed one another. Thus the drill-spouts or seed-depositors being made to travel at a regulated distance from the rails, the succeeding implements, the hoes, can be adjusted so as to travel in lines exactly parallel with the lines of motion of the drills, and, consequently, between the rows of growing crops. As no transverse ties or sleepers can be used, as in ordinary railways, to preserve the width of "gauge," this has been considered by some as militating against the utility of the system; it being argued that one of the practical difficulties in the maintenance of the permanent way of railways is keeping intact the width of gauge. But it should be remembered, on the other hand, that there is a vast difference between the speed of the railway locomotive and that of the travelling platform of Mr. Halkett, that of the former being up to as high a velocity as 50 and 60 miles per hour, while that of the latter is only about 2½ miles per hour. The succession of impacts given to the rail by the passage of a train at a high speed over them tends rapidly to destroy the integrity of the railway. In Mr. Halkett's system no inconvenience has arisen in practice from the want of any method to preserve the gauge of the rails. In view of the cultivation of the soil being carried on quite up to the line of ballast which supports the rails, it has been objected that the ballast will have a tendency to give way laterally, from want of solid earth on each side to support it. In answer to this, Mr. Halkett states that he does not cultivate close up to the rails to an equal depth with the rest of the space, but gradually slopes the cultivated part outwards from each side; thus leaving a considerable width of solid ground against the lower part of the ballast. Moreover, the slow rate of speed at which the platform travels is not found, in practice, to injure the ballasting. Even in cases where the soil may be ploughed quite up to the line of ballast, and to the ordinary depth, we do not anticipate that its lateral displacement will amount to much: besides, this lateral displacement can be easily obviated by simple contrivances. Again, it is to be remembered that the pressure of the whole apparatus is distributed over a large amount of surface by the use of numerous wheels—eight in number—on which each side-framing supporting the main platform rests; just as we find that a beam, which has the weight which it has to support distributed over the whole of its surface, can sustain a load double in amount of a beam which has its load placed on, or hanging from, the centre.

The main platform is constructed of timber framing, and in cross-section is exactly like a trussed roof, with the tie-beam, rafters, king post, or tie-rod, and struts, or braces. The tie beams or cross beams are not solid, but are made of two boards or planks placed on edge, and secured together by blocks or cross pieces; a horizontal board is placed at the lower part to resist the lateral strain to which the girders or beams are subjected. By this arrangement the necessary strength is ensured, with considerable lightness of material. We conceive that the hollow wrought-iron girder system could be adapted with success to the construction of a platform of wider space than any yet contemplated by Mr. Halkett. There is no engineering difficulty in the way to prevent a space of much above fifty feet being obtained. By the judicious use of wrought-iron a platform of great space, with all the rigidity required and of great lightness, could be constructed. But to return: The whole of the cross girders or tie beams are secured together by transverse bearers, which run in a direction parallel to the rails, and are further strengthened by light wrought-iron diagonal tie rods or stays, which stretch from corner to corner of the under side of the platform. The ends of the planks forming the sides of the girders or main tie-beams of the platform are secured to vertical uprights, which afford bearings for the running or driving wheels already alluded to. The bearings of these wheels are not fixed to those uprights, but are allowed to slide freely up and down in guides formed between the sides of the uprights; at the upper part of these guides strong springs, all of equal strength, are placed, to offer resistance to the bearing of the wheels when having a tendency to move too far upwards. By this arrangement the whole weight of the platform is transferred to these wheels through the medium of the springs. As before stated, these springs must be all of equal strength, so that each wheel may bear as nearly as possible the same amount of weight while resting on a level surface, and they must also possess a considerable amount of elasticity, to enable the several wheels to pass over any undulations of the rails without transferring too much weight from some of the wheels to the others. A maintenance of a uniform distribution of the whole weight of the platform on the wheels is what is aimed at in this arrangement.

At each end of the platform a steam-engine is placed: by preference the patentee employs the portable form, as engines of this class can be easily removed from one platform to another, and used for other purposes, as for thrashing, &c. The two engines are coupled together, the cranks of the main driving shafts being at right angles to each other; so that while one is at its dead points, the other shall be receiving the full impulse of the engine. The cranks are not on the same shaft, but are connected together by wheel gearing, and by a transverse or cross shaft, which stretches from one side of the platform to the other, and is supported on suitable bearings, bolted to the platform. To each end of this shaft a spur wheel is provided, gearing with a spur wheel of equal size, keyed on to the end of the crank shaft of the engine. The speed of the cross shaft is thus equal to that of the engine shaft. To reduce the speed of the cross shaft change wheels are used; the spur wheel on the cross shaft being thrown out of gear with the spur wheel on the crank shaft of the engine by means of a sliding clutch; another spur wheel on the cross shaft being at the same time thrown into gear with a pinion, or wheel of less diameter, fixed on the crank shaft of the steam-engine. The two engines are thus coupled together, and the motion of both so regulated that one side of the platform cannot advance quicker than the other.

To the outer extremities of the axles of the driving wheels, on which the platform rests, small cranks are keyed on, and which have a limited motion up and down, along with the bearings which have already been described. The crank pins of these cranks take into, or play in vertical slots, made in a horizontal, light, open framework, serving as a connecting-rod to connect all the cranks together. The extremities of these frameworks or connecting-rods are jointed to the crank pins of cranks, the shafts of which are supported in suitable bearings at the end of the timbers or planks of the platform. To the same crank pins the extremities of four connecting-rods—two at each end of the platform—are jointed; these are carried diagonally upwards, and jointed at their upper extremities to the crank pins of cranks which are keyed on at right angles to the ends of the cross shaft, which receives its motion from the engine in the manner already described.

Each wheel is thus made a driving-wheel, being acted on directly by the horizontal frame or connecting-rod, which receives its motion from the engine through the medium of the two connecting-rods, one at each end, jointed at their upper ends to the crank pins of the cranks on the cross shaft. The bite on the rails obtained by this arrangement is such that the engine can propel the platform up inclines of 1 in 15 with comparative ease, and without any momentum. Such is a brief outline of the peculiarities of construction of the mechanism of the new system—we now enter on the consideration of the second head, "practice."

And, first, as to ploughing. The method by which the ploughs are raised and lowered, that is, put in and taken of work according to the direction in which the main platform may be proceeding, is very simple. Each plough body is attached to the end of a long lever, the opposite end of which is jointed to the end of a bolt, firmly connected with the main platform. These points of suspension are capable of adjustment at any point of the platform. To the end of the lever, at which the plough body is attached, a curved guide is fixed; in the inner side of this bar, and towards its upper extremity several teeth are provided; the bar, in fact, forms a curved rack, the teeth of which enter into those of a small pinion, the axis of which revolves in bearings placed on the upper side of the main platform. As the rack is raised by the revolution of this pinion, the end of the lever, to which the lower or opposite end of the rack is fixed, is raised also, and with it the plough body, which it carries. A series of levers, with their racks, are placed parallel to one another, and to the rails on which the platform traverses. The levers bearing the corresponding set of ploughs, with their mould-boards pointing in an opposite direction to the mould-boards of the other set, are swung the opposite way; so that the curved racks of each set of plough levers are at opposite sides of the platform. When arranged for ploughing, one set of curved racks are depressed to their lowest point, the ploughs being in contact with the soil; the other set being raised to their highest elevation, the ploughs being suspended in the air. The pinions which gear into the segmental racks that raise or depress the plough bodies are keyed on to two shafts, which stretch across the full breadth of the platform, and revolve in suitable bearings. To the ends of the shafts cross handles are fixed, by means of which the attendants on the platform can work the pinions, raising or depressing the plough as required.

In ploughing by the implements as thus arranged and under control, Mr. Halket states that there is no practical limit to the depth of soil inverted. Neither, from the peculiar nature of the plough body used, is the hard crust or sole—inherent in the action of the ordinary plough—obtained. By his method of operation he succeeds in getting a stirred soil to the depth of twenty-five inches. On this point, he says: "I have first drawn six ploughs, cutting six furrows simultaneously

to a depth of five inches; passed over again to a further depth of five inches with the ploughs; and at fifteen inches below, in the subsoil of a hard yellow clay, drawn an anchor with a palm of nine inches width through the subsoil; thus ploughing and breaking up the ground to a depth of twenty-five inches." Although—as we understand—Mr. Halkett does not advocate the use of a rotary cultivator in the first instance, yet he has succeeded in obtaining some remarkable results in reducing obdurate clay to a state of amazingly fine tilth by using a rotary implement after the plough has broken up the land. The implement used resembles in character the well-known Norwegian harrow. Imagine this revolving in contact with the soil previously acted on by the plough; dashing the clods and lumps of clay against an inclined board, forming part of the casing in which rotary implements work, and which is dragged along by the main platform, which fall back again to receive the action of the revolving tines, till finally the couch and weeds are deposited apart, on one side, to be easily taken up and laid aside, to be burned, or otherwise disposed of; and the soil, in a state of fine tilth, deposited on the other. We saw, at the late meeting, the clay in its original condition, which gave apparently but little hope to any reducing system; and also its condition after it had been subjected to the action of the rotary cultivator, with the collection of couch which had been extracted from it; and certainly the results obtained were very satisfactory. All the implements and machines in use on a well-conducted farm can be worked by means of the platform with as much facility as the ploughs. Mr. Halkett has used, we believe, harrows, clod-crushers, hoes, drills, and has even reaped with the machine. Another novel feature in the system is what is called "underground watering:" this consists in "supplying to the roots of the crops, while at the same time the ground is stirred and hoed, water (or liquid manure), by drawing hollow bars between the rows of the plants, at the bottom of which the liquid escapes at any desired depth. By this means the fluid is economised on account of the evaporation from the surface being prevented; it does not cake the soil, which agriculturists object to as the result of the usual practice of watering, and it does not draw the roots to the surface in search of the moisture, afterwards to be injured by the parching of the ground."

We have now to consider, under the third division of our subject, the cost of the apparatus. The cost of putting the machine in operation on a farm would be about £20 per acre for the rails and £3 for the machinery; it is calculated, says Mr. Halket, to last as long as a horse, and may therefore be put down at 21 years' purchase. The following table shows the cost of the rails, and we may here state that Mr. Halkett is considered to have given a very liberal estimate of the cost of all the items, so that there is every probability of the cost per acre being reduced below that mentioned in the table.

Cost per acre of guideway upon burnt clay ballast, in which angle iron and angle tram bricks are used.

	£	s.	d.
800 feet of tram brick	£3	6	4
Laying down and providing ballast and levelling for tram bricks	3	10	0
Angle iron, 1½ lb. to the foot, and 14*l.* per ton ..	7	17	0
Bolts	0	12	0
Fitting fish joints	0	10	0
Fishing joints	0	10	0
Punching holes in iron	0	7	0
	£16	12	4
Contingencies at 10 per cent.	1	13	0
Cost per acre.....	£18	5	4

We now come to the consideration of the last division of our subject, the "results cultural," or as Mr. Halkett, at the meeting at the Freemasons' Tavern, on Thursday the 11th December, termed it, the "pith of the matter—the pounds, shillings, and pence part of the question." In proving the "large profits to be derived by this system of cultivation," Mr. Halkett, at the meeting already referred to, stated that he based his calculation on the following principles:—

"Spade labour is often used to cultivate the same crops as those farmed by horses. Spade labour is far more costly than horse farming; and being more costly, it must also be richer in produce. That it is so is universally admitted to be true, and, I may also add, with the same amount of manure in both cases. Now my system of cultivation is performed, at a cost including the interest for capital to pay for the rails, and depreciation and wear and tear, together with all charges for labour, while the work performed is equal in amount and depth of tillage to common farming, at a smaller annual charge than is now done by horses; while, if I increase the depth of ploughing, and the number of hoeings, stirrings, &c., so that the cost of my system is raised to that of common farming, while the work done is equal to spade cultivation, then all that is produced in extra crops is pure gain to a very considerable amount. If I take the usual computations of horse field-work, I find that the average is from £2 in country districts to £3 near towns: and if I take spade labour I find that it varies from £5 to £6., in fact to £3 per acre above the cost of horse farming, but the produce is at least worth £4 per acre more."

In corroboration of these views Mr. Halkett gives the following table from "Morton's Cyclopædia of Agriculture."

Table in article "Capital."

Acres.	Rent and Taxes.	Labour per acre.	Gross produce per acre.	Remarks.
	s.	£ s. d.	£ s. d.	Rotation—
240	40	2 0 0	7 18 0	Wheat, car-
20 spade husbandry .	40	5 10 0	12 7 0	rots, or potatoes, green crops for cattle.
Difference		3 10 0	4 9 0	

Other tables and evidence are given by Mr. Halket, which space does not allow us here to insert; but all corroborative of this, that the cost of spade husbandry per acre may be set down at between £5 and £6.

In proof of the assertion that by his system he can plough hard land at 1s. 7d. per acre, and light soil at 1s. 3d., Mr. Halkett gives the following tables:—

STEAM-PLOUGHING AND HORSE-PLOUGHING

Compared theoretically, ploughing in both cases at the rate of an acre and one-fifth per hour.

STEAM-PLOUGHING.

40 horse-power
× 8 lbs. of coal per hour

320
× 8 hours

	s.	d.
2560 lbs., or 23 cwt., at 1s. per cwt.	23	0
Oil, &c.	2	
Men { 1	5	0
{ 1	3	0
	33	0

33s. for 8 hours and for 24 acres = 1s. 5d. per acre.
Or 44s. 6d. for 12 hours and for 36 acres = 1s. 3d. per acre.

PLOUGHING BY HORSES.

40 horses, the day's keep at 3s.	120s.
20 men, at 2s.	40s.
	160s.

160s. for 8 hours and for 24 acres = 6s. 8d. per acre.

COST OF PLOUGHING BY ACTUAL TEST.
Furrows 5 inches by 10 inches.

Engines.	Steam per inch.	Revolutions.	Platform Travelling.	Drawing
Garrett's 6 h. p.	50 lbs.	110	2280 feet	Ploughs.
Barrett & Exall's 4 h. p.	48 lbs.	110	per hour	12

This was upon hard ground trodden on by the workmen for a year, and equals 5.7 acres per 12 hours, from which subtract one-tenth for shifting at headlands, gives 5.2 acres per day. Then 5.2 acres (amount ploughed by 10 horse-power) × 4 = 20.8 acres (say 21 acres) for a 40-horse power locomotive platform. Therefore 33s. (the cost of eight hours' ploughing by steam as shown above) divided by 21 acres, is equal to 1s. 7d. per acre, the cost of ploughing. Upon ground that has been ploughed some period before, but which had been trodden and rammed down, I have drawn 12 ploughs at the same speed, with a pressure of 32 lbs. in the 6-horse power, and 35 lbs. in the 4-horse power. This makes the ploughing much less than in the hard-ground example: it makes it 1s. 3d. per acre; or the amount could be increased per day of ploughing. The statement, therefore, of cost, at 1s. 7d. per acre, and 24 acres per day, may be considered a fair average.

It will be perceived that Mr. Halkett estimates the cost of coals at 20s. per ton; but it is well known that in many districts this estimate will be too high. In Lincolnshire coal is obtained for engine-purposes at a cost far, very far below this. It certainly cannot be objected to Mr. Halkett's estimates that they are too low; he in fact scarcely gives his own invention fair-play in this respect.

The following is a statement of the cost of operation per acre for a farm of 1,000 acres:—

	s.	d.
Ploughing 5 in. by 10 in.-furrows	1	7
Deep cultivation to the depth of 25 inches	12	0
Scarifying, grubbing, &c.	0	8
Harrowing, clod-crushing, rolling	0	5
Hoeing (150 acres could be done per day)	0	3
Drilling or dibbling seed	0	5
Reaping (cutting and delivering) at 60 acres per day .	0	8
Underground watering crops, at the rate of 3,000 gallons per acre, and 60 acres per day or night, or double this quantity if done by night and day ..	1	0
Surface-watering (with hoes following)	1	2
Carriage of manures on to and distributed over land, and of crops carried off, also carriage of marl, clay, sand, &c., 0½d. per ton per mile.		
The amount that can be carted at a time, for either water or manures, &c, 70 tons.		

With reference to the important point of carting-off the produce of the farm, Mr. Mechi, who took the chair at the meeting we have alluded to, spoke as follows:—

"To-day I went to the Polytechnic Institution, and heard Mr. Pepper lecture on this very subject. There were two trucks, each of which contained a ton-and-a-half of mangel-wurzel; and I saw two men move the three tons with perfect ease; and they would have had no trouble in passing from one end of London to the other, provided the roads were level. Now, I have had carted off many hundred tons of mangel-wurzel within the last month, and I find that on a clay-farm, late in October, two horses could only carry off at a rate which would require twelve horses to carry off eight tons; and the reason of that was nothing else than the difference in friction."

It is evident that this system of cultivation will work under most advantageous circumstances, where large tracts of lands can be obtained to operate upon. The question of the cost of its adoption—as much, as Mr. Mechi remarks, as the fee-simple of the land—is not the one which is surrounded with difficulties. It is not What does a thing cost? but, What per-centage will it pay? that is the question, the importance of which no one knows better than our manufacturers, who have certainly done more in the way of putting down costly mechanism than any other class. They stand alone in this respect. The real difficulty in the way of a wide extension of this system, is getting large farms to operate upon—apart, of course, from all questions of mechanical and cultural fitness. Mr. C. W. Hoskyns, at the meeting to which we have already so frequently alluded, pointedly drew attention to this. In stating that Mr. Halkett would have great impediments to encounter in carrying out his system, he remarked that one of these would arise "from the difficulties which clog the advance of any agricultural system on a gigantic scale, where large tracts of land are necessary to be purchased. The laws of settlement and entail offer great objections, and also the enormous expense and delay in transferring land. The first objection that occurred to me was the difficulty that awaited him in getting farms on such a scale as to be able to realize his mode of cultivation, supposing he had mastered all mechanical and engineering difficulties."

But our lessening space reminds us that we must draw our paper to a conclusion as rapidly as possible; we therefore hasten to offer an abstract of the advantages obtained by this system of cultivation, as stated by the inventor:

1. The whole weight employed in culture being taken off the land, the operations can be carried on in all weathers, and in any condition of the soil.

2. The land is left in a state of lightness not attainable where more horses and implements press upon while it cultivating.

3. Consecutive ploughing in exactly the same lines being easily obtainable, a greater depth of soil stirred than is usually arrived at can be insured.

4. The bringing up of fresh soil for intermixture with the top-soil in any desired proportion.

5. Facilities for carrying on manure, and depositing it on the land.

6. Facilities also for carting off produce.

7. Also for carrying soil of different qualities to intermix with the soil of the farm.

8. Precision of operation [this we have already enlarged upon].

9. The operation can be carried on by night and day.

Whatever may be the opinions of some as to the soundness of these presumed or stated advantages, it certainly is the case that many are disposed to look upon this system of Mr. Halkett's as a move in the right, the philosophical direction. It is fast becoming an established opinion amongst engineers and mechanicians, that before the full advantage of the application of steam-power to the purposes of cultivation can be obtained, there must be an adaptation of the land to the peculiar features of the new power to be employed. If local or other peculiarities prevent the free and economical action of the power of steam, those peculiarities must be got rid of before full satisfaction can be obtained. And in the long run it will be found a cheaper method to get rid of, for once and all, those peculiarities which prevent the free action of the machine, than to adapt self-adjusting or other arrangements to the mechanism, by which it can be enabled to stop itself, till the peculiarities which impede its free action are got out of the way. Thus we can conceive of a plough being dragged by the steady power of steam across a field, and which has a self-adjusting mechanism given to it, by which it either stops its own progress if coming in contact with a boulder, or else is enabled to slide over it without damage. But the philosophical, and in the long run the cheapest, method of procedure, is to get rid of the stone altogether. Root it out: take it away: it is only an obstacle, and an ever-recurring one if allowed to remain. Our cotton manufacturers know the value

of this method of working: it is one of the secrets of their success. They grudge no outlay in mechanism and processes to perfect the material for the action of the higher and finishing class of machines. Why should not our agriculturists do the same thing, if they are anxious, as we know they are, to avail themselves of a power which is most undoubtedly capable of untiringly and economically doing the work, or a large proportion of it at least, of our farms? The whole question is one of cost only, not of mechanical or cultural difficulty. If eminent machinists say that with properly-adapted land they can and will construct machines which shall do the utmost amount of work, and that far beyond the realized produce of the present system, then the first thing clearly which the farmer has to do, is to begin this work of adaptation, that is if he thinks it worth the cost. A calm view of the whole circumstances of the case tends to show that nothing perhaps has prevented the adaptation to farm purposes of high-class machines, worked by steam-power, so much as the obstacles thrown in the way by the peculiar features of the land on which these machines have to operate. We do not ignore the fact that the soils possess features infinitely more crude, unequal, and varying than the materials on which high-class manufacturing mechanism has to operate; but there is little doubt that these peculiarities can be greatly obviated in many instances, and totally removed in others. When many of our engineers—the gifted William Fairbairn at their head—hold opinions such as those we have endeavoured to state, the time is near at hand when our agriculturists will see, with them, the necessity of "beginning at the beginning." It should always be remembered that the adaptation of a new power involves new circumstances of action. The finest locomotive that ever a Stephenson or a Hawthorne made, could creep but quietly on our best-paved road; but give it the iron rail, and lo! the lightning speed.

It is just when viewed in this way that the system of steam-cultivation invented by Mr. Halkett presents considerable promise; so much so, that it is deserving of the most searching inquiry by all those interested in the progress of agriculture. It is just because that, in using a new power, Mr. Halkett has carried out a new method of preparing his land, and that too a method which experience shows clearly enough—the experience of our railways—is well adapted to the new power. In this mutual adaptation of the power and the land lies the secret of the *complete novelty* of the system in an agricultural point of view; and is that, moreover, which presents a species of fitness and unity which goes somewhat towards satisfying the mechanical requirements of the case.

As to the way in which it satisfies, or is likely to satisfy, the agricultural requirements, we cannot do better than quote Mr. Hoskyns's remarks on the system. We can bring forward no better authority:

"Any gentleman unacquainted with the extraordinary difficulties of a clay soil, cannot have the least idea of the benefits to be derived from this mode of cultivation, which will perform the process of culture without having the animals poaching, as we call it, the ground; that is, treading and leaving the marks of 16 iron-shod feet on the soil as the fulcrum of power on the land. As far, therefore, as it is possible to look at Mr. Halket's plan generally, it appears to me that two great advantages are gained by it. The first is the immense saving of power by means of the rail. I do not here enter into any question of deflection that may be supposed to exist, as that is only a question of detail, which by no means should stand in the way of ultimate success. The first great advantage, I say, is the immense gain of having an iron track to go upon, instead of the moist and sticky earth. Here he has always a clean road, and one on which I can see the greatest amount of power is to be obtained at the least expense. The second advantage is to be able to cultivate clay soil without any weight whatever attached to the machine that cultivates or the power that draws the machine; that is to say, that if it is for ploughing, the plough is to go through the ground without any pressure on the soil. In the act of lifting there is a degree of pressure by the tugging irregular action of the horses, because we all know that the tug is very unequal. With mechanical action, even when applied to ploughing, we know that the results are far better; but I say that nothing can be worse than the action of a plough with four horses working on the land, as we see every day in winter. The question, therefore, is the successful solution of the problem of the cultivation of clay soils without having any horses or heavy machines pressing into the soil during cultivation. When we have accomplished that, we shall have done more to advance the value of the clay soils of this country than is done for light soils by the introduction of machinery. Clay soil is more valuable, as it contains a far greater quantity of food of plants in a form more difficult to be taken away either by moisture or the heat of the sun. Then we shall be able to make twelve months' soils, instead of what the farmers call six month's soils."

In offering our own remarks on this invention, we deem it right to state that they are not given in the spirit of the partizan—they are thoroughly independent of all circumstances save those connected with the mechanical and cultural features of the invention. It is alone with these features we have to do—any other are completely and altogether indifferent to us. It is our earnest desire to give a fair field to all, and to see all inventions considered with candour and fairness, their good things cordially acknowledged, their faults generously pointed out, remembering always the pregnant words of Bacon, "As the birth of living creatures at first are ill-shapen, so are all innovations which are the birth of time." He were a poor soul indeed who contemned the child because it possessed not the features nor displayed the vigour of the man. How often as wise a thing is done, in judging of the merits of an innovation, let the records of the experience of our poor patient inventors tell.

R. S. B.

ANNUAL REPORT OF THE LINSEED AND OILCAKE TRADE.

SIR,—We have again the pleasure to furnish you with our annual circular, and can but regret that the forebodings expressed at the beginning of the year just passed should have been realized even to a much greater extent than we could then have considered possible. The general inflation of trade, however, was not without its effect on the articles in which we are interested, and the speculations of the spring and commercial collapse of the autumn will render the history of the year 1857 a most memorable one, and in no trades more so than in seed crushing. From the time of the publication of our last circular until now, the trade was never less remunerative, but it is to be hoped the lower range of prices now current will place it in a healthier condition, and render business, both to importer and crusher, more profitable than of late. The last three months must have shown how inherently sound the trade was, and we trust that the caution exhibited by the crushers previous to, and during the present crisis, will carry them through the season at a less loss than might have been feared from the panic occurring just at a time when, of all others, they were likely to have been overtaken with heavy stocks.

We have again returned to Black Sea seed as the standard of prices, the import of that description being again greatly in excess of all other sorts.

Linseed was worth 63s. in January last, and the expected short supply gave the market an upward tendency, and it was daily in holders' favour, so that before the end of that month 66s. was currently paid for parcels on the spot; and an advance of 1s. to 2s. per qr. obtained for cargoes on the way. February marked the highest prices of the year, 70s. 6d. having been paid for Odessa, and as high as 73s. for Bombay. At this period also some of the importers took advantage of the buoyant state of the market on the spot, to place seed for summer shipment, and several speculative purchases for shipment during the season, from the Azov, were made at 64s. to 65s. In March, notwithstanding stocks were very light, the feeling was strong that prices were too high, and purchases were made on the smallest possible scale, so that the price on the spot again fell to 66s.; and in April a further decline of 3s. per qr. was realized. In May, stocks had become so reduced a recovery to 65s. took place, and some further very considerable sales were made of seed for shipment at about same price. Early in June we were flat at 64s., but at the end of the month had again improved to 66s., although the high price rendered business very difficult, crushers fearing to accumulate stocks at such unusually high rates. During this month, also, a circumstance occurred, which exercised a marked influence on the prospective bearings of the trade. We have named that, during the course of the previous four months, a large quantity of seed had been sold (chiefly to speculators) for summer shipment, from the Azov; and at about this time, the prevailing drought in the south of Russia rendered it probable that the greater portion of it would be detained until another season, owing to want of water to float the loaded barks down the rivers to the various shipping ports. The leading sellers, therefore, quietly covered in their contracts; and the fact afterwards being made public, crushers also became anxious as to their future supplies, and bought freely of such descriptions as offered the greatest inducement to purchase. It turned out, after all, that means were found to convey the seed overland, and merchants and crushers were alike caught at high prices, and, eventually, heavy losses entailed, which would not have happened but for this accidental occurrence. In July, the market was steady, at about 66s., with stocks in the smallest possible compass, and, but for the unlooked-for import of oil from Hamburg (causing the closing of the mills in the face of so heavy a loss in working), we should probably have had a much higher range of quotations on the spot, and, in anticipation of the then expected short supplies, for shipment also. In August, some of the early speculative purchases arrived at Falmouth, and, not finding a ready market, prices receded to 64s.; but the decline was recovered by the end of the month again. During September, 66s. remained a current price, and the prospects of both oil and cake being encouraging, some further speculative forward purchases were made as high as 67s. and 68s. In October, the pressure for money began to tell, and, notwithstanding the unprecedented support given to the market by holders warehousing nearly every cargo that came to hand, the downward movement could not be checked, and 63s. was an outside figure before the month closed. The incidents of the last two months must be so painfully fresh in the recollection of us all, that we need scarcely recapitulate them. 60s. was November's earliest quotation, and a decline of about 2s. per week followed, the market leaving off very dull at 52s. Last month a further fall occurred to 49s. to 48s., and the unexpectedly heavy arrivals from all quarters (including several reshipments of East India seed from the United States), combined with the want of facilities in money matters, would probably have caused a greater decline, but that holders, finding the utter impossibility of selling, resigned themselves to the force of circumstances, and an unusual quantity therefore has been housed to await a better demand. This has shown itself the last two or three days, and the tone of the market is stronger, 50s. being now the nearest value.

The crushing trade has been uniformly bad throughout the year—prices having been kept up beyond their natural level by continual speculative operations, and the demand for oil and cake not keeping pace with these, the result to the crusher must contrast very unfavourably with the past three or four years. We hope, however, we have less discouraging prospects for remainder of the season than at same period last year, for we have ample stocks afloat, and in granary. We may likewise expect full supplies from the East Indies; the late utter prostration of American credit probably causing (for a time) a stoppage of all shipments thence; besides the United States sparing us some of the large quantity they have still on the way and in stock, and which owing to their present monetary derangements, they are prevented using.

As regards the season 1858-1859 it is quite impossible to form an opinion before we are out of the present crisis; our panic cannot be without its effect on the producing countries, and we think we may reasonably look for a low range of prices for some time to come. The Baltic seed is highly spoken of as to quality, and fair in quantity. Archangel is not so well harvested this season. The crop in the south of Russia is reported short; it generally is, and little dependance can be placed on the reports thence. We presume the means of information must be very scanty, for we were led to believe the last year's crop would be under 200,000 qrs., whereas it has turned out over 500,000 qrs. From Bombay we may again look for an increased quantity; but the aggregate shipments from Calcutta will probably be short of last season, owing to the unhappy disturbances existing in the surrounding districts. At the same time, however, we shall have a much greater supply sent to this market than at the corresponding periods of the last two years, owing to the temporary cessation of the business relations between the East Indies and America.

The quality of the Black Sea seed has been most unsatisfactory in the Azov districts, apparently from a bad harvesting season originally, and subsequently owing to a large portion of it having been transferred from the barks and conveyed overland to its port of shipment, thereby exposing it to the risks of weather, &c. Some of the Odessa shipments really did not deserve the name of Linseed; but the disgraceful practice of admixture has at length reached such a pitch as must inevitably put a stop to it altogether, and the late combination amongst the crushers to alter the existing "usual conditions," on forward contracts, will (if energetically followed up and acted upon) in future put the trade on a more satisfactory footing in this respect. Archangel and all the Baltic seeds have unlike been unsatisfactory; they were both ill-grown and badly harvested: the late war had probably a good deal to do in bringing about this result, and its recurrence from such a cause is never likely, we hope, to happen again. Bombay seed was hardly so good as in former seasons. The very small quantity of Calcutta which came to the United Kingdom was again rather better than that of the previous two or three years' import.

In presenting you with the usual statistical account of imports and stocks, we cannot help remarking how widely different they prove to most of the calculations entered upon during the summer. We were told the total import was to be less than 800,000 qrs., and that by this time linseed would be nearly exhausted; whereas we find, on reference to our previous circulars, that the quantities warehoused, and known to be on the way, are more than double those of any previous season; that is to say, more by about 200,000 qrs.

In public warehouses here the stock amounts to 88,000 qrs., namely, 42,000 Black Sea, 24,000 East India, 11,500 Petersburg, 5,000 Archangel, and 5,500 sundries. At Hull there is 190,000 qrs., and at Liverpool 30,000 qrs. Afloat we have 230,000 qrs.; say 150,000 Black Sea and Azov, 50,000 Calcutta, 10,000 Bombay, and 15,000 Alexandria, Danube, New York, and sundries.

The import into London is again short of the two previous years. The aggregate into the United Kingdom will not be so great as 1856, but it will probably be in excess of any other previous year. The official returns of the several years have been as under:—

1841	363,461 qrs.	1850	603,984 qrs.
1842	367,700	1851	630,471
1843	470,539	1852	799,402
1844	616,947	1853	1,035,335
1845	656,793	1854	828,513
1846	506,141	1855	756,950
1847	439,512	1856	1,180,179
1848	799,650	1857	about 1,050,000
1849	626,495		

The imports of the working season, that is to say, 1st July to 30th June, were as follows, namely:

1848 to 1852	..	..	..	700,000 qrs.
1849 „ 1850	..	..	..	600,000 „
1852 „ 1853	..	..	..	825,000 „
1853 „ 1854	..	..	..	1,030,000 „
1854 „ 1855	..	..	..	1,006,000 „
1855 „ 1856	..	..	..	644,000 „
1856 „ 1857	..	..	..	1,092,047 „

1857 „ 1858 will probably be rather in excess of that quantity.

60,000 qrs. Bombay, 40,000 Calcutta, 80,000 Black Sea and Mediterranean, 20,000 Baltic, 10,000 Archangel, 5,000 Alexandria, 13,000 American transhipments and sundries, were the quantities reported at the London Custom House. The re-export was again light, and consisted of about 30,000 qrs., against 45,000 qrs. in 1856, and 130,000 qrs. in 1855.

The total supplies into United Kingdom again exhibit a curious alteration in the description of Seed imported; the great falling-off has been from Calcutta, viz, this year only 90,000 qrs, against 225,000 qrs. in 1856. This, however, was more than counterbalanced by an excess of 185,000 qrs. from the Black Sea, comparing the same periods. Bombay supplied 120,000 qrs., St. Petersburg sent us 190,000, Archangel 60,000, Riga 75,000, and Memel and other places in the Baltic about 80,000, and Alexandria and sundries 60,000 qrs. The Black Sea cargoes amounted to 377,000 qrs.; and were discharged at the undermentioned ports: Hull 130,000 qrs., London 70,000, Grimsby 25,000, Liverpool 12,000, Southampton, Ipswich, Dover, and Newcastle 10,000 each, Ireland 5,000, Leith and Lowestoft 4,500 each, Yarmouth 3,500, Boston 3,000, Rochester 2,000, Gloucester 1,700, and Lynn 1,200. At Antwerp 55,000 qrs. In Holland 18,000 qrs., and at Dunkirk 1,500 qrs.

The various continental ports were also furnished with about 160,000 qrs. from Archangel, St. Petersburg, Riga, Memel, and other Baltic ports; St. Petersburg supplying 40,000 qrs., Archangel 55,000, and Riga 35,000 of that quantity. From Riga, also, 75,000 qrs. of sowing Seed were shipped; nearly half to Ireland, and remainder to Germany, France, &c.

LINSEED OIL has fluctuated much less than usual during the past twelve months; about £40 appearing to have been the turning point previous to the late collapse of all prices, caused by the existing state of general trade and high rates for money. In January the price opened at £37 10s., and the prospects of the supply of seed being very discouraging, crushers were most reluctant sellers, and held so firmly, it had advanced to £40 15s. by the end of that month. In February the speculators came in, and drove it up to £42 10s. on the spot, and £43 for summer deliveries; but the rise was too fast, and a reaction set in, so that before the month closed, the advance had been lost, and by the end of March it had declined to £39, with a very dull market. During April it receded to £38, at which price considerable quantities were taken for the French markets, and the value again quickly rallied to £40. In May it touched £42, thereby bringing out numerous sellers, and £40 was again the quotation at the end of the month. In June it was remarkably steady at same figure. July deserves special notice, for it was in this month that large sales (for delivery by end of September, and at first considered to be purely speculative) were made on Hamburg account, and the market consequently rendered very sensitive and unsettled. The price at which these sales were made was about £39 10s., and it afterwards occurred that several hundreds of tons of English-made Oil, which had been lying at Hamburg during the previous eight or ten months, were re-imported to supply the contracts so made. Our stocks, however, at this time were so light, the import was quickly absorbed, and, although the price was once quoted as low as £38, it had again recovered in August to £40.

We may here remark that the extraordinary export from Hull of the previous year is now accounted for, but the loss attendant on such a speculation will, we should think, effectually bar its reputation. If, also, the general style of business at Hamburg has assimilated to the reckless mode of trading shown by some of the operations in oil, we need not wonder that the late sad commercial disasters have been more severely felt there than in any city in the world.

In September there was a large and steady trade at a fraction below £40. In October it felt the effect of the money pressure, and with a wretchedly dull market had declined to £35 before the month closed. November was to have been the charmed month for the speculative account, and it had been calculated the options open, and the over-sold account together would enable the "Bulls" to force settlements at their own figures, first taking delivery of all the actual oil that could possibly have been tendered. An abortive attempt was made early in the month to run up the price, and £36 was quoted, but it was soon found the times were too difficult for such an operation, and oil proving much more plentiful than cash, a sudden drop to £32 occurred, and before the month closed a further fall to £28. In December holders continued to realise, and £27 10s. was accepted, but its present relatively low value to all other oils has attracted some attention, and we have the last few days had a good trade doing at £28 10s. to £29, with buyers for future monthly deliveries at an advance of £20. per ton.

The exportation, for the reasons just named, shows a very serious falling off. It amounts to about 16,000 tons only, against 28,000 in 1856, and 17,500 in 1855.

LINSEED CAKES were in active demand during the spring at about £10 10s. per ton, and after being dull during the summer at something below that value, recovered as the autumn progressed, with every prospect of a further advance. Notwithstanding also the late general collapse of prices for all other articles, they still about maintained their quotations, and the last few days they have been in increased demand at £10. We never before had so steady a trade or so few fluctuations as in 1856.

The import of FOREIGN CAKE has been unusually large, say probably 10,000 tons, or nearly 20,000 tons in excess of 1856 and 1855. The trade in January was quite of a retail character, the quotations being, for New York barrels £11, bags £10 5s., and square Marseilles £9 5s. C. F. and I. Early in February the market showed symptoms of improvement, and a fair trade was done at an advance of 5s. per ton on all descriptions; but it was not maintained, as very heavy arrivals of Marseilles frightened the dealers, and prices continued declining all through March. Importers' continued anxiety to realize dropped the value fully 25s. per ton by the end of that month, and early in April the lowest point was touched, say £9 7s. 6d. for barrels, and £9 bags. The great fall naturally attracted the attention of dealers, who made heavy purchases, but any advance was checked by the large supplies which daily came forward. The demand continued throughout May, and sellers showing less disposition to realize, obtained an advance of 10s. per ton. The consumption was great all through June, and very soon a further improvement was established, and by the end of that month an additional 20s. per ton obtained, the quotations being £11 for barrels, £10 10s. bags. During July we had no alteration in prices, and a steady trade was done; but there was a drop of 10s. per ton in August, in consequence of the slack demand. In September and October some anxiety was shown to provide for future wants, and prices rallied again, closing firm at £11 for barrels, £10 10s. bags. During November and December we have declined 10s. to 15s. per ton, and in consequence of the fine open weather all through these months, we have had but a slow sale, and our quotations to-day are £10 10s. for barrels, £10 for bags; square Marseilles about £9 C. F. and I.

RAPESEED AND OTHER OILSEEDS.—The imports are about one-fifth less; say 200,000 qrs., against 264,919 qrs. in 1856, but the re-export not exceeding about 65,000 qrs., whereas in 1856 it was 150,000, it follows the quantity left for home consumption has been somewhat in excess of the previous year.

RAPESEED during the first three or four months was in request, and an advance took place from 63s. to 70s.; fine Bombay realising as high as 76s.; it afterwards declined to about 65s. in May, and has almost been a dead letter since, so little business having transpired. Prices are now nominally 53s., but the article is of most difficult sale. In warehouse, of all descriptions, we have about 45,000 qrs., and afloat 10,000 qrs., against 65,000 qrs. in granary and afloat last year.

The following are the quotations for other Oil Seeds, but they are at present quite nominal: Poppy, Sessame, Teel, Sursee, and Gingelly, 52s.; Niger, 45s.

RAPE OIL this year requires nothing more than a register of prices. English refined scarcely varied during the first nine months of the year, and was quoted 52s. to 54s. during all

that period, and only since the commencement of the panic has it retrograded in value. In October the price was 50s.; in November 43s. to 43s., since which it has recovered to 45s., and is steady thereat. The official imports, as at present given, combining all Seed Oils, we cannot give the comparison this year, but the aggregate makes it appear to have been double that of 1856. The home make has also been larger than usual, crushers having found it pay better to work than Linseed.

RAPE CAKES has been in varying demand throughout the year, at about £5 10s. per ton for English, and £6 10s. for best Foreign makes.

FISH OILS held their values very steadily, and without great fluctuations, until October, when they sympathised with the state of the money market, and we have since had to quote much lower prices. SPERM OIL was £88 in January, rose to £100 in March, and afterwards fluctuated at about £90 until October, and is now only about £67. SOUTHERN stood at £46 to £50 during the earlier months of the year, and its nominal value to day is £42. PALE SEAL is quoted £39, whilst, during the first six months of 1856, it was firm at £49. COD OIL, however, has experienced the greatest decline, having within the last four months receded from £49 (at about which it stood for many months previously) to £29.

TALLOW.—During the first six months of 1857 the market for P. Y. C. was the scene of one continued struggle between Bears and Bulls, ending in the former being severely punished, and we fear without a very profitable result to the latter: 58s. was January's value; 68s. February's; early in March it was supposed the speculation had again this year broken down, and a few venturesome sellers placed some at 62s., but were caught, and had to settle at 80s. at the end of the month. In April prices opened at 56s., but rapidly receded to 51s. 6d., and as quickly recovered to 59s.; May showed fluctuations between 55s. 6d. and 58s.; in June we had a repetition of the March account, for heavy Bear sales had also been made for April to June deliveries, in expectation that all the Tallow received and held over in March must come out for sale within that period, but sellers again "calculated without their host," and had to settle at 75s.

Since that period, although the speculative influences have been at work, we have not had the extraordinary fluctuations of the spring, and until the month of November, when in sympathy with every other article of commerce, Tallow experienced a great decline, the market was steadier than usual. In July about 58s. was the value; in August it ran up to 65s. It opened at 63s. in September, closing at 58s. 6d. In October it began to give way, and left off at 56s., declining rapidly to 47s. in November. It has since recovered to 53s., and is very steady to-day at this price.

London, Jan. 1. EDWARD EASTTY & CO.

ANNUAL REPORT OF THE LIVERPOOL WOOL TRADE.

GENERAL REMARKS.—In our last annual review of the wool trade we expressed favourable views of the future. The state of business at that time was, in the highest degree, satisfactory, and held out promise of a continuance of the prosperity we had some time happily enjoyed; nor have these anticipations been altogether disappointed, since, notwithstanding occasional complaints of some branches of the trade being unprofitable, consumption during the greater part of the year continued on a scale of unwonted activity, which was sufficient to cause some uneasiness as to how this was to be met later on in the season. Notwithstanding the excitement which prevailed at one time on the subject of a short supply of cotton, it is doubtful whether there was not really more cause of alarm in the case of wool, which, under the most favourable circumstances, is susceptible of comparatively slow increase, and is besides liable to more than an average amount of casualties. We have referred to this on previous occasions, but general opinion has not altogether viewed it in the same light, and is least of all likely to do so in the present altered state of affairs. The argument of the Yorkshiremen has been that they have never yet met with actual scarcity, and, as long as there was money to purchase, they had no fear of any inconvenience. It is, however, an established fact that for several years past, in the spring there has been considerable excitement in the market, owing to the insufficiency of stock, and prices have for the time been considerably enhanced in consequence. It is well known that the consumption of wool has greatly increased in every quarter, and everybody who has the means of judging must also be aware, that the growth has not kept pace with it. The manner in which prices have been supported, and the fact that during a period of such unexampled pressure, a quantity of the value of one million sterling could be disposed of at the ate public sales at such satisfactory prices, at all events add ome weight to these arguments. With some slight intermission, trade continued good until October, and, although for some time previously a note of warning had been sounded from the United States, it failed to exercise much influence on this side; but early in this month the accounts became still more alarming, which induced the Bank of England to raise the rate of discount on the 8th October from 5½ to 6 per cent., rapidly followed by further advances during the same month to 8 per cent., which was again increased within the next fourteen days until on the 9th November the *minimum* rate had attained the unheard of point in this country of 10 per cent.! These stringent measures altogether failed to check the efflux of gold, and at length the position of the Bank of England itself became so critical that, on the 12th December, it was deemed imperative to suspend the Bank Charter Act. This gave some temporary relief; but the havoc caused in the meantime among the commercial classes had become too deeply rooted, and the feeling of mistrust had extended so widely that for a long time numerous failures continued to take place. Up to this time the panic had been chiefly confined to the United States and houses in this country, in France, Belgium, and Germany engaged in trade with that quarter; but it soon assumed greater dimensions, and became general throughout the whole continent of Europe, reacting again with great severity on this country. Produce for a long time continued almost unsaleable, even at very considerable sacrifice, and it may well be doubted whether any panic in our commercial history will bear comparison with the present, for intensity, protracted duration, and the extent of ruin it has caused. The number of suspensions has been truly appalling (estimated in this country alone at fifty millions sterling!) and while in many cases they have no doubt been the result of overtrading, fostered by indiscriminate Bank accommodation, still many old familiar firms have also had to succumb; it is to be hoped, however, that some of these will eventually be able to resume business. The Indian mutinies and the alarming state of affairs in that quarter have been a subject of engrossing and painful interest, and have tended in no slight degree to increase the gloom during the last few months; but happily the worst is now over, thanks to the ability and energy of our commanders and the valour and endurance of our troops; and it is to be hoped that our power will soon be completely re-established upon a firmer footing than ever, and that the railroads now in course of construction will greatly tend to consolidate and to develope the resources of that country. Notwithstanding the close of the year has been attended with so much to discourage, there is also great cause for thankfulness in the bountiful harvest with which Providence has blessed not only this country, but other countries also, and the very low prices of all necessaries of life will to some extent alleviate the condition of numbers of the labouring population who have been partially thrown out of employment.

HOME DEMAND FOR WOOLLEN GOODS.—There has perhaps never been a period when the population has been so fully employed, and at such high wages, as during the past year. Consumption of goods has, consequently, been unprecedentedly large; and, under all circumstances, we think there are reasonable grounds to hope this will continue to a fair extent.

EXPORT OF WOOLLEN GOODS.—The continued increase

in shipments for some years past has been very considerable; and, although in the previous year they had reached a very high point, we expressed an opinion in our last annual report, judging from the state of the markets abroad, that there was on reason to apprehend any falling off. This has been realized to the fullest extent; and, notwithstanding the decline during the latter months, chiefly to the United States, the exports for the past year will greatly exceed any former period; and we venture to predict that during the present year, to the United States, they will at least show no diminution.

CONSUMERS.—Even at the commencement of the year there was a strong disposition to resort to short time, chiefly by those who had missed the opportunity of supplying themselves while wools could be bought at anything like reasonable rates; but it was found the least evil of the two to work without profit, or even at a little loss, for a short time, till the new clip came to market. For some time after this, prices continued to advance; and those who purchased early must have done well, although parties holding large stocks at present (which, however, is quite exceptional) will have little cause for satisfaction. While the consumption has been very large, we believe, on the average, profits have been very small in the worsted districts; but those engaged in the clothing trade have occupied a much better position.

WOOL TRADE.—The home clip is computed to have been somewhat deficient in quantity, partly the consequence of increased demand for stock during the last two years, the improved position of the labouring population enabling them to expend more in animal food. The consumption of domestic wools has, at the same time, very materially increased in the worsted districts. Prices were firmly maintained in in the spring, particularly for bright-haired descriptions, which have throughout the year been much run upon. The defeat of Ministers on the 4th of March, on the Chinese question, rendering a dissolution of Parliament necessary, gave a check to business (Yorkshiremen taking a warm interest in politics), and, as clip time approached, prices became unsettled, buyers generally feeling indisposed to operate freely at the existing high rates. But as soon as the new wools came to market, great eagerness was evinced to stock themselves freely; and prices continued to advance, and probably at no time were wools more rapidly taken out of the growers' hands. The enlarged demand for home descriptions in the combing districts has been greatly to the exclusion of fine combing colonial, where formerly this description commanded the highest rates. It has nevertheless been in good demand for clothing purposes, the length of staple, combined with the healthiness of the wool, enabling them to mix up a large quantity of shoddy in the manufacture—a system which, owing to the high prices of wool, has been greatly on the increase. The reaction in business, which began early in October, took the trade altogether by surprise, even the most cautious; for up to that time the condition of the article was, on all hands, admitted to be as sound as could be desired. It is true prices were high, but this was clearly traceable to the large scale of consumption, which had existed up to that period, and if no interruption had taken place there cannot be a question that much higher rates would have been attained. There is scarcely an article that has maintained its position so well, or has been so exempt from failures during the late crisis. With the exception of the Public Sales in London, business has been at a complete stand for the last two months, and profitable inaction has been the rule, excepting an occasional forced sale either from alarm or to meet some pressing emergency. Some improvement has lately taken place, but prices must still be considered to a great extent nominal. The consumption, on the average, has been reduced to three or four days a week, but we think that our trade will be one of the first to feel the effects of returning confidence. The present position is widely different from the former panic in 1847, which was mainly the result of reckless overtrading and inordinate railway speculations. We had then also to contend with famine prices of all necessaries of life, whereas now they are correspondingly low—a very favourable feature in future prospects. At length we have been relieved from the 10 per cent. minimum Bank rate, which was reduced on the 24th ult. to 8 per cent., and there are indications that a much easier rate of money will ensue, and we think there is every reason to expect an early and general revival of trade.

WOOL IMPORTS.—Our receipts have greatly increased, having been 176,144 bales in the past year, against 134,346 bales in the preceding one, which may be taken as evidence of the central position and growing importance of this market. The late disastrous events all over the continent have greatly tended to divert shipments to this quarter, but we regret to observe that they have consisted to a large extent of uncurrent kinds, unsuited to our requirements, which are only saleable in brisk times, except at very low prices. It will be noticed that no less than 24,679 bales from the Australian colonies have reached this port, of which only a most insignificant portion was left here for sale; but this will create less surprise, when those interested in monopolizing the trade in London have freely stated that they will have them sent up there, even to be sold at lower prices than could be obtained here. Trade is of course at all times liable to vicissitudes, and it is well to place on record at least two occasions during the past year, when, if the wools had been retained here, the sales would have resulted in signal advantage to the importers. A great portion of the early arrivals from Port Philip was brought by the Liverpool clipper ships, of which part was sold here on arrival by private contract at 2½d. per lb. advance on the closing rate of the previous London public sales, and the whole might have been most advantageously disposed of here at the same time at auction, as the stocks were then quite exhausted and there was an eager demand. The next public sales in London, commencing in February, opened with a corresponding advance, which was well maintained for a short time, till the defeat of Government at once caused a reaction, the whole advance was soon lost, and up to the close the sales proceeded with very great heaviness. In confirmation of this, we may state that for some of these wools we ourselves made offers on arrival which were refused, and they were subsequently sold for 3d. per lb. less. The second case to refer to is the public sales held here September 30th, when 1,000 bales Port Philip met with a brisk competition at very satisfactory prices, fully maintaining the highest rates current at the previous London sales in July and August, but as we stated at the time, if the quantity had been of more importance, we have no doubt the result would have been more favourable. The subsequent public sales, in London, showed a decline from our prices of this description of *at least* 2d. per lb., but in most cases even 3d. to 4d. per lb. In both the instances stated there were circumstances to account satisfactorily for the decline in London, and we do not mention them for the purpose of unduly asserting the importance of this market, but they are at least evidence that two most favourable opportunities were lost to the importers.

WOOL EXPORTS.—A good demand has existed during the greater part of the year, chiefly for fine Colonial, which shows considerable increase. The alteration of the American Tariff admitting wools costing 20 cents (10d.) per lb. entirely free of duty after the 1st July, caused in anticipation a very brisk demand both in this country as well as abroad for all low descriptions, and, owing to the scarcity at that period of the year, prices were considerably enhanced in consequence. Notwithstanding the liberal scale of imports, the increase has been almost absorbed by the greatly increased quantity re-exported, and the supply on hand embraces a comparatively small proportion of really saleable descriptions.

AUSTRALIA.—The first sales of the year continued from the 26th February to the 17th March, and the quantity of fine colonial offered was 41,375 bales, including 18,744 bales Cape of Good Hope. The interval between the previous sales was longer than usual, and the stocks being extremely light, these sales opened with considerable spirit at an advance upon November rates of 2d. to 3d. per lb. on Australian, and 2d. per lb. on Cape. There was much apprehension with part of the trade, owing to the small supply announced, and it is probable that even a larger advance would have resulted but for the very opportune additions of new arrivals just before the sales commenced. The opening prices were firmly maintained for about the first week until pressing demands had been satisfied, and the dissolution of Parliament occurring at the time, at once caused a reaction, and the advance was almost entirely lost before the close. The second series continued from the 30th April to 29th May, consisting of 62,143 bales colonial, including 7,604 bales Cape. The quantity was larger than usual for this period; during the first fortnight prices showed a decline of 1½d. per lb. from the close of the previous sales, and as they progressed, a little further weakness for a short

time ensued, which however was fully recovered before the termination. The General Election, which had just taken place, had proved a great hindrance to business, and the prevailing high rate of money determined home buyers to act with great caution, and their operations were very trifling till towards the close; on the other hand, foreign buyers being without stocks, and finding an excellent assortment of first-class wools, came out very strong on this occasion, particularly at the beginning, and their purchases were very extensive. The third series continued from 16th July to the 22nd of August, and the quantity of fine colonial was 80,306 bales, including 12,452 bales Cape. Prices having gone very high at the German wool fairs and all over the continent, the same being the case with our own clip, these sales opened under very favourable auspices, aided by the promising appearance of the growing crops, and the relaxation in the Money Market. Foreign buyers again appeared in great numbers, operating very freely, and, notwithstanding the unusually large quantity, (of 2½ millions sterling value,) and the great caution still evinced by home buyers, an advance was established at the commencement of 1½d. per lb., and after a short time a further improvement took place of 1d. to 1½d. per lb., which was supported to the close. At the fourth and last series of the year, which took place from the 12th November to the 4th of December, the quantity of fine colonial was 44,873 bales, including 16,853 bales Cape. These sales opened under circumstances of extreme depression (the minimum Bank of England rate having been only a few days before raised to 10 per cent.!) at a decline from the closing rates of the previous sale of 2d. to 3d. per lb.; but as they continued under the influence of increased pressure, a still further reduction was established of 1d. per lb., chiefly applicable to wools in faulty condition, which, being in great superabundance, increased the prevailing heaviness, and notwithstanding the frequent withdrawals (which were partly again introduced into subsequent catalogues) failed to arrest the decline. Sydney wools show improved management, which is also particularly observable in Tasmanian flocks. This is not altogether the case with Port Philip wools, although, on the whole, the condition has been favourable. New Zealand wools are increasing in favour, owing to the peculiarly healthy growth, and the only drawback is their imperfect condition. Adelaide wools exhibit considerable improvement, and although the greater part imported last year has been in the grease, we do not look upon this as any impediment to their usefulness, as the prejudice even in this country against unwashed wools is much abated. It is rather a serious matter to notice that for several years the total receipts from the colonies have been almost stationary, while during the past year there has actually been a decrease, and notwithstanding the facilities for early shipments, the quantity still to come forward for the next sales will be very small.

Cape of Good Hope shows a continuous and rapidly increasing supply. There has been a marked improvement in the growth of the wool of late years, and such flocks as are well managed are now much esteemed both by home and foreign buyers. It is, however, much to be regretted that a considerable portion has been of imperfect growth, arising from the practice of shearing twice during the year, which cannot be too strongly deprecated, being both injurious to the animal and the quality of the wool, for whatever the grower may gain in quantity is more than absorbed by the deficiency in price, such wools besides being a very uncurrent sale. This system is by no means uncommon in some parts of Germany and Hungary, and it is principally by the German and Dutch colonists that this very objectionable custom has been practised.

Germany.—The growth appears to be stationary if not retrograding, and is by no means adequate to the increasing domestic wants there. The import is no longer considered worth following, and is chiefly confined to lambs' wool, and Hungarian and other medium qualities in the spring of the year, when our market is usually buoyant and prices are high.

Spanish and Portugal.—The receipts as well as demand for the former have almost ceased, and they are chiefly sent to France, where they are more estimated than in this country. Estremadura wools are at all times a favourite article here, provided they are in good condition, being of a useful medium quality; on the other hand, the heavy and gummy descriptions are mostly of uncurrent sale, except in a very brisk market. Long Oporto Fleece met with a ready sale during the greater part of the year at full prices, but the late stagnation in the demand for English Combing Wools has rendered them for the time almost unsaleable. Cotts and Lambs have generally been disposed of on arrival.

United States.—In our last annual report we pointed rather significantly to the probability of an early alteration in their tariff, which took place soon after, admitting wools after the 1st July, not exceeding 20 cents per lb., entirely free of duty, other descriptions being subject to 24 per cent. ad valorem. Although this is a very imperfect measure, it is at the same time an important step gained, and was not carried without great agitation, there being a strong interest opposed to it, and it was only passed at the last moment before the rising of Congress. This at once caused a very active demand for all descriptions, and the supplies thus directed to that quarter would, even under the most favourable circumstances, have probably proved excessive; but arriving chiefly during the period the panic was severe, and sales altogether impracticable, a large quantity was at once re-shipped to this country, of which a great portion are very unsuited to our consumption. We have also received 1,400 bags of the domestic growth of the United States. None of these wools have reached us since 1847, when they were subsequently chiefly bought up for re-shipment. Although we notice considerable improvement both in the wools themselves, as well as in their condition, still in the latter respect there is much to be desired, and arriving too at a most unfavourable season, they have failed to engage the attention of the home trade to the extent which we think their merits justly deserve; but we do not doubt that in the spring, when stocks of Port Philip, New Zealand, and Van Diemen's Land will be light, they will meet with favour, and in the meantime the trade will have had an opportunity of fairly testing them.

Buenos Ayres and River Plate.—The direct imports have been to a full average extent; and a fair quantity besides has reached us through Belgium and Italy. Early in the year, better qualities engaged considerable attention, and the first arrivals, both of washed and greasy, were sold at once at extreme prices; but the most favourable period of the year was in a great measure lost by the interruption to business soon afterwards caused by the general election. Some quantity was forced off at extremely low rates, which completely unsettled the market; and, for some time, very little business was done. Prices, however, soon rallied, and sales to some extent were made, at from 1s. 10d. to 2s. 1½d. for good-conditioned parcels; but both Merinos and Mestizos in wasty condition, and particularly burry, have not been in much favour. Of common qualities the supply has been limited; and, for the present, we cannot encourage importations. Cordova as well as Santiago wools are well adapted to our wants, and will generally meet with ready sale; but the latter are open to objection on account of the burr.

Peruvian and Alpaca.—There has again been a large increase in the supply of sheep's wool. At intervals it has been operated in pretty freely, but, on the whole, has not engaged much favour. Alpaca shows greatly-diminished receipts, owing to the civil war and the blockade of the principal ports during the latter months; and the stocks there awaiting shipment are reported to be very small. The demand has been good throughout the year; and sales have been principally made for arrival. The high prices ruling here for some time past would no doubt have encouraged a full supply, had not the impediments to shipments existed to which we have referred; and it will necessarily continue light for some time to come.

East India.—The total receipts show a steady increase, and no less than five-sixths have reached this market, a proof that it continues to be regarded as the most favourable for the sale of this description. Our public sales have attracted considerable attention; and at the last October series 15,723 bales were disposed of, which only a short time back would have been considered impracticable; nevertheless the whole was taken freely by the trade, and the last day's sale showed even increased spirit. Persian and other long-stapled kinds of well-bred wools have been in great favour, and on most occasions have brought very extreme prices, owing to the high value of English combing wools, for which they were required as a substitute. These kinds experienced a serious reaction at the late London

public sales, in consequence of the heaviness of the market for English wools. It is now some time since we first drew attention to this particular class; and we would again repeat, that any trouble and expense would be amply repaid in increasing the growth of this very useful description, and we are of opinion that the most extreme prices they have yet attained have not exceeded their intrinsic merits; they have hitherto been chiefly tried for experiments, and as they become better known they will command a wider consumption and a higher permanent value.

CHINA.—The import continues on a limited scale, and so ar from any improvement the condition has been even worse han usual. This wool could be used with advantage, if a moderate degree of care was taken to make it acceptable to our consumers.

RUSSIA shows a large increase, chiefly of Donskoy. Until the latter part of this year Donskoy wools were in fair demand, while superior parcels were much sought after, and were readily saleable at 11d. per lb. Sales were made at this price nett cash, and it is probable that 11½d. per lb. might have been obtained, if a further quantity of superior wool had been available at the time. It is to be regretted that the quantity of healthy-grown bright combing wool is much diminished, the great bulk being very cotty and short in staple, besides very scurfy and containing a large proportion of broken wool. The quotations abroad for this article are still much above what can be obtained here. Autumn and Lambs' have not engaged much attention. There has been very little done in brook-washed, or scoured, but for both we consider the prospects favourable. These kinds have been much sought after in Russia, and already some extensive contracts have been made for next season's delivery in August and September, for Continental account, at very full prices.

MEDITERRANEAN.—There has been a moderate increase, but the various kinds do not call for particular comment, having comprised a large proportion of inferior kinds, imported chiefly with the view of meeting the demand for the United States, of which a large quantity still remains on hand.

EGYPTIAN has fallen much in discredit, owing to the great prevalence of spurious kinds attempted to be passed off under this name. The pure glossy article continues as much in favour as ever, but is now rarely met with except mixed with Syria, and other inferior wools, which are altogether unsuited to the same purpose.

TURKEY GOAT'S WOOL OR MOHAIR.—Although the import has been on rather a liberal scale, there has been a good demand throughout the year, and at no time has there been any accumulation of stocks, sales having been largely entered into for arribal at advancing rates.

ICELAND.—The supply has not equalled the previous year, but it has increased in favour with the new branches of the trade, owing to its peculiar brightness of colour and softness. Early in the season sales were made, both on the spot and for arrival, at 13½d. per lb.; but subsequently, some transactions took place at 12d. to 12½d. per lb., chiefly for Southland wool. The remaining stock consists principally of Northland, including some parcels of very superior quality and length.

BARBARY.—The import has been below an average. Medium and fine qualities in good condition generally meet with ready sale, but for the most part they are still open to the objection of being very sandy, burry, and in damp condition, which render them almost unmarketable.

DOMESTIC WOOLS.—Prices of ENGLISH have been well maintained, with a general tendency to advance till the late panic occurred, and since then they have been altogether nominal. Some very low sales have been reported, made under circumstances of peculiar pressure, and can therefore, hardly be considered any fair criterion of value. The stock remaining in growers' hands is particularly light, and from the absence of purchasers for several months, consumers are supposed to be pretty well reduced in stock. During the last week a good many buyers have been looking round, and any lots offered at moderate rates have been freely accepted, so that prices will soon assume a fixed value. IN IRELAND the same limited supply exists, and at the present time, owing to the large quantity exported, the whole country could probably not furnish more than in former years might readily have been met with in one single district. SCOTCH.—*Laid Cheviot* has been in very moderate demand, and prices have been chiefly maintained by speculative purchases, rather indiscriminately entered into, which were subsequently thrown upon the market under very unfavourable circumstances, entailing very heavy losses and a depreciation in value disproportionate to any other description at the time. *Laid Highland*, on the contrary, has maintained a high price, and been much dearer than corresponding qualities of foreign.

SHEEP SKINS have met with uniformly good demand during the greater part of the year, and have been saleable on arrival at satisfactory prices; but of late there has been a great desire to press sales of *English* skins, and there has been little attention directed to *Foreign*, of which there is only a trifling stock.

Liverpool, Jan. 1st. HUGHES AND RONALD,
Wool Brokers.

TRADE OF THE PORT OF HULL.

REPORT FOR THE YEAR 1857.

During the eventful year now closing, the business of this port has been carried on on a very extensive scale, as the amounts of tonnage and of the tabulated exports and imports fully manifest. The severe money pressure which has prevailed for the last few months naturally restricted transactions and depressed prices, causing also a great accumulation of stocks of many of our leading articles of import. The Bank of England having now, however, reduced the rate of discount, and an easier position in our monetary affairs resulting, will, it is confidently anticipated, cause a resumption of business in this quarter, and a greater activity of the general trade of the country.

The gross tonnage entering the port this year amounts to 1,085,390, against 1,076,787 last year, showing an increase of 8,603 tons. The number of ships and vessels reported inward on foreign voyages is 3,033, tonnage 738,082, whilst last year the number was 3,157, and tonnage 743,157, showing a trifling decrease. The tonnage of steam vessels in the foreign trade this year is 47,240, against 28,229 in 1856, and 14,392 in 1855, exhibiting an increase in the number and tonnage of our steamers of nearly 100 per cent. from year to year. The year 1856, it will be remembered, greatly exceeded, in consequence of the cessation of hostilities with Russia, any previous year in the extent of our trade.

GRAIN.—We have again to record at the close of this year a great reduction in the value of all cereal produce, which, at a time like the present, when the manufacturing interests of the country have hardly begun to recover from the shock of the commercial disasters above alluded to, must be a source of congratulation to the consuming public, the price of the staple article of food in this country being now lower than it has been since the summer of 1853. It is no part of our duty to venture an opinion as to the future range of prices of an article so changeable and so dependent on seasons as grain; but the value is now reduced to such a point that the agricultural interest already complain of unremunerative prices; and when such is the case, it is generally admitted—so intimate is the connexion between them—that the manufacturing interests of the country must also be in some measure affected *pari passu*. Already the growers appear to have made a stand; and for the above reason, and the failure of the potato crop, as well as the prospects of a resumption of activity in our manufacturing districts, an upward movement in price is by no means improbable, the extent of which will greatly depend upon the supplies that are likely to reach us from America and other corn producing countries before the coming harvest. At the commencement of the year the value of good red English wheat

was about 60s. per qr., with a prospect of a still further advance, as the previous crop—not only in this country, but on the continent—was defective both in quantity and quality, added to which a considerable demand for export existed from the South of Europe. Prices, however, instead of improving, rather declined, large supplies from the Black Sea and Mediterranean having satisfied the requirements of the Peninsula. At the end of the first quarter, in consequence of more liberal supplies from our growers, and larger imports from abroad than were calculated on, prices gave way 5s. per qr. on English, and 4s. to 5s. on foreign sorts. A better demand however set in, and by the end of May the value had more than recovered the depression existing in the four previous months; and at the end of June English red was quoted 68s. to 70s., mixed Danzig 66s. to 70s., Baltic red 60s. to 64s., and Russian 58s. to 62s. per qr. A good consumptive demand nevertheless continued, and in the month of June prices appear to have reached their highest point. The approach of the harvest at this time was signalized by the most brilliant weather, and the splendid appearance of the wheat crop was all that could be desired. Prices accordingly soon gave way; in fact, a sort of weather panic appeared to influence all parties connected with the trade, and a decline of 10s. per qr. was submitted to before the end of July. In this locality heavy storms, attended with severe floods, endangered the favourable ingathering of the crops, a portion of which had eventually to be harvested in a state hardly fit for human food. Still, taking the country throughout, it is generally admitted that this year's crop of wheat is fully an average, both as regards quantity and quality; and this appears to be fully borne out by the general, yet important, reduction in value. At the end of August, at which unusually early period the bulk of the wheat crop was secured, new English red of first quality was worth 60s. to 63s., old English 60s., Baltic red 55s. to 58s., and white 60s. to 62s. per qr. From this date the value remained pretty steady, until affected by a more stringent state of monetary affairs; this increasing in intensity, drove prices rapidly downward until the middle of the month of November, at which time we appear to have reached the lowest point, red English wheat having been forced off at 45s. per qr., 63lbs.; Baltic red for 46s. to 48s., choice white 52s. to 54s. Since then the gradual and apparently sound improvement in commercial matters generally, combined with a good consumptive demand, partly arising from the failure of that valuable esculent the potato, the prospect of a cessation of supplies from abroad of any magnitude for some time to come, the tone of the market has gradually improved, buyers generally show less hesitation in operating, and prices have advanced on all good useful wheats 2s. to 3s. per qr., at which advance we close the year, with a good steady trade. The stock on hand is estimated at 74,000 qrs., against 40,000 qrs. last year.

Barley.—The import of this cereal during the year has been on a very liberal scale, exceeding any since 1850, being 250,682 qrs. These large supplies have principally reached us from the Baltic, whence little has been drawn for many years past, and part from Turkey, where the cultivation has very much improved, as shown by the quality of the shipments. This grain has during the present year commanded high prices, English malting up to the close of the malting season having brought 46s. to 48s. per qr. About this time arrivals to an almost unprecedented extent from Silesia and the Baltic Ports affected its value, which declined 3s. to 4s. per qr.; but well-founded accounts of continued drought on the Continent endangering the crop, produced a speculative demand for everything of malting quality, and prices soon rallied. Monetary causes, however, having affected this in common with every other article of import, the value declined, and at the close of the year quotations were 34s. to 36s. for English, and 32s. to 35s. for foreign malting; whilst grinding stands at 28s. to 29s. for stout, and 27s. to 27s. 6d. for thin qualities. The stock on hand is 4,000 qrs., against 31,500 the previous year.

Oats.—The import this year consists of 99,500 qrs., against 42,045 the preceding one. This grain has fluctuated less than any other; prices scarcely varied from the commencement of the year until April and May, when, owing to the drought and the backwardness of the season, an advance of 2s. per qr. was obtained; this, however, was of no long duration, prices since having gradually followed in the wake of other articles, and chose considerably lower, especially for Russian, of which the major part of the stock here at present consists, say 28,000 qrs., against 3,000 qrs. in 1856.

Beans.—The import shows a small decrease as compared with last year, the same being 57,956 qrs. this, and 69,756 up to the end of last year. The demand has been good throughout the year, and, with the exception of some portion of Egyptian supplies, which went to granary on arrival, nearly all the supplies from the Baltic and nearer ports were realized ex-ship, and the stock is now very light. In the first and second quarters of the year prices varied from 38s. to 44s., third from 43s. to 46s., October and November 42s. to 43s., and the closing prices are now 38s. to 39s. per qr., all 63lbs. per bush. Stock 9,500 qrs., against about same quantity last year.

Peas.—The supplies have been very large in comparison with those of the preceding year, when they reached only 4,736 qrs.; whereas this year they amount to 24,004 qrs. Although the demand has been confined to mere consumption, supplies have found ready sale, and the year closes with but a small stock. In the first half-year prices ruled from 38s. to 42s.; during the following five months, from 40s. to 48s.; and the present value is 38s. to 42s. per qr. of 63lbs. Stocks small—say 2,500 qrs.

Clover and other Agricultural Seeds.—During the present year seeds have been subjected to great fluctuations, particularly red cloverseed, which early in January opened at rather moderate prices; but in consequence of fine genial weather prevailing from the middle of that month to the second week in March, an active demand appeared, and was continued up to this period for all descriptions of seeds, and prices were well maintained, whilst in some cases there was a considerable advance, red cloverseed having improved in value since the opening of the year 8s. to 10s. per cwt. About the middle of March, however, from unfavourable weather, the trade was almost suspended. Notwithstanding this great curtailment of the consumption, the stocks at the close of the season were by no means extensive. The new crop of red cloverseed promises well as to quality, particularly in Holland and Belgium, from both of which countries we have had some arrivals of very choice seed; the breadth that has been cultivated, however, is said to have been small. In Germany the crop has not been well spoken of as to quality, in quantity pretty fair. In France moderate, with an average quality. In this country the crop at one time was expected to be an abundant one; but in consequence of the long continuance of wet weather at the time of maturing, the seed was much injured both as to quality and production; but it is still thought there will be a tolerable yield in some districts of rather inferior seed. The new crop of white in Germany, whence we receive our principal supplies, is reported to be very much short of last year, both in quality and quantity, particularly as respects the latter, and under this impression prices have been well supported, fine and middling old seed having sold the last few weeks at higher prices than such qualities would have produced at the close of the season and to the present time. We have had very small arrivals of new seed.

Linseed.—Of this article our import has been again very large, being only a few thousand quarters deficient of last year's, which was the greatest import recorded. The year commenced with considerable stock in warehouse; notwithstanding which, the value of seed steadily improved, until Black Sea qualities attained 68s. per qr. in March. Our imports becoming large about this time, prices gradually gave way about 5s., the value in April of Taganrog seed being 62s. to 63s. For the next two or three months the market fluctuated to the extent of 2s. to 3s. per qr. in favour of sellers, but prices were generally well maintained until the development of the financial crisis in the beginning of October, which influenced the value of this article very severely, and in the course of two months a decline took place on fine seeds of about 15s. per qr. from the utmost value; common qualities suffering in proportion, the prices at the close of the year being 49s. to 50s. for fair quality of Taganrog and Odessa seed, 46s. to 48s. fine Petersburg 52lbs., 43s. to 45s. for medium, while inferior are not saleable at beyond 38s. to 40s., weighed 51lbs. The position of of the crushing trade during the year has been of an unsatisfactory nature, the value of seed having been kept up at an extraordinary high point, which generally precluded the manufacturer from carrying on his business in a profitable manner, the raw material being so much above the relative

value of its produce. The great fall in prices has been, to some extent, a natural consequence of this state of things; and values having now assumed a level more in accordance with that of previous years, there is every probability of this important branch of our trade assuming a more healthy condition. The stock in public warehouses and in crushers' hands we estimate at 170,000 qrs., being more than double that of the previous year, and a larger stock than has ever been held over in this port.

LINSEED OIL.—The stocks of this article at the commencement of the year were light, the value being about 37s. 6d. per cwt. An improved demand, partly speculative, developed itself early, the highest point for the season having been attained about the middle of February, when we quoted close upon 42s. per cwt., after which a gradual decline of 2s. to 3s took place, which continued with occasional fluctuations, until prices gave way in sympathy with the raw material, as above stated, the lowest point attained being 27s. per cwt. We however close the year with a slight improvement, the price being 28s. 3d. to 28s. 6d. per cwt. The natural effect of a high range of prices during the year has been a considerable falling off in the extent of our exports to the continent, which are 7,184 tons, against 12,549 tons in 1856. The stocks, which were considerable two months ago, have been much reduced, and the low price has attracted the attention of speculative purchasers for forward delivery, at prices about 2s. per cwt. above the value on the spot, thereby showing a greater degree of confidence in the article than has been evinced for many weeks past.

LINSEED CAKES.—The year commenced with small stocks, and prices of best Hull-make at £10 10s. per ton. A brisk demand towards the end of January, backed by limited supplies, drove prices up to £12 2s. 6d., which was the highest figure they reached during the year. Up to the month of June the demand was slow, at a decline of 30s. per ton, when, owing to the dry scorching weather, they became in great request, at advancing rates, say £11 for best quality, with a considerable demand for forward delivery at 5s. to 10s. more. There was little variation in the value for immediate delivery up to Oct., when the fine autumnal weather, which reached far into Dec., interfered with the demand, and the value gradually fell to £9 15s. per ton. The stocks held by crushers are comparatively light, and many makers decline working at the present low rates of this article and oil, owing to the unremunerative nature of the business. Foreign of good quality have been in fair demand during the year; these are now in small supply, a great portion of the present stock being inferior in quality and condition. The imports of foreign this year show a considerable increase, being 14,261 tons, against 9,547 tons at the close of last year. A steady consumptive demand has been experienced throughout the year for all good foreign qualities, at proportionate prices to the English manufacture, say from £8 to £8 5s. per ton, for "small-shaped" cakes. An increased proportion of the imports consisted of large English-shaped cakes, which, on account of their form and superior quality to the ordinary make, commanded prices approximate to the value of best English manufacture. Towards the close of the year arrivals have been moderate; but the consumption of cakes, on account of the mildness of the season, has been equally limited. Stocks in warehouse are considered of fair extent, being principally of low qualities, and consisting of about 2,500 tons, against 1,300 tons the year before.

RAPESEED.—The import of this article considerably exceeds previous years, being 6,100 lasts, against 1,690 and 1,404 lasts the two previous years. Prices of new German seed ruled in the autumn months about £35 to about £36 per last; since then, owing to the languid demand for oil, the value has receded to £29 to £30, but these prices must be considered as nominal, purchasers for the present being quite out of the market. Stocks are, however, very light, and with an improvement in manufacturing districts, a better demand may be expected. The bulk of the imports has this year been on crushers' account, little appearing in our market.

RAPESEED OIL.—The demand throughout the year has continued to be a purely consumptive one, and at no time was there anything worthy of particular note in the value or demand of either English or foreign, the import of the latter having been on a very limited scale. The supply exceeding the demand during the few last months, brought prices down to £42 for brown, and £44 to £45 for pale oil, at which the year closes.

RAPE CAKES.—The value of this article has ruled unusually the same throughout the year, there having been a fair demand for good green qualities at £6 to £6 10s. until the last few months, when they declined 10s. to 15s. per ton, Foreign cakes have fluctuated from £5 7s. 6d. to £5 12s. 6d. per ton, their present value, up to £6 15s. per ton, the highest price reached in March and August. Imports went into consumption as they arrived, and there consequently has been no accumulation of stock.

OLIVE OIL.—The import this year has been 3,410 tuns against 4,920 tuns in 1856, the present stock remaining a trifle over that of last year at the same time. Prices, as was anticipated, were well maintained with little variation during the first nine months of the year; subsequently, in consequence of the reports of good crops, larger supplies than usual of Rapeseed, and forced sales during the money panic, prices have ruled very irregular, and are expected to continue moderate for some time to come, owing to favourable crops, and from the fact of the largest holder at Naples realizing all his heavy stock, causing a reduction in the price of about £15 per tun free on board from the highest point.

FLAX.—The import for the year has been 19,466 tons, against 18,941 tons in 1856, 14,909 tons in 1855, and 12,271 tons in 1854. Of the present year's import, 8,870 tons are from the Baltic, against 9,030 tons in 1856, 7,465 tons in 1855, and 4,331 tons in 1854; the remaining quantities were received as follows, viz.: 3,852 tons from Holland, 5,583 tons from Belgium, 866 tons from France, and from sundry ports 295 tons. The imports of Tow and Codilla amount to 3,381 tons, of which 2,323 came from St. Petersburg, and only 20 tons from Archangel. During the season the consumption has been of a healthy character, but since the money panic prices have been more irregular, and the demand limited to the actual requirements of the spinners, the mills being put on short time. It must, however, be remarked, that during the late depression the linen trade has suffered much less than any of the leading branches of the manufactures of the country. The stock of Flax is moderate at this port, and a revival in the consumption is confidently anticipated.

HEMP.—Of this article the imports are 1,575 tons from Petersburg, 1,157 tons from Riga, 62 tons from Bombay, and 145 tons from sundries, making a total of 2,939 tons, against 4,043 tons in 1856, 3,341 tons in 1855, and 2,690 tons in 1854. The consumption of Hemp for roping purposes is evidently much curtailed by many substitutes now brought into use, but the short Hemps, for manufacturing purposes, are much demanded. The prices of clean Hemp during the year have been much affected by the extensive speculations entered into during the winter and spring at St. Petersburg. In addition to the influence of the late money panic, the heavy stock of clean held in London has greatly increased the decline in value, and takes away any present prospect of advance in prices.

TALLOW.—The largest proportion of our import into this place, which this year reached 3,000 tons against 2,160 last year, goes direct to the consumers, or into the hands of Liverpool houses, the prices being regulated by those of the London markets, to a very great extent, in which the fluctuations have this year been remarkable. The stock on hand is about 2,000 casks against 500 last year, and the value 53s. per cwt.

IRON.—Our imports this year are 34,000 tons against 32,000 in 1856. The prospect of good demand in the beginning of the year was realized to some extent, a considerable business passing during the spring months at slightly advanced prices. A fair proportion of our large supplies have gone into consumption; but for the last few months the influence of the money panic, which from the extensive transactions with the U. S. was first felt in this trade, has rendered business impracticable, and we close the year with considerable stocks on hand, which can only be reduced by a resumption of activity in our manufacturing districts, and a sound natural demand from other countries.

HIDES.—The imports during the year have been very limited of all sorts of continental hides, except Petersburg kips, of which rather a large quantity has come. Prices ruled very high up to September; since then a very rapid decline took place, and present quotations, though in some instances 30 to 40 per cent. less, must be considered nominal from the absence of buyers. The stock is small in this market.

CATTLE BONES.—The import this year is 14,261 tons, against 16,200 in '56. From its commencement a gradual

advance in prices of bones and bone ash took place, arising from a continued good demand and short supplies. For weeks we had no arrival, a better market having been found for the article in France and Holland. As parcels dropped in they were taken up at prices varying from £6 10s. to £6 15s., and we close the year at this last figure, stocks being 228 tons, against 3,000 last year.

TAR.—The imports of this article in the fore part of the summer up to September continued small, in consequence of which the price, instead of ruling somewhat below, kept at about a par with the rates obtainable during the same period in London; Stockholm tar keeping up, with little variation, at about 16s. per barrel. Towards the end of September, the supply, through larger arrivals, becoming more abundant, the price receded to 14s., and later in the season down to about 12s. 6d., at which the article may now be quoted in first hands. The imports, including Archangel tar, which description in a general way does not come much upon the market, reaches a total of 26,818 barrels, being in excess of that of last year, which was 22,531 barrels. Of this import, about 3,500 barrels have been landed for higher prices, and one parcel of about 1,700 barrels is now in course of sale in small quantities from the importing ship.

TURPENTINE.—The direct import this year is 7,353 barrels against 9,376 barrels last year; but this affords no criterion whatever of the quantity used by distillers in this quarter, who receive by far the greater proportion used by them from London. The value of this article remained pretty steady during the first part of the year, but in the month of July, in consequence of a reported scarcity in the United States, prices advanced to 45s. per cwt. This high value was not, however, long maintained, and the year closes at 33s. to 34s., with a small stock on hand.

WOOD.—The import this year has shown a large decrease on the preceding one, as will be observed by the tablas. The demand throughout the year has been very languid at generally declining prices, until they reached their present position, a lower value than has existed for many years past, especially with regard to Baltic goods. These prices are difficult to quote, arising from the irregular nature of recent transactions, and the result of the disturbance in our monetary affairs. The stocks on hand are considerable, but not above the requirements of a return to a nominal condition of commercial matters; and as the prospect of this is no longer doubtful, a good demand is anticipated in the ensuing year.

SHIPPING.—The past year has been a very unsatisfactory one for the shipping interest generally, and very few vessels can have done much good. Our local trade has had more than its full share of the general depression, for although the gross tonnage into the port appears large, much of it is owing to the rapid passages and continuous arrival of steamers, and a more than ordinary proportion of ships arriving, have been seeking vessels, fixed at unremunerative rates on the other side. The Colonial trade has been as dull as it could well be. Freights have been about 35s. Quebec, and 90s. to 95s. Richibucto, Buctouche, Miramachi, &c., with very little doing. Baltic wood freights have also been scarcely worth attention, and have varied very little. During the season the rates have ruled from Dantzic, 15s. to 17s.; Memel, 15s. 6d. to 17s. 6d.; Sundswall and Holmsund, 19s. to 20s.; Windau, 17s. to 18s. 6d.; Riga, 25s. to 27s.; Cronstad, 42s. 6d. to 47s. 6d.; Wyburg, Fredrickshamn, 47s. 6d. to 52s. 6d.; Archangel, 4s. 9d, seed; Riga, 42s. 6d. flax. At the close of the year seeking ships have had to leave the Russian and some of the Prussian ports *in ballast*. Altogether, shipowners may be very glad to turn their backs upon 1857, especially as there is rather a hopeful feeling as to its successor.

P. BRUCE,
Secretary to the Hull Chamber of Commerce.

EXPERIMENTS WITH DIFFERENT MANURES.

Some few weeks ago a correspondent suggested that farmers who had been making experiments with different kinds of manure should send to you an account of them, with the results obtained, and you expressed your willingness to publish them. I take the liberty of reporting to you a statement of experiments made by me on my turnip crops during three years, and hope you will find room for it. I vouch for its accuracy, everything connected with the experiments, from the weighing of the manures to the pulling and weighing of the turnips, having been done by my own hands. I may mention that none of the manures were procured expressly for the purpose of making a comparative trial, but were all portions of larger quantities bought by myself or my father at Over Roxburgh farm.

In 1855.—Sown June 12, weighed Nov. 21. The plants came very badly away; and, with an unsuitable season, and a stiff clayey undrained soil, the crop was a very poor one.

In 1856 the braird was good and equal. Soon all the bone manures took a decided lead, which they kept till about harvest, when their strength seemed exhausted, and their crops proved deficient. Sown June 11, and weighed Dec. 2. The field is clay, but drained and limed the previous year.

In 1857 the bone manures showed as they did in the previous year, early, but without permanency. The sawdust steeping was an idea of my own, and will be tried next year on a more extensive scale by several farmers. The soil is clay, drained and limed five years ago. Sown June 16, and weighed Dec. 9. An excellent crop, much above the average of the district. In each year the turnips were of the common white globe variety. THOS. THOMSON.

Millfield, Kelso, Dec. 9, 1857.

REPORT BY JUDGES ON FOWLER'S STEAM-PLOUGH.

The Highland and Agricultural Society's *Premium-Book*, published in February, 1857, contained the following intimation :—

"For the practical application of steam or water-power to the ploughing or digging of land, £200. The merits of the invention will be tested by its general applicability, by the character of its work, and by its saving in time, labour, and outlay, as compared with horse-power. The inventor must be prepared to deliver his machine at Stirling by the 1st of October, and to put it in practical operation on such farm in the neighbourhood of that town, and to work it for such a period, and under such regulations, as the Directors may determine—the object being to test its capabilities by continued work, and not by a mere show trial."

The utmost pains were taken to make the premium known to implement makers, in the hope of securing competition; and though for some time there was a prospect of this, eventually Mr. John Fowler, jun., 28, Cornhill, London, was the only party who appeared.

The following gentlemen were named as a committee of judges to test the merits of Mr. Fowler's invention, and to determine how far he was deserving of the premium offered: Messrs. John Miller, of Leithen; James Stirling, C.E., Edinburgh; John Dickson, farmer, Saughton Mains; John Finnie, farmer, Swanston; John Gibson, farmer, Woolmet; William Henderson, farmer, Craigarnhall; and Robert Patterson, Offers.

The neighbourhood of Stirling having been fixed for the trial, all local arrangements were left to the supervision of the Stirlingshire Agricultural Society, by whom the farm of Stewarthall, possessed by Mr. William Forrester, was selected as the place, and the 20th of October named as the time for the trial; and it was resolved that, previous to the public being admitted to inspect the operations, they should be privately conducted for at least three days in the presence of the judges exclusively.

Before entering upon a narrative of the proceedings, it may probably not be out of place to describe, generally, the machinery brought forward by Mr. Fowler. It consists of three main parts—viz., *the Plough*, *the Steam-engine* and gearing connected therewith, and *the Anchor*.

The *plough*, which is constructed to turn over four ordinary furrows at the same time, consists of a strong framing about 20 feet in length, supported at the centre on two wheels, one of which travels in the last formed furrow, and the other upon the "land," and by adjustment as to relative heights on these wheels the apparatus is brought into train, and the depth of the furrow to be turned over determined. The two ends of the framing join each other at a considerable angle at the centre, so that when the one end is nearly horizontal and at work, the other is raised at an angle of about 35 degrees, and is thus kept entirely clear of the ground; each end of the framing is supplied with four ordinary plough-heads (share, sock, and mould) closely following each other, and each placed so as to take in and turn over a breadth of 10 inches, or 3 feet 4 inches for the four at each operation. The plough-heads on the two ends of the framing being in every respect reversed to each other, the machine does not require to be turned at the end of the furrow, but by simply elevating the end of the frame last at work, the other end, which balances it, is brought down to working position, and by means of the two carrying-wheels the necessary lateral motion of 3 feet 4 inches is easily and correctly given by the man in charge, and the plough is at once ready for turning over another set of furrows by being pulled in the opposite direction. This pulling is performed in both directions by means of a steel-wire rope of about ¾ inch diameter, passing from the engine at the one end of the field to the anchor at the other end, and back to the engine again.

The *steam-engine* used by Mr. Fowler is a portable one, very similar to those now so much employed in England for thrashing and other agricultural purposes. For greater facility in getting into motion, and stopping, and otherwise for bringing the engine more completely under the control of the engineman, it is fitted with two steam cylinders working on a double crank at right angles to each other, as in locomotive engines. The cylinders and crank-shaft are placed on and fixed to the upper part of the boiler, and the motion is carried down from the crank-shaft by means of an upright shaft fitted with mitre gear and reversing clutches to two drums, upon which the wire ropes are alternately coiled and uncoiled during the operation of ploughing. The drums are placed horizontally under the framing of the engine, and their gearing is so arranged that either can be at pleasure thrown into gear with the upright shaft, so that, while the one is set loose to allow the uncoiling of the wire rope, the other is at work dragging the plough. The drums with the rope partially coiled on have an effective average diameter of about 3 feet, and are 11 inches in breadth each; by means of the connecting gearing already alluded to, the drums are made to take on the wire rope at the rate of from 2¼ to 2¾ inches an hour, equal to about the rate at which the pistons travel. The pistons being 6½ inches diameter, or 33 square inches each in area, and the steam in the boiler being at say 65lbs. per square inch, will exert a tractive strain on the wire rope (allowing a half for loss by friction, &c.) of 2,140 lbs., or nearly one ton. The engine and plough being placed at opposite ends of the field, it is evident that the plough could be drawn towards the engine, and the first set of the furrows turned over, by means of a single rope attached to the plough, and the other end of the rope coiled up on one of the drums of the engine; but to effect the returning draught it is necessary either to employ another engine with the necessary apparatus at the other end of the field, or, by passing another rope also fixed to the plough over a sheave fixed there, and returning and connecting its other end with the second drum of the engine, to work both directions by one engine. This latter plan has been the one adopted by Mr Fowler, and the simple and ingenious apparatus to which the sheave is attachedis termed

The *anchor*. This consists of a strong low wooden frame about 10 feet long and 5 feet broad, supported when in use upon two axles or rollers; on each of which there are two thin-edged wheels or discs of malleable iron, which sink by the weight of the machine to a depth of 8 or 9 inches into the soil: they are prevented from sinking deeper by the bodies of the rollers (about 9 inches in diameter) coming in contact with the surface of the ground, and bearing up the remaining weight. To the framing between the rollers are fixed the bearings of a large horizontal sheave about 4 feet in diameter, around which the wire rope turns when the plough is being drawn away from the engine; the strain thus thrown upon the sheave, which is double the direct strain exerted on the rope by the engine, is resisted by the four discs, which, being placed at right angles to the line of traction of the plough, act like the flukes of four powerful anchors.

It will be apparent that, as the work advances, both the engine and anchor require to be moved slightly forward for every turn of the plough, so as to keep them always in the proper line of traction. This motion in the case of the anchor is ingeniously effected by means of a small capstan or crab attached to the framing, and driven by wheel-work from the large sheave. The engine is provided with a similar apparatus, but it is driven by a direct communication with the gear of the engine. These crabs give motion to their respective machines by slowly coiling up two small wire ropes, the other ends of which are fixed to pawls driven in at suitable points in advance of the machines along the ends of the field.

It may be proper to remark that the engine can be made locomotive, so as to be able to move itself along a road or about the farm without any assistance, and that it can also be so made as to be available as a power for thrashing, or any other work about the farm requiring power, as well as for ploughing. At the same time it is considered that the circumstance of Mr. Fowler's engine not being required to travel the land to be ploughed is a most important feature; and, in the progress of improvement, it may not be far distant when the engine will be enabled to do its work efficiently without the necessity of leaving a corner of the field, and thereby obviate the disadvantage of moving over it.

The trial, as already stated, commenced on the 20th of October, on a grass field consisting of a very stiff tenacious clay, and in a very unfavourable state for ploughing. A considerable extent of ploughing was accomplished, but the greater part of the time was spent in the examination of the various parts of the machinery, and of the mode in which each portion performed its part; and the result of that examination was, that although the judges were of opinion that in one or two minor points the machinery might be improved, the main principle of the apparatus brought forward by Mr. Fowler is correct, and calculated to perform its work in a satisfactory manner. On the 21st of October they had the plough put in operation with the view of testing its power in accomplishing work, and of determining the character of the work itself. The operations were carried on in the same tenacious clay-field, and, upon an experiment of several hours, they found that they might assume the work performed in such time to be about 7 imperial acres in a day of 10 hours: the furrow was in length 330 yards, and about 6 inches deep, and each 10 inches broad, or taking the four plough-heads, the breadth turned over at each operation was 3 feet 4 inches, and the work was very satisfactorily done. The cost appears to be the following: Mr. Fowler states that four men and a boy are required for his apparatus: that the judges found to be sufficient; indeed they think the work might be done by three men and two boys; the daily wages may therefore be assumed at from 13s. to 15s., according to the rate of wages, but say that it is 15s. A horse and cart are required to supply the engine with water, unless in cases where the water may be had in the field; they have, however, to assume this cost in the mean time, and they put it down at 6s. per day. The engine is worked with raw coal, and consumes in the 10 hours what can be obtained at Stirling for 6s., taking the coals at 12s. per ton; oil, and other incidentals, they take at 3s.—making, in all, a daily cost of 30s., exclusive of the tear and wear of the machinery and interest on capital. The judges have not had sufficient experience of the machinery to estimate the cost of the tear and wear, but they think that were they to say 20s. per day it would be sufficient to cover these two items. The total day's cost would in this way be 50s., and assuming the work performed to be 7 acres per day of such land as they found it, the cost would be a little more than 7s. per acre. With the view of testing this as against horse-power ploughing, Mr. Forrester was kind enough to put at the disposal of the judges a plough and pair of horses, but they found that two horses were not equal to the work of a furrow such as Mr. Fowler's plough was turning; according to their own estimate, and that of farmers well acquainted with the working of such land, and with whom they consulted, they are of opinion that such land as they had to do with, and at such a season, could not be turned over by horse-labour under a cost of 15s. per acre. According to this, therefore, there is a clear saving of fully half the cost by Fowler's plough, and the work performed is fully equal to, if not better than, what could be done by horse-labour.

It may by some be apprehended that the allowance for wear and tear is insufficient, in consequence of the liability of the wire-rope to injury from friction on sharp soils; but the risk of this is in a great measure obviated by the facilities for preventing the rope from coming into contact with the ground at all. These facilities are afforded by means of friction-sheaves mounted on small moveable carriages, and these sheaves are in number proportioned to the length of the furrow or undulations of the ground.

The judges having satisfied themselves as to the efficiency of Fowler's steam-plough for the ploughing of stiff tenacious clay-land, they had the whole apparatus removed to another farm, "Boll-for-nought," also in the possession of Mr. Forrester, and on the 22nd of October had the plough tried on a stubble-field of deep alluvial soil. The furrow on this field was considerably shorter than that on the other field, being only 220 yards long; its depth was 7 inches and its breadth 10 inches. In this experiment the quantity turned over was at the rate of nearly 10 acres in the day of 10 hours. The judges expected that the engine would have done more work than that, and probably it could when in continuous operation; but they have stated the quantity as they found it, and it will be kept in view that the short furrow tends to diminish the quantity performed. Assuming the cost per day at 50s., as formerly, the rate per acre would be about 5s.; but, on the other hand, the cost of ploughing the same land with horse power would not greatly exceed, if at all, 8s. per acre. The saving, therefore, on light land cannot be so great as it would be on heavy land—or even steep land, where power is so much required. The ploughing was very well done.

On this field the judges had the apparatus applied to trench-ploughing, and the work performed gave the greatest satisfaction, surpassing anything that could be done with horse-labour. Mr. Fowler, in trench-ploughing, did not use the same plough-frame as he did in the ordinary ploughing; the one employed was fitted up to turn two trench-furrows at each operation—each furrow was turned in two lifts, the upper lift in each case being turned into the bottom of the furrow, and the bottom lift being laid over all; and from the speed at which the plough travels, the subsoil is so completely thrown up and broken, that nothing executed by horse-labour can excel, or perhaps equal it. The trenching, 12½ inches deep, was performed at the rate of about 5½ acres per day of ten hours, and at a cost, assuming as formerly, of about 9s. per acre.

The experiments, in so far as the judges were concerned, were completed in the afternoon of the 22nd of October, having occupied a period of three days. On the 23rd and 24th the trials were continued for the satisfaction of the public, and it is believed that those who witnessed them were very generally pleased with the result. The agriculturists in the Lothians having expressed a wish to have an opportunity of witnessing the operations, the whole apparatus was removed to the

firm of Saughton Mains, near Edinburgh, possessed by Mr. Dickson, and there Mr. Fowler continued his operations for several days, with pretty much the same results. At the same time, it has to be noticed that there were one or two breakages in the machinery, which must have led to some disappointment, but these breakages were not such as to tell against the principle of working as carried out by Mr. Fowler.

Having now described the various trials gone into, the judges are called upon to express the high gratification they experienced in witnessing the performances of Mr. Fowler's plough, and the results achieved by it. They are of opinion that Mr. Fowler has satisfactorily established, that land of a certain description can be well and economically ploughed by steam; and they think it due to him to say that he highly merits the approbation of the agricultural public, for the ability, energy, and ingenuity brought by him to bear on the all-important question of turning the soil. In these circumstances, the judges recommend that the premium of £200 offered by the Society should be awarded to Mr. Fowler. At the same time, they do not desire to hold forth Mr. Fowler's apparatus as faultless; experience will in this, as in all other attempts to apply machinery, suggest improvements, and, indeed, several important modifications have been made by Mr. Fowler since the trials now described terminated; neither would the judges wish it to be inferred from their decision that the apparatus is, in terms of the condition attached to the premium, susceptible of *general application*, as, in its present form, it is not available for land on which large stones are imbedded. Nevertheless, as Mr. Fowler has produced a machine well adapted for stiff clay and loamy soils, and consequently for the very description of land the most oppressive to horses, and the most expensive to work, the judges consider that he has established a good claim, not only to the amount of the premium offered, but to whatever support and encouragement the Society's award can afford; and the judges would hope that this liberal interpretation of the terms in which the premium was offered, will operate as an inducement to others to persevere in their efforts to improve the machinery of the farm.

In conclusion, the judges have to express their acknowledgments to the Stirlingshire Agricultural Society for their arrangements; and to Mr. Forrester for the facilities and assistance he afforded in conducting the experiments, as well as for his great attention and hospitality.

—*Journal of Agriculture.*

THE PLOUGH, OR ITS SUBSTITUTE.

In the concluding portion of our last article we adverted to a point which has often occurred to practical men, namely, that the easy turning over of a regular slice of soil is not all that is desiderated in the action of the plough—that the whole work which we require it to do must be taken into account, and that lightness of draught must not be sacrified at the expence of the disintegration of the soil. It is evident that to scratch or score the surface with two horses must of necessity be done cheaper than obtaining deep culture by the use of eight horses. This refers to the mere doing of the work. But we must go into the question of results, if we wish in the end to ascertain which is the cheapest mode of operation. If where shallow culture is carried out the profits bear a higher ratio to the cost of working than where deep culture is adopted, then by all means adhere to shallow, and discard the deep. But so far as experience points out, the case is exactly the reverse, and everything, nearly, goes in favour of the deep culture. It is evident then, we think, that the mere lessening of the draught of the plough is not all we want, unless this lessening of draught is taken into consideration together with the peculiar state of the soil which experience points out as the best fitted for our purposes.

But supposing us to obtain a form of mouldboard that gives more disintegration of the soil, and requires less power to work it, than that of any plough yet introduced, we have still a difficulty to overcome, which we have shown to be attendant upon the action of every plough—namely, the formation of the hard crust formed by the passing of the sole of the plough over the soil. There can be no question that this is a serious evil. How to overcome it, is a problem occupying the attention of not a few of our agricultural mechanics. Rollers, on which the sole is to run, have been proposed; but although these will tend to mitigate the evil, they will by no means get rid of it. Revolving tines, like those of the Norwegian harrow, have also been suggested to follow immediately upon the action of the plough, and tear up the surface on which the sole has been resting. But in the attempt to combine two or more operations in one machine or implement there is always danger either of obtaining work partly done, or getting the work done, if it so happens that it is good, at a dearer rate than it could be performed by two machines or implements, each having its own task to perform. Our manufacturers know this, and almost invariably act upon it. They have their machines of preparation as we may term them, and their finishing machines; each machine, however complicated, doing its own work preparatory to that which is to succeed it. And in directing our attention to what has been done in agriculture, we find that the nobleman who has made his name famous in connection with indubitably successful deep culture, has followed the same principle. Thus, convinced of the advantages of a deeply pulverized soil, he has by dint of experimental research discovered a form of subsoil trench-plough, in which a peculiar and simple member acts upon the soil—*left untouched* by the plough of an ordinary principle of construction, but capable of taking a furrow of much greater depth than is ordinarily effected—so as to completely disintegrate it. But although this subsoil trench-plough, as it is called, follows immediately upon the action of the plough, the two implements are not combined in one, with eight horses working the combined implement; but each implement does its own work, having each its own complement of four horses. And this arrangement has doubtless been adopted after mature consideration, and from a conviction that the work would be cheaper and better done than with the use of a combined implement. But apart from this consideration—the utility or non-utility of the combination of two principles of action in one implement—the question forces itself upon our notice, What necessity is there for the plough, in both of those plans above noticed, forming part of the mechanism employed?

Grant that by the use of revolving tines following close upon the action, and forming part of the mechanism of the plough, we completely obviate the hard crust, and that by the use of the "subsoil trench plough," with, its peculiar member we obtain a pulverized soil to a depth of nineteen to twenty inches. Although in this latter case it will be seen that we still reach a limit beyond which the pulverization ceases, and the hard crust begins; and that, although a deep soil with a hard crust is better than a shallow one with the same obstruction, there is no reason why the depth should be *limited* to 20 inches any more than it should be carried out to six only, as some hold—granting so much, would it not be cheaper to employ mechanism that would at once give us a pulverized soil, the depth of which could be regulated at will, and at any point of which there would be no hard sole or crust similar to that formed by the plough? And which, in fact, is a practical limitation of the depth. Is it positively an essential to good cultivation, that the soil must *be laid over in regular slices*, and that the weeds, leaves, &c. *must be buried* under the surface? Spade husbandry is *said* by nearly all to be the most efficient; yet the spade does not lay the soil over, as the plough does; neither as a necessity of its mode of operation is *all* the surface matter buried by its use; and most assuredly it forms no hard crust, on which water may lodge, or through which the roots of plants may with difficulty penetrate. That it effectually turns over the soil, and leaves it in a condition fit for the action of the atmosphere, is admitted by all. A careful observer, uninfluenced by the force of habit or the trammels of preconceived notions, would be inclined therefore to ask, Why is not this system of cultivation carried out? And if met by the objection that from the dearness of manual labour the expense would practically be prohibitive of its adoption, the answer—in view of what mechanism has effected—would naturally occur to him that this was simply a question of economy, which could be solved by introducing some kind of mechanism, when the same cultural results could be obtained as by the use of the spade, and at a rate which would render the operation a paying one. But on pushing inquiries further, our observer would find unanimity of opinion in reference to the value of spade husbandry merely nominal. For while many *say* that it assuredly is the most effectual mode of cultivation, it is notorious that they act as if they did not believe it; and so far from there being an unanimity of opinion on the point, we find a great diversity, so far at least as the application of the spade to *farming purposes* is concerned; for it may to some appear strange that, while admitted to be available for gardening purposes, and productive of good results there, it is not so for the farm.

Before asking our agricultural mechanics, then, either to improve the present plough or to invent a substitute for it, it seems but fair that agriculturists should decide as to the peculiar state in which it is desired to have the soil—Whether ploughing, in short, is essential. Or whether simple disintegration is only required—the state in which the surface is left, or its peculiar finish, being a matter of trifling or of no importance. Let it be understood that a good implement *must* give two things—(1), a well-stirred soil, with a depth easily regulated—knowing no practical limit, so far as the action of the implement is concerned)—and (2), a laying over of the soil so stirred or moved at a determinate angle, forming a furrowed surface. Or, on the other hand, that that which is wanted from the implement is simply one thing—that it shall give us the soil well stirred and disintegrated, without reference to the way in which the surface is finished. Let the agriculturist say what he wants, and we have so much faith in the ability of our mechanicians as to believe that they will be able to introduce something that will supply the want. It is not fair to the mechanic, nor is it good policy on the part of the agriculturist, for the latter to throw on the shoulders of the former the double onus of ascertaining what has to be done, and how he is to do it. The best and quickest way of arriving at the solution of the difficulty will be to combine the knowledge of the farmer with the skill of the mechanic. Each aiding the other with the knowledge which long experience in their occupations has given, we may hope to see a machine or implement introduced which will, with no hesitation or doubt on the part of the farmer, be accepted as performing all that he requires.

The settlement of what is wanted is the first thing that must be done, if true progress is wished for. So long as we find two great parties—each holding opinions nearly, if not totally, irreconcilable—so long will we find that the efforts of our mechanicians will be frittered away. It is hard to believe that both opinions can be right. Grant that one is wrong, and it is evident that all the efforts of our mechanicians to meet its requirements must be simply lost time, and must incur a needless expenditure of money. Better far to decide on the way we have to go, and secure the aid of our mechanicians to help us on in our journey. We shall, at least, have the benefit of united effort. The points of the question to be decided present features of momentous interest to the nation at large. We are, if we read the signs of the times aright, on the verge of the extended use of a new power, which in other branches of our national economy has effected amazing wonders; and in view of this probable use of a new power, we are afforded a most fitting opportunity of inquiry as to whether the old implement of culture is adapted to it. We have many lessons given to us, in the history of the progress of other branches of our arts, to make us pause to give this inquiry full weight. In the early days of the power of steam, we find that it gave out its wondrous might through the clumsy medium of Newcomen's atmospheric engine; but the genius of Watt saw that it could only put forth all its majesty through the agency of mechanism adapted to *all* its peculiarities. When the ambition of a Symington or a Fulton prompted the application of steam to the propulsion of vessels, with the power of man they discarded his time-honoured implement the oar, and yoked the giant to the whirling paddle-wheel.

We have, at all events, arrived at a point affording full facilities to an exhaustive inquiry, as to whether the time-honoured plough is the fittest instrument of cultivation. No longer do we find those who uphold it as perfect. It has acknowledged defects, acknowledged even by those who maintain that it is, nevertheless, the best implement we can have. And if we find that any modification of its mechanism, by which these defects are obviated, brings about a condition of soil much resembling that effected by other implements not possessing the peculiar features of action of the plough, then the question will be brought nearer to that point where it narrows itself to one of comparative economy in working of different implements, no matter what their distinctive peculiarities may be. That the plough must be modified, to enable it to do the work demanded by a more comprehensive system of cultivation, is obvious enough; and that these modifications will tend to bring its operation nearer to that of implements or machines which by many are considered at present altogether heteredox in principle, not a few are inclined to think. Chief among the influences which will necessitate these modifications will be the power of steam

A PLAIN FARMER'S VIEWS OF THE NEW THINGS IN AGRICULTURE.

Hanson's Potato Digger, made by Coleman of Chelmsford.—This is the *newest* implement of note I have seen, and, I see, is called "the implement of the season." It consists of a frame of wood in shape something like the Ducie-drag frame, but longer, and is supported upon two large-sized and strong carriage wheels of wood, with a pair of small iron steerage-wheels in front, wide enough to bestride the potato ridge. These are attached to an upright stem formed as a circular rack, allowing the wheels to be swivelled, and also permits it to be raised or lowered by means of a pinion and winch, and fastened by a pin through the rack. Underneath the hind-part of the frame a strong bracket carries, by the share-stalk, a curved triangular share or cutting spade (a hodding spade) which passes in a nearly horizontal position under the potato-rows, raising up the whole mass for the freer operation of the revolving forks. These consist of a disc of eight two-tined arms or forks on a horizontal shaft, made to rotate transversely behind the machine: this shaft is actuated by means of two mitre wheels, one on the shaft and the other on the axle of the driving carriage wheels, both nicely covered or boxed in. These wheels set the whole in motion by reversing a cam placed in front of axle, and thus permitting the machine to travel when not in work. The wheels are armed with pegs of iron, in a wedge form, to prevent slipping in work. To allow the disc to be set higher or lower there is an adjustment behind for that purpose, and the forward end of the shaft works in a movcable socket bearing on the axle of the carriage wheels. The machine is cleverly contrived and does the manufacturer great credit. I objected to the size and coal-shoot form of the share: its very form causes it to clog in work, of course adding greatly to the draught. We see no reason for such an immense share for such a simple purpose. A common curved coulter with such a share-stalk would, I think, do better. The share is certainly a very clumsy one; and I hope, when I next see the machine in work, to find a great improvement in this particular. I think it a mistake to suppose it is requisite for the row to pass into this shoe or share, and from thence to be thrown abroad by the revolving forks: this is not necessary. The revolving forks work at such a speed that nothing more is required than simply to raise the row to ensure its being thrown abroad with great facility; the instant it is raised the forks seize it and all is instantly thrown out for convenient picking. I have repeatedly seen it at work, and such is its power that no trifling obstruction can interfere with its proper working. It cannot on all soils, as now arranged, be fairly worked by two horses; it mostly requires three, on stiff soils, to get forward with expedition. The whole row of potatoes, haulm, and soil are thrown out and scattered almost inconveniently far abroad; so that in some cases a screen to prevent this is attached to the side by an apparatus for that purpose. I worked one of these machines on my own farm, in the past season, and was much pleased with the result; for in addition to the dispersion of the potatoes by the forks, the soil itself received a good pulverization, and all roots and rubbish were thrown out on the surface; thus saving the cost of a subsequent harrowing and other labour. I do not hesitate to assert that, with some modification, it is a highly useful implement, and will come into general service.

Crank-axle Carts.—I will next make a remark or two upon this new feature in our carriage-department of agriculture. The Royal Agricultural Society offered a prize for the best cart with crank-axle, to be decided at the Salisbury Meeting. I took pleasure in examining the carts shown in competition; but for general-purpose carts I speedily descried they were inadmissible. The long shafts I approved, as giving the horse more power over the carriage. The high wheels (which the cranked axles were designed to accommodate) are undoubtedly advantageous in point of draught; but they appeared to me to be disadvantageous in other respects. The shelvings could not be prevented pressing on the wheels under a heavy burden. The usual height of a common cart-wheel is about 4½ feet. In these carts the diameter is six feet, and some even more. In loading, there must be inconvenience from the height of the sides, and in unloading, too; for take the tipping, the low cranked axle cannot permit the cart-body a sufficient incline to slip out the load behind, and the bottom is so low that over many of the roads in my neighbourhood they could not travel, in consequence of the depth of the ruts. The axle itself would slide on the surface. Then again, their large wheels would continually throw into the body of the cart such soil or mud as adhered to them, unless prevented by high shelving boards. The principal advantage that I could discover was that it is almost impossible to overturn them; the load is so low, resting almost between the wheels; and their light draught upon hard level roads—these are great advantages.

MOWING AND REAPING MACHINES.

Although this class of machines is not decidedly new, yet some of them have undergone such extensive and recent alterations as almost to constitute them new machines. It is with such that I have to do, and that very briefly. Perhaps I shall not be in great error if I consider and treat mowing machines as *new machines*.

Mowing Machines.—*Caryl's American Eagle Mowing Machine.*—The admirable way in which this machine cut the clover crop at Salisbury quite took me by surprise. I at once pronounced it to be the best of its kind hitherto produced, and the awards of the various prizes which have been conferred upon it since have fully borne out my impression. The machine is in most respects similar to our common reaping machines, both in frame and the position of the cutters; but in its more minute details it varies considerably. The most singular adjustment in it is its first moving or motive power. It is communicated from the axle of this most unique of all wheels. This wheel is made of cast-iron, is 3 ft. 7 in. diameter, and the rim is 11 in. broad. Throughout its periphery, and parting as it were what seems a solid cast-iron rim into two parts or slots, making a series of zig-zags or curves, which, alternately opening and closing, act as cams, and passing over or by a ball or roller attached to the cutter-bar, gives it that quick vibratory motion so requisite to cleanly cutting. The rapidity of the movement, and its singularity, is very striking, quite doing away with spur-wheels, cranks, or pinions to work the cutters. The whole is under the control of the workman, the frame being so nicely balanced that, by a movement of his foot, he can instantly raise or depress the knives, to prevent obstruction from a surface-drain or uneven ground. "The knives are acute, not serrated, and slide above fixed sharp fingers,

having thus a clipping or shearing action ; they are kept close and free from clogging by a spring pressure-bar, and each knife may be unscrewed off and renewed at pleasure. The length of the vibration is only 2 in., and the motion comparatively slow." The extreme length of cut is 5 feet. The machine is of simple construction, being small, compact, and light, and of easy draught; and when used as a mower there is not a cog-wheel in the machine. It is also adapted for reaping corn, by the addition of a curved platform; and a radial arm sweeps, by an ingenious arrangement, backward and forward over the platform, alternately lifting and letting fall a rake, which receives and delivers a bundle of corn at every $3\frac{1}{2}$ feet ; or the attendant can retain it longer upon the platform, according to the crop, at his pleasure. Its weight as a mower is about $6\frac{3}{4}$ cwt., as a reaper near 8 cwt. ; its width, 8 ft. 3 in.

I have not seen this machine at work as a reaper, and my impression is unfavourable as to its capabilities in that respect, from the manifest reluctance the managers show to give it a fair trial in a corn-field ; but as a mowing machine in moderate crops of grass or seeds it is beyond praise. The work done is so evenly cut, and so nicely distributed over the land, as to defy the competition of the best haymakers. In heavy crops of grass I observed the driving-wheel was occasionally clogged by accumulating grass or old fog around it, so as to prevent its turning ; this, however, was soon relieved by backing the machine. The knives, too, were occasionally obstructed by hard or woolley fog—i. e., last year's uncut decaying grass. This, however, will often stop the most expert "mow-men." I merely observe, that I entertain a high opinion of the efficiency and general usefulness of this machine, and believe it will ultimately obtain great public favour.

Dray and Co.'s Hussey's Mowing Machine.—*Mowing Machine as improved by Dray and Co.*—This machine, so far as my observation goes, is identical with their reaper, minus the tipping platform and facilities for the delivery of corn. This is all right. I like a convertible machine ; and this one certainly cuts grass and seed-crops in very good style indeed. It is somewhat smaller than the Eagle machine. The acute skeleton knives cut admirably. I have repeatedly seen this work both as a mower and reaper, and, although from its greater draught whilst taking less work, I cannot class it as equal with the Eagle machine ; yet it is certainly next to it as a mower, and the price is less, they being £35 and £26 respectively. It is well worthy encouragement.

Lord Kinnaird's McCormick's Mowing Machine.—This machine is, I think, very nearly identical with his reaper, being also minus the endless web and the other apparatus for the side-delivery of corn. I saw it mowing clover and grass at Salisbury ; the former it did very well, but the heavy grass crop and surface drains prevented a fair trial as a grass mower, which, in fair even work, it would cut very well. It is much larger, and takes a wider space than either of the above. The price low—£21. As a mowing machine, the breadth taken is against its cleanly working.

Mazier's Little French Machine.—I have seen this machine tried in both departments of mowing, neither of which it would effect with economy. It is a compact little thing, but for our go-a-head farmers it will never do ; they require a machine of greater capacity. It is also merely by being deprived of its many chains for side-delivery of corn, that it forms a mowing machine. It takes a limited breadth.

Reaping Machines.—In this department of manufacture we have a great increase, and many improvements. The first I shall name is *Burgess and Key's Reaper.* This machine is fitted with M'Cormick's well-known cutters. The great novelty is the addition of a newly-invented conical screw-divider. This is a large peculiar-shaped roller, like a pavior's rammer, which, revolving as it passes along, readily divides the upstanding corn, and lifts up the lodged for cutting. This is a decided improvement upon the divider-board, which tears its way through the crop, pulling up some and breaking off others, by which portions of the crop are lost. The gradually insinuating screw separates the corn without difficulty, and with less labour to the horses ; and scarcely any is dropped. The screw-roller delivery-platform is much as I have heretofore seen it, but I thought the width taken rather larger than past years—*i. e.*, 5 ft. 6 in. ; but the labour to which the horses are put is not excessive.

Crosskill's Bell's Reaper.—This reaper has undergone several improvements. It is the most useful and convertible of all the reapers. The propulsion being from behind, it can charge into the crop at any point. The cutting-bars immediately precede the horses, thus dispensing with the side draught. The endless web is so contrived that it can lay the corn in a continuous swathe on either side of the machine, thus opening a way for it to pass up and down the field at all times close to its work. It takes a breadth of 6 ft. 9 in., which is very great ; indeed so great, that two horses cannot readily work it. The machine itself, although reduced in size, is still too large and heavy.

Dray and Co.'s "Hussey."—This machine has not undergone any material improvement during the past year, except its convertibility into a mowing machine. The tipping platform is a decided improvement, but it is not a very recent invention. The delivery is behind, which is a great hindrance in work, as the corn must be gathered before it can take a fresh bout. It is the most compact and lightest reaper we have, and cuts admirably.

Palmer's Union Reaper.—I have frequently seen this machine in work ; all is done in a truly business-like manner. The large curved platform has a singular appearance, and is provided with rollers to assist the rake-man to effect a good side delivery. I did not observe anything essentially new this season, and to which I am trying to confine myself.

Lord Kinnaird's Reaper.—This is the cheapest I have seen, and works well. It would be rather more attractive if improved in its manufacture. His lordship has studied economy to a fault.

Wray's Reaper.—This is a one-horse machine, and came out for competition at the York meeting. It is similar in form to "Hussey's Machine," and has also a similar back delivery. The novelty to be noticed in this machine is the ingenious arrangement of its cutters, or rather in its series of knives. These consist of an endless band or series of cutting edges, in fact an endless knife, which in passing very rapidly across in front, and revolving freely from beneath the frame, cuts its way in a very business-like manner. The band revolves by means of two horizontal wheels, one on each side of the frame. In work, it appeared necessary that the pace should be quick, otherwise it did not cut well, and symptoms of clogging were manifest; and this clogging was a serious obstruction, as it was not readily relieved. I saw it tried thrice at York ; and although the pace was severe, yet the draught in cutting a breadth of 3 ft. 6 in. was not very great for the *one horse*. Undoubtedly the endless knife contributed much to lessen the draught, of course, there being less friction than from the vibrating motion of other machines. I was pleased with the machine and its working as a whole, and believe it to

possess many points of great usefulness. I wish it every success. The price, £30, is rather high.

MANUFACTURED CATTLE FOOD, *i. e.*, THORLEY'S FOOD FOR CATTLE — BRADLEY'S FOOD FOR CATTLE.

The manufacture of food for cattle is certainly by no means *new;* but as we find our agricultural papers teeming with advertisements of "Food for Cattle," I am tempted to look a little into the matter. I do not pretend to inquire into the mysteries of the food prepared by *Joseph Thorley, Esq.*, or Mr. Bradley, and others; but as these preparations of food are obtaining considerable notoriety, if not popularity, I may be pardoned for classing them amongst the new things in agriculture, and briefly alluding to them as such.

The great and very important subject which is here involved is that of *animal nutrition*. Now as this is a subject upon which I am free to confess great ignorance, I hope to be excused making copious extracts from a work now before me, and which ought to be in the hands of every intelligent farmer—"Morton's Cyclopædia of Agriculture." The article written by Professor Voelcker is a very talented and instructive one. He says—

No scientific investigation in which the animal physiologist engages is more intimately connected with the successful practice of farming than the inquiry into the processes of nutrition. On the views we entertain with regard to the theory of nutrition not only depends our success in breeding and rearing stock and the fattening of animals, but also the economic management and application of farm-yard manure. The greatest interest and highest practical importance, therefore, belong to the beautiful researches with which Mulder, Boussingault, Dumas, and particularly Liebig, have made us acquainted. We are bound to acknowledge with gratitude the services already rendered by these and other philosophers, who have endeavoured to determine experimentally the relative value of the different articles of food, and to throw light on the still mysterious process of nutrition. The bodies of animals consist principally of the following parts, the composition of which we must briefly consider: The flesh, or muscles; the blood; the fat; the skin, hair, or wool.

The fleshy parts, or muscles, of animals consist principally of muscular fibre, and contain, besides, cellular tissue, nervous substance, blood and lymphatic vessels, and an acid juice. In this juice is found a peculiar organic base, called kreotine, also lactic and inosinic acid, albumen, the sapid or taste-giving ingredients of flesh, and inorganic matter, principally salts of potash and phosphates of lime and magnesia.

Chemically considered, animal bodies may thus be represented as consisting of—

1st. Organic matters free from nitrogen (fat).
2nd. Organic substances rich in nitrogen (fibrin, albumen, &c.).
3rd. Inorganic salts (chloride of sodium, phosphate of lime, salts of potash).
4th. Water.

These constituents the animal can only have derived from the food with which it is fed, or from the air, in which a portion at least of the organic elements occur; but as we all know that life is not supported by air, the food naturally is regarded as the source from which the constituent parts of the animal body are derived.

Professor Playfair, in another part of this valuable work on diet, says—

All food may be divided into three groups:—
1st. Flesh-forming substances.
2nd. Heat-giving ingredients.
3rd. Mineral matter for the production of bones and inorganic ingredients of flesh and blood.

These three groups exist in all kinds of vegetable food adapted for the nutrition of animals. It is therefore easy to tabulate the principal substances used for human nutrition, so as to show their relative value.

Apart of which I extract, as showing the composition 100 parts o food as it occurs in commerce—

CONSTITUENTS OF THE PRINCIPAL SUBSTANCES USED FOR HUMAN NUTRITION.

Name of food.	Flesh-forming matter.	Heat-giving matter.	Mineral matter.	Carbon.
Wheat flour ..	17·00	66·00	0·70	45·50
Buckwheat	8·38	74·03	2·20	37·61
Barley meal ..	14·00	68·50	2·00	40·50
Oatmeal	13·60	70·30	3·30	44·10
Indian meal ...	10·71	75·25	1·04	36·41
Rye.....	13·83	71·43	1·74	38·27
Rice.....	5·43	84·65	0·52	36·00
Peas.....	23·40	60·00	2·50	35·70
Beans	23·00	58·50	3·40	33·24
Lentils	25·00	58·76	2·24	37·28
Potatoes	1·41	22·10	1·00	12·20
Carrots	1·46	11·61	0·81	5·40
Turnips	1·64	10·00	0·62	5·20
Parsnips	2·10	17·70	0·80	8·63
Mangel-wurzel	1·60	12·26	1·14	5·50
Cabbage	1·75	4·05	2·20	2·65
Cocoa-nuts	9·56	85·76	2·70	68·56
Sugar	0·00	100·00	0·00	42·58
Beer	0·85	9·17	0·20	4·33

The column exhibiting the amount of flesh-forming principles in the food is a very close approximation to the true nutritive value.

I have taken these extracts with the view of showing that in the hands of a good practical chemist a preparation or compound of ingredients made from the above articles of food named, and other sources, may constitute one of our most valuable resources for the fattening of cattle and the nutrition of other animals. I am generous enough to give Messrs. Thorley, Bradley, and others, credit for making the attempt to provide for this *want* in our new order of things. I regret that just at this moment I cannot lay my hand upon any analysis of the locust or Carib bean, which is so generally well spoken of, as adding nutritive value to many compounds. I presume these manufacturers of cattle food well know its value; for if one might judge from olfactory examination, it forms no inconsiderable portion of their mixtures. I find no fault with their prepared or "invented" food, their "invaluable compound" "invented by the sole proprietor," &c.: I believe them to be good and serviceable; all I desire is to guard my brother-farmers against "paying too much for their whistle." Thorley's Food is sold in cases containing 448 packages, each package one feed, at a cost of 56s. per case, or the same quantity in casks at 50s. Bradley sells his horse and cattle food at 42s. per cwt., and his pig food at 24s. per cwt. Mr. Thorley does not give us the weight of his packages. I am now purchasing barley-meal at 10s. 6d. per cwt., the best linseed-cake at 10s. 6d. per cwt., and Carib beans at 8s. 6d. per cwt. These are really great contrasts in price; but of course I do not compare their relative values with *these new things in agriculture;* in fact I know nothing about them, more particularly as to their composition. Those samples coming under my examination appeared to consist of a rather coarse flour of a yellowish colour, having the peculiar rancid smell of the Carib bean alluded to above. I have no doubt whatever that a judicious admixture of Indian corn-meal (maize), barley, bean, pea, or oat meals, together with Carib bean or linseed-meal, and similar substances, does constitute a good article of food, of highly nutritious and fattening quality. My aim in forwarding this paper will be fully answered if it should lead any of your readers to make full inquiry as to th nature of these kinds of food, and their value, befor making their purchases.

MILK.

[TRANSLATED FROM THE FRENCH.]

ORDINARY MILK—THE MILK OF SPAYED COWS.

Notwithstanding the important place milk occupies as an article of diet, nothing is more common than milk of poor quality. The conditions under which milk is produced explain the rareness of good milk.

If we examine the milk of a certain number of cows in the country, we find united, 1st, the milk of cows that calved ten, fifteen, twenty, or thirty days previous (*). 2nd. The milk of cows in heat, and essentially prejudicial to health. 3rd. The milk of cows with calf (†). 4th, and as an exception. A small quantity of good milk—that is, milk from cows that have calved five or six weeks previous, and which are neither in heat nor in a state of gestation. It is therefore seen that milk is in most part of mediocre quality, or of a nature unfavourable in respect to hygiene: and yet this milk, furnished by farmers, surpasses by far the milk from cows kept in stables in the city.

The condition under which cows in city stables are kept produces another cause, grave, serious, which greatly adds to the poor quality of milk above designated—we mean pulmonary consumption, by which a large number of cows are attacked. Has it not been stated, in fact, by veterinary physicians, that one-half at least of the cows kept in stables in Paris are phthisical?

Is it not evident that such milk is not only deprived of its nutritive qualities, but is very injurious to health? and the water, which in the retail is added to this milk, assuredly does not redeem the original vices.

In regard to the alterations in milk arising from the manner in which the cows producing it are kept, it is difficult to estimate them, otherwise than by their taste. As to milk diluted with water, consumers can easily prove this fraud. A first means consists in the employment of a small instrument, simple and of small cost, called galactometer or milk weigher. Plunged into the milk, it indicates exactly, by its divisions, the quantity of water which has been added, whether a quarter, or a third, or a half; for it is not rare that milk is diluted in the latter proportion! Or a certain quantity of milk may be left, to remain for six or eight hours, in a cylindrical glass vase called a gauge, or in an ordinary glass: after this lapse of time, the cream which has risen to the surface, and which is distinguished by its colour, reveals by its thickness, and still more by the resistance it presents on touching it, the butter quality of the milk, that is, its richness in the principles proper for the extraction of butter.

In the establishment we have founded in Paris under the name of "*Dock modele de la vie a bon marche* (‡)," the trade in milk has extended considerably. Although the *Dock* delivers to consumers milk which is obtained from the country only, and rejects the milk which *turns* in the operation of boiling, it is often complained that the milk bought of the *Dock* has turned. We will take this opportunity to observe, that the best and purest milk will turn under the influence of a change of temperature, improper care, and the employment of an improper pan or vase, etc. (§); that the administration of the *Dock* might prevent the decomposition, accidental moreover, of its milk by adding water, or the bicarbonate of soda; but this establishment, limiting itself to selling pure milk, leaves it to the consumer to add these articles.

As it is in bad spirit to indicate an evil without pointing out the remedy; and, having proved the poor and often bad qualities of ordinary milk, we are happy to speak of milk of an excellent quality, which is yet unknown to consumers, and of which the *Dock modele de la vie a bon marche* has the honour of popularizing the use.

THE MILK OF SPAYED COWS.

This milk is produced from cows which, after the fifth or sixth gestation, and five or six weeks after calving, undergo an operation which consists in the ablation of the ovaries, thus rendering the cows henceforth incapable of reproduction (*). From this time, as happens in regard to the ox, the animal changes in nature, and its milk, which we have named milk of spayed (*lait de beuvonnes*), is free from all perturbations. The spayed cow does not undergo those disturbances arising from being in heat, from gestation, and parturition; she is free from those causes which produce such evil effects in the quality of milk.

In this new condition of the cow her milk becomes regulated, and—which is important to the farmer—lactation is maintained in full quantity for a year at least, and is prolonged, diminishing in quantity but increasing in quality, two and even three years, when she is not too old and is properly kept. When lactation has ceased, the cow, which has, by a quiet and reposed life, become considerably increased in flesh, may be delivered to the butcher in perfect condition, and the meat is superior to that of ordinary cows. By generalizing the spaying of cows after the fifth or sixth gestation, there would be introduced into common use milk of an irreproachable quality.

The milk of spayed cows gives more cream than ordinary milk; it is also richer in casein, which constitutes—a fact generally unknown—the most nourishing part of milk. Hence the superior quality of the milk. The butter extracted directly from the milk is delicious in taste: it testifies to the amount and richness of the casein it contains. This milk offers precious resources for the artificial nursing of infants: it might be asserted that they will be better nourished; for the nourishment of infants, who give it the preference over other milk (†), we do not doubt that the milk of spayed cows will be principally used.

Such is the milk which the *Dock de la vie a bon marche* now introduces for consumption.

This milk, the production of which for a long time yet will be far from meeting the wants of those who appreciate its excellent qualities, sells for a higher price than ordinary milk; for it is necessary to pay a higher price to the farmer either to overcome, by the advantage offered them, the resistance which routine always opposes to the best discoveries, or to compensate for the risk of mortality which the cow undergoes in the operation of spaying.

If, as we doubt not, the milk of spayed cows takes the place in domestic economy it should occupy, the *Dock* is assured of satisfying gradually the exigencies of the consumption, by the numerous operations it is causing to be made from the present time.

DELAMARRE,
Proprietor of the Dock modele de la vie a bon marche.

* It is known that cows' milk is not good for domestic use till a month or five weeks after calving; and it is well known that farmers put away their calves eight or ten days after birth.

† This milk generally predominates, as it is common to milk into the sixth and even into the seventh month of gestation.

‡ Rue de Croissant, No. 44, Paris.

§ One precaution we would recommend; that is, to avoid placing the milk over a blazing fire, but to submit it to the action of a mild fire.

* The spaying of cows was known in remote antiquity. In modern times the practice of this operation, with the design of increasing the quality of the milk of cows, dates back but about twenty-five years. It was applied with advantage in the production of milk in 1830, by Mr. Winn, of Natchez, Mississippi, U. S.; but Mr. Winn and his successors proceeded by the cesarian operation, which presented serious difficulties, and was often followed by the death of the animal. At the present time, by a proceeding recently discovered, a skilful veterinary surgeon, M. Charlier, executes this operation without an external incision, and renders the chances of mortality much less.

† All persons who are in the habit of tasting milk, readily recognize the milk of spayed cows by its more unctuous and sweeter taste.

STALL FEEDING OF CATTLE.

The recent discussions in the Farmers' Club House in London on the subject of farm buildings, and more especially of the parts that are destined to accommodate the fattening of cattle, having terminated in no special adoption or recommendation on that point, I am induced to make a few observations on the subject, as it is a part of arrangement of a very chief importance in the designing of improved farmeries. I have ever been of opinion that open yards with shelter sheds form the best accommodation for fatting animals, and I perceive that Mr. Baker, of Writtle, is of the same opinion, after all that has been spoken and written on the subject. I am pleased with Mr. Baker's judgment, as his authority weighs heavily on all points of enlightened agriculture. It is impossible to see what advantage an animal confined in a box or single stall can enjoy over two, three, or four together in an open yard provided with a shelter shed, racks for straw, and cribs for roots. I remember having seen, nearly thirty years ago, a feeding shed with single boxes, on the farm of Wark, near Coldstream, on the English side of the Tweed, which was designed and used by the celebrated Culleys, who for a long time flourished on that farm. The turnips were given to the animal through a spout-hole in the front wall, and the space barely allowed the beast to turn round, who could enjoy no exercise. The position was dull, cold, and uncomfortable, and the plan never advanced into use, and was not approved even on the farm where it was seen.

Two of the largest-sized animals of any breed are most beneficially provided in an open yard with a shelter shed, and three or four of the medium-sized will do equally well in that accommodation. The aspect of the yards must front the southern hemisphere, and be shone upon by the sun during some hours of the day. When filled with meat, the beasts lie down and bask in the yard in fine weather; and during rains and storms, retire into the shed, and repose undisturbed and under shelter. In wet and stormy countries, it will be advantageous that the animals eat under cover of the shed, and for this purpose it is contrived that a railway runs along the wall of the sheds, and discharges the turnips through spout-holes in the wall into the cribs placed in the shed; but in most cases the roots are placed in cribs with latticed bottoms, and the straw in an open rack.

Two, three, or four beasts of any size are most conveniently fattened in this way; but with Scotch cattle a different arrangement is required. The larger breeds may be treated as English cattle; but the small beasts, called Kyloe or the West Highland cattle, of which there are several varieties, are so very restless in temper and pugnacious in disposition, that the tying system in stalls becomes eligible, and even imperatively necessary. These animals require to be wintered for two years—the first, they may run in an open yard and shed in six, eight, or ten together, and be half fattened on untopped turnips and straws in racks; the second, the beasts are tied to stalls in double trevises, and are fully fed with topped turnips, beginning in November, and will be finished in March and April. The very small Highland cattle may be fattened in yards, but the Argyle and Dunrobie breeds require to be tied in stalls. And with this view every feeding farm should be provided with a fattening shed along with the open yards for the purpose.

A yard, including the shed, of 60, 70, or 80 feet long and 30 wide, will accommodate 2, 3, or 4 beasts, as it may be built. The shed is 20 feet wide, and has a square front opening of 12 feet. The bottom slopes outwards, in order to provide a dry bed, by discharging all moisture to the yard; the roof is filled with loose straw from the level of the walls to the top ridge, supported by beams apart at the necessary distances. This filling prevents the cold of the otherwise empty space; and the openings of the loose straw allows the passage of air, without the close confinement of a ceiled roof. The bottom of the yards slopes to the gateway in the interior of the farmery, to which the urine falls, and escapes in an open gutter to the south front of the farmery, where, being received by an iron grate into a covered drain, it is conveyed to a tank, and absorbed by earths, or prepared as liquid manure. But the strawy litter of the yards will in most cases absorb all the urinary fæces; and, after all that has been said and written on the subject of liquid manure, the best use of it is in that way. I have for many years advocated the cutting into short lengths of all straws used for litter; that the yards be thinly and frequently strewn with the cut straw; and that mixed excrements be all lifted and carried in a fresh condition to the prepared land for turnips, be covered in broadcast by one ploughing, and subsequently mixed with the soil by the workings of Finlayson's harrow lengthwise and crosswise. Fresh dung is superior in effect to the mixen of fermented heaps: the specific caloric, or animal heat, of freshly voided fæces is much more efficacious than the production of artificial fermentation. Whatever the cause may be, the fact is certain.

The proposed design of roofing over the entire farmery, like the terminus of a railway, may not be eligible for the purposes of agriculture. The exclusion of the rays of the sun will render the whole area cold and ungenial; and it seems necessary that the warmth of that luminary be applied to all objects of organized life. An open yard, for necessary heat and occasional exercise, with a shed, to which to retire for shelter from rains and storms, appears to be the best arrangement that has yet occurred.

The very superior quality of the turnips and the straws over Scotland and the North of England fattens into prime beef the cattle of these countries, and no variety of food is ever proposed. In South Britain other kinds of food are used, which require boxes to be placed in the yards or sheds, from which the beasts can eat the meat. The shed may afford a cover for that purpose.

The piggery and poultry yards are best in being wholly disjoined from the farmery, and placed on some side of it, or in the south front, as the walls are low, and the buildings will not exclude the sun from the yards that are behind. An excellent yard for store pigs may adjoin the stable, where the strawy litter, with hot fæces of the horse, affords a most agreeable bed to the swine; and a valuable manure is compounded with the cold and saponaceous excrements of the pig with the dry and hot fæces of the horse. The winter food may be roots and raw potatoes; and during summer, clovers and vetches. The animals will be in good readiness to be transferred to the feeding-sties of the piggery, wherein, two together, the fattening process is finished for bacon.

J. D.

THE SMITHFIELD CLUB CATTLE SHOW.

DEAR SIR,—The stimulus given to the agriculture of this country by the efforts of the various societies of the kingdom, and amongst them *especially* those of the Smithfield Club, is by no means alone displayed in improvements in the breeds of cattle, sheep, and pigs, wonderful as this has been the last few years. I may go further, and say, that in the invention and improvement of agricultural machinery, and in the application of new mechanical powers (if steam and railroads can be called mechanical) to the processes of agriculture, the progress made has not only kept pace with, but has far outstripped, during the last ten or fifteen years, *that* made in the breeding and fattening of animals for the slaughterhouse. In some respects, I cannot see any great improvement upon the efforts of Bakewell and the Collins', who by dint of that discernment, united to a confidence in their own judgment, which few amongst us are fortunate enough to possess, arrived at perfection, or nearly so, by what may be truly called "a royal road," and produced cattle and sheep quite equal, in point of symmetry, compactness, quality of flesh, and smallness of bone, to those of the present day. The chief improvement I discover is in that wonderful precocity which distinguishes the several kinds and breeds of animals, and which, however advantageous to the grazier and breeder—and I may add, in some respects, to the public in general, by affording a larger supply of meat—it is still a question whether the *quality* of precocious beef or mutton is equal to that which has had a reasonable time to arrive at maturity. Certain it is that our neighbours the French are glorifying themselves on the superiority of their beef, to that which John Bull himself can now boast.* It is true, I don't give them *all* the credit they thus claim; for although I have never been across the channel to eat "*ros-bif*" in that country; as an old farmer and grazier I can form some judgment of what sort of "*bif*" it must be, that is furnished by a five-year-old bullock, who during at least three of those years has been employed in doing all the dirty work of the farm, to the hardening of his muscle and the impoverishment of the mucous-membrane and the juices of the body. This is not the question raised; but whether a bullock of four or five years old, who has lived a *gentleman's life*† *the whole time*, does not furnish better and more savoury meat than one of two years, at which age so many are now killed? The same reasoning applies to sheep as well as bullocks, and has much truth in it; but we must still consider the modern system of breeding and grazing a vast improvement. By it we raise a weight of meat in two years as great as was formerly done in four, so that the quantity brought to market is doubled, and the increasing demand met, without a *proportionate* increase in the number of animals.

In respect, however, to the advance made in agricultural machinery, there can be but one opinion—that it has been rapid and beneficial. The exhibition at Baker-street was calculated to strike a stranger with astonishment at the wonderfully inventive powers of man in the construction and perfection of the steam-engine and its application to the various operations of the farm. The "reaper," too, with Burgess and Key's addition of the Archimedean screw, which so greatly facilitates the binding of the sheaves, is an extraordinary effort of genius; and Boydell's steam-plough and traction-engine is the crowning application of the monter-power;* and whatever room there may be for improvement in its construction, the principle of steam-ploughing is beyond a doubt established, and its adoption on large farms at no distant day is certain. These two machines, the American reaper and the steam-plough, may be considered the most important additions to the furniture of a farm, as facilitating and shortening the time of labour at those periods when time is of so much value to the farmer. The plough will also liberate the horses of the farm, to be employed upon other work, without interfering with the tillage.

In passing through the machinery department of the Show, a person who, like myself, can look back to the state of the farmer's stock of implements at the commencement of the present century, cannot but compare the lightness of the labour of the farm now with the onerous toil of that period. It is not saying too much, I think, to assert that one-third more work can be done now with the same number of hands, and that the land therefore receives one-third more tillage than formerly, in the course of the year. This will undoubtedly increase the produce, as well as place the labourer in a better condition by superseding the heavier work performed heretofore by hand. If this extended only to the two departments of the flail and the sickle, it would have conferred a large boon upon the labourer; for I can testify, from experience, that nothing tried the strength of a man more than the barn-labour and reaping; although the latter, from its short duration, and the good living incident to harvest time, was less permanently wasteful of the labourer's strength than thrashing.

But the lightening of labour is not confined to these two departments. Every *old* implement used upon the farm has been so improved as to render the use of it less laborious; whilst innumerable *new* ones have been invented, all tending to the same result of economizing the strength of the operator, or of superseding it altogether by the application of machinery. I might refer to the chaff-cutters, the corn-dressers and screeners, the root-cutters and raspers, the haymaking-machines, with numerous others, by which the work of the farm is performed with so much less of manual labour, and in less time than formerly. The effect of this will be sensibly felt in a few years; not only in the greater produce of the land, but in extending the average period of the labourer's efficiency, and rendering his old age less painful and burthensome to himself, and to society less useless.

It is very evident that the implement department is becoming too large for the place of exhibition. As to taking a systematic and critical survey, or even a cursory examination of the various machines exhibited, there

* See the "Journal d'Agriculture Pratique," of Nov. 5, 1857.

† A negro in the West Indies was asked to define the word "gentleman." "I s'pose," said he, "dat de pig is de ony gentleman." "How so, Sambo?" "Why, you see, massa work, missie work, oberseer work, horse work, nigger work; all work but de pig—derefore de pig is de only gentleman."

* It is a singular coincidence that a friend of mine, connected with the Board of Public Works, in Dublin, suggested, *six years ago*, to an engineer, the very plan that Boydell has carried into effect. The engineer doubted whether the shoes would not fly off when the machine was in motion, and my friend thought no more of the matter. This, however, does not affect Boydell's claim to originality, as he knew nothing of the affair.

was not room for it, even if the place had been clear of visitors. But, with such a crowd as attended on the two days I was there, it was impossible to examine any one machine so as to form any competent judgment of its efficiency; and I gave up the task in perfect despair, and could only walk through the rooms and admire the perfection of the workmanship of the several machines, and *guess* at their adaptation to the work for which they are designed. This is the only fault attached to the Show, but it is a great and *growing* one; for every year adds to the number of the specimens exhibited, whilst the bulkiness of many of them requires a much larger space to display their capabilities.

Whether the present site of the Exhibition is the best adapted to the purpose that can be obtained, is a question I do not feel competent to decide; but there is a plot of ground in the centre of the metropolis which might be devoted to that purpose, if it is attainable. I refer to Old Smithfield, where an ample building might be erected suitable to the Show, and applicable to other uses during the rest of the year. I understand that a portion of the ground is to be appropriated to a dead meat market, but there would still be abundance of room for a *Smithfield Club "Crystal Palace."* Such a building would reflect honour upon the Club, and I think might be managed so as to yield an ample return for the capital expended.

Yours truly,

AN OLD NORFOLK FARMER.

London, Dec. 15, 1857.

FEEDING OF CATTLE.

I felt happy in seeing the question mooted in your paper of the 9th instant, "What shall we do with our sprouted wheat?" It is one which I am very certain has been too much neglected since the disastrous harvest of 1856, when so much of that valuable cereal was rendered unfit for the usual appliance to human food. Having used grains, especially oats and barley, for several years in the finishing-off my fattening cattle, generally using this artificial food three months before selling, and always found its use profitable; even when cattle were as low as 8s. a Dutch stone, I considered it a profit to use these grains, when oats were under 20s., and barley 24s. per quarter, for the respective standard weights of 40 lbs. and 53 lbs. per bushel. I have often remonstrated with my agricultural friends on the folly of using oilcake at £11 and £12 per ton, when grain was at these rates, especially when in most seasons from late districts they can both be purchased at light weights, say 36 lbs. and 48 lbs., thus reducing the price. While I draw attention to these inferior qualities, I may state that I never found it a loss to use the very best quality of both, as when good I got it cut with mill stones, without drying, and thus lost no weight. Having a corn mill of my own, I doubtless possess a facility for stuffs to mix the cut grains with, which others, differently situated, may not so easily obtain; but this is very secondary, as I conceive cut straw, chaff, and husks of oats got from a corn mill quite suitable: better than either, bran would suit the practice admirably. My own practice has been to give either meal seeds, which sell at 5d. a stone, or corn dust, which can be had at 4d. a stone. The meal seeds, being sweeter, is taken with more avidity; but when once cattle commence with them, I find no difficulty in getting them to take dust when given instead. Just now, my milch cows are all getting cut wheat, with dust, while the fattening cattle are upon the seeds. The immense importance of such a feed over oilcake is, that you save so many turnips. When feeding off cattle in the early spring months, I have given as few as one-fourth the quantity of turnips an ox would eat, when not supplemented; in such a case, giving water once a day. I may briefly state my own mode of treating the cattle. When they are put up in October they get for two weeks turnips alone, fed thrice a day; after such time I give one feed of cut grain, either oats, barley, wheat, or rye. I have frequently used Irish meal, when it could be bought not over 30s. a load. The quantity of cut grain allowed at first, 3 lbs. a feed, mixed with nearly a stable pailful of meal-seeds or corn-dust. The cost of such feed at present, taking wheat, rye, or barley at 30s., will not exceed 4½d., and, I may mention that cattle thus fed will do as much in three weeks as in a month if on turnips alone. I always give it dry; at first it was made into brose, but I find the cattle take it more readily dry, and it seems to do equally well, if not better, with them: let it be understood, this food serves wholly for the usual supply of turnips at this time of feeding. When scarce of turnips I give the grain feed twice, and turnips once, thus saving two-thirds turnips; and if having sufficient straw for littering and eating, I can feed three cattle for one; and I am very certain that when I raise the grain-feed to 3½ lbs., and give twice a day, and once turnips, I can fatten twice as fast as on turnips alone. My stalls for the food are flag stones, so no trough is required to give the food in; the cattle-man just sweeps it clean with a wisp of straw, and when thus occupied, never have you seen horses more restive for their oats when hearing the corn-chest opened, than the cattle for this their dainty food. I have all my milch cows just now in a flow of milk on the same rations. In their case I give the corn-dust instead of the meal-seeds; it is cheaper and more plentiful. I consider if a cow is giving 8 quarts, it is profitable to feed her thus, either once or twice on grain, as you may deem fit. You will secure 11 or 12 quarts instead, have the butter sweet and free of turnip taste, and, on a cold frosty morning, have the satisfaction in seeing your cows eating with comfort, instead of trembling over a mass of frosty turnips. When cows are becoming dry, or when the flow of milk gets below the said minimum quantity, it is the better way not to force, unless the cow be not in calf; in that case feed on as high as you please, for cows milk to the last and lay on very fine beef too. Your correspondent "S." refers to analyses of cereal grains in Professor Johnston's *Elements of Agricultural Chemistry*. I had my attention drawn to the very pages he notices from seeing the sprouted wheat selling at so low a price, as well as good rye; the rye is not priced by your correspondent, but it will be found to possess feeding properties in its analysis just about equal to wheat. Since seeing this, I have been using in the very same way rye and sprouted wheat in equal parts, in the exact mode as I have detailed. For two months my cattle feeding and milk cows have been thus treated, and my cattle-man says it is suiting better than the oats or barley, and the dairymaid has no complaints of a lessened supply of milk. Now, at the ruinously low rates of wheat (some of last year's crop I bought as low as 24s., it weighing only 53 lbs., and rye at present is only 22s. to 23s. per 53lbs. weight), I maintain it is madness to sell a bushel, and use turnips even at the moderate rate of 6s. a ton. In my experiments I have never taken into account the increased value of manure, which is very great when the byres are cleaned out from cattle so fed; the discharge of urine is found less by one-half, and the pungency of the atmosphere clearly proves the great increase of ammonia. Apart from this profit I am certain that if beef does not fall below 6d. a pound to the farmer, in selling his fat cattle, it is his profit to use oats, if not above 20s. per qr., at per bush. of 40 lbs., barley 26s. 53 lbs., wheat 36s. 62 lbs., rye 28s. 56 lbs., *rather than give full turnips* at 6s. per ton, and I question if many turnips this season are being consumed at so low a figure. Last season, when wheat was very wet, I had it kiln-dried before being cut; as unless so, it would have got musty, unless cut very frequently. I may mention a caution very much needed, however, in feeding with oats or oatmeal; the oats possess an alkaline character different from the other grains, and the cattle fed on them are very liable to get hoven, so much so, that I could never leave them for two hours after being fed with turnips, the first feed subsequent to the grain feed. When feeding with the oats, I had almost daily to use turpentine to suppress hoven, which is a

decided objection to using them at least oftener than once a day, in order to have the stomach clear as possible of the oats; my system being, to give them the last feed in the afternoon, and then no turnips till next morning. This I proved obviated the danger very much; still not altogether. It affords me great pleasure, however, to state, *with confidence*, that there is not the slightest fear of this hoven from feeding with the wheat and rye, or either alone. There is a further recommendation of the wheat I may mention—the cattle seem to prefer it to anything else—I mean any other grains; and I feel quite satisfied your correspondent is right when adverting to the improved condition of the wheat for feeding by being sprouted. In conclusion, it must be patent to every one who has tried it that the saving in turnips by using oilcake at *a cost of 4d. to 5d. a feed* is trifling, while in issuing the grain it is immense. By using one feed of grain, you not only get the value of the nutriment it contains, but by retaining the turnips longer under the absorbent action of the intestines you extract more nutriment from them than when using them alone. I have never tried the grain for young cattle, but am satisfied it would suit well, and be preferable, because less expensive than the oilcake you often wisely recommend, instead of full allowance of turnips to young cattle. In conclusion, I will add my own experience on hoven. To any who may try oats or oatmeal, and be damaged by the swelling, give two or more glassfuls of turpentine, in a half-bottle of linseed oil, taking care to shake the whole well together. This, if given early, is quite a specific. This dose is sufficient for an animal of 50 imperial stones. This subject I have once and again, for two years past, desired, through your paper, to lay before my agricultural brethren; perhaps I had not yet given my experience but for the article of your correspondent "S." of the 9th instant. Whatever value may attach to my experience, in making damaged grain of more value to many who unfortunately possess it, I shall feel very thankful for that. I by no means restrict its use to damaged grain, but to any, the soundest of it, ranging within those limits I have specified, and beef worth 7s. per imperial stone. My remarks, I feel, have lengthened out on my hand far beyond anticipation. I only fear they are too lengthy for insertion.

WILLIAM JOHNSTON.

Mill of Kincardine, 10*th Dec.*, 1857.

P.S—From what I have said above, those conversant with fattening cattle will not need to be told that beef thus fed not only is esteemed highly by butchers, but they will actually, if they know, buy them higher, the internal fat being much more plenty.—*North British Agriculturist.*

SURVEYORS OF HIGHWAYS, AND THEIR RESPONSIBILITIES.

Our readers are probably well nigh tired of what is called the "Broughton Astley Surveyor's Case," a further development of which is recorded in our columns this week; but we must ask them to bear with us yet again for a little while. The questions involved in the case are of the highest importance; and as the subject will have next session to be discussed in parliament, the case before us in all probability serving for a text, we are desirous that the public should be fully informed upon its merits.

By the Act 5 and 6 Wm. IV., cap. 50, the inhabitants of all rural parishes are obliged to elect from among themselves every year, a person to fill the office of surveyor of highways. The qualification for the office is the possession of freehold property to the amount of £10, a personal estate of £100, or the occupation of premises worth £20 per year. Every person not excused by law from serving the office of overseer of the poor, is liable to be elected parish surveyor. Being elected, if he refuse to act, he incurs a penalty of £20. The person elected will generally be more or less incompetent for the office, because the making and repairing of roads is no more to be understood without previous study and experience than any other business; but it is devolved indiscriminately on the village blacksmith, the carpenter, some one of the half-dozen farmers in the parish, or mine host of the Black Lion, all and sundry of whom are by the law deemed equally capable. The newly-elected surveyor has his own ideas of road reform, and at once proceeds to carry them into effect. Here, however, he incurs a serious responsibility. The same act of parliament which obliges him to accept an office for which he is utterly unqualified, says that if he neglect his duties, or fail to fulfil them properly, he shall be liable to a fine of £5. If, in his anxiety to avoid the consequences of neglect, he should overstep the just medium, and, instead of doing too little, do a little too much, then any ratepayer who may happen to think his rate a penny in the pound too high, or who may have a personal enmity to the surveyor, may object to his accounts when they are brought, as they must be, to be verified by the magistrates. These, in the exercise of their discretion, may think too much has been done, or that what has been done has been paid for too dearly, and they can at once disallow such items as they consider objectionable; the effect of which disallowance is, that the man who unwillingly took an office for the good of the public, for which he felt himself incompetent, and then tried to do his best in it, is exactly the sum of those items out of pocket, and from such decision, upon whatever insufficient grounds it may be arrived at, however (in some cases it may be dictated by personal ill-will), there lies no appeal to any court in the universe.

Such being the state of the law in March, 1856, Mr. Thomas Pougher Greenway was elected under its provisions to fill the office of surveyor of highways for the parish of Broughton Astley. He seems to have been an energetic gentleman, and to have commenced a vigorous effort for the improvement of the roads which had been placed under his charge. Work cannot be done for nothing; and it naturally followed that a pretty heavy bill was incurred. Mr. Greenway's year of office terminated last March, and either himself or his friends were anxious he should be re-elected; but, whether from a feeling that he had led the parish into too large an expenditure, or from some other cause, he was opposed, and, as the result of the poll, another gentleman named Johnson was elected, by a majority of 36. On the 9th of April Mr. Greenway attended before the Lutterworth bench, represented on that occasion by the Rev. J. P. Marriott and D. R. Jones, Esq., to verify his accounts. They were objected to, and the further consideration of the subject was adjourned till the 20th. On that day the case was gone into: a number of witnesses were examined to prove that the work done under Mr. Greenway's directions was unnecessary, or badly executed; evidence to the contrary was also called, and the consideration of the case again adjourned till the 1st of May, in order that in the mean time the magistrates might see the work and judge for themselves. Accordingly, on the 28th, they went over to Broughton Astley, and spent two hours in inspecting the work. On the 1st of May the question was again gone into at Lutterworth, when evidence was given at great length in favour of Mr. Greenway. The magistrates again adjourned the case without coming to a decision. On the 14th they gave judgment, announcing that they had come to the determination of disallowing certain items in Mr. Greenway's accounts, to the aggregate amount of £30 15s. 2d.

The accounts were then passed, with the following differences in the items of expenditure:—

Description.	Amount of accounts as originally presented.	Amounts allowed.
Manual labour	£106 5 11	£78 4 11
Materials.....	85 7 0	77 19 7
Tradesmen's bills	75 6 0	39 4 4
Team labour	52 7 11½	48 7 11½
Other payments.....	23 5 6	18 0 6
		£261 17 2½
Amount disallowed.....		80 15 2
	£342 12 4½	£342 12 4½

Mr. Greenway was naturally taken somewhat aback, and

declined to hand over the money. An appeal was made to the Quarter Sessions held in Leicester, in July, upon which the chairman decided that the court had no jurisdiction. The case was subsequently brought before Mr. Justice Wightman, at chambers, but only one result was possible, and as the conclusion of the whole matter, Mr. Greenway has just paid the sum of £112 11s.: what his own legal expenses may be of course we have no means of knowing.

Having thus given a brief resumè of the case, we have no intention to dispute the decision of the magistrates. They had a difficult duty to perform, and no doubt decided to the best of their skill and judgment; but we would ask, Does not a law which permits such a state of things to arise, manifestly need a revision? We regretted the sudden abandonment of the bill brought in last session, by Mr. Under-Secretary Massey, because we conceived its provisions to be in the main admirably fitted to accomplish their object. It will be remembered that this measure proposed the consolidation of parishes, and the appointment of a district board, partly elective and partly *ex officio*, to be responsible for the highways of the district, over which they were to appoint a professional surveyor. The principal exceptions taken to Mr. Massey's bill related to the *ex officio* members, who in some cases would have been all, or nearly all, clergymen, and who would have completely out-voted the elective members. In the new measure promised next session, we trust provision will be made to secure to the latter at least an equality of votes on the district boards; and it is a serious question for consideration whether the clerical element should be introduced at all, except perhaps in the case of clerical magistrates.—*Leicester Journal.*

THE CRYSTAL PALACE WINTER POULTRY SHOW.

The Crystal Palace at Sydenham has been ever famous for its musical attractions. Mr. Mann's excellent band still daily perform the gems of the best composers of all nations. The recollections of the great Handel Festival are still fresh in the memory of those who attended it; and there are yet to be seen, in the central transept, the great amphitheatre and the gigantic organ used on that memorable occasion. But we doubt whether, in the musical annals of the Palace, great and glorious as they are, there is to be found an occasion when so many instruments were heard at the same time, and kept so long and continuous a roar, as can now from dawn till dusk be heard in that huge greenhouse. To make the concert perfect, there are only two things wanted: Mr. Mann is not present, with his *bâton*, to lead the noisy orchestra, and the performers have evidently forgotten to tune their whistles. But every note—natural, flat, and sharp—is there to be heard, from the deep ophicleides and double bass of the Cochins and Bramah Pootras to the shrill piccolos of the bantams—from the trumpets of the ducks and geese to the bassoon modulations of the turkeys and the hautboys of the pigeons—every sound is intoned, keeping a perpetual roar, that dins in one's ears for many hours after leaving the scene of this noisy festival.

To lovers of poultry, and even to the uninitiated public, who merely admire size, form, and plumage, the present exhibition offers a rare treat, for it is as complete as it is varied and large; and as to excellence and perfection, we have heard several exhibitors, boasting of great experience in these matters, declare that it has never been excelled, if ever equalled.

To give an idea of the immense number of fowls now congregated in the long and spacious gallery situated at the south extremity of the Palace, we subjoin an abstract of the various classes, and the number of birds exhibited in each.

Classes 1st, 2nd, and 3rd compose the Spanish, of which there are 90 old birds, 147 young ones hatched in 1857, and 17 single cocks; altogether 254 birds.

This valuable breed is very well represented; but, notwithstanding their excellence, when compared with English game and Dorking breeds, they sink into comparative inferiority, yielding the palm of elegance to the one, and of size, compactness, and weight to the other.

The 4th, 5th, 6th, 7th, and 8th classes comprise the Dorkings, which have never yet justified to so full an extent the well-deserved popularity they enjoy. For well-proportioned bulk, weight, delicacy of plumage, and well-harmonized outlines of shape, this admirable breed is second to none in the world; and their extraordinary muster at the Crystal Palace exhibition clearly shows the advantages resulting from their being bred at our farmsteads and around our cottages. It may be proclaimed as the English breed of poultry *par excellence*. It is substantial and delicate, attaining early maturity, and pronounced by all gourmets as the most savoury bird on the table. What else can be wanted to give them the pre-eminence over all other breeds?

Of these there were no less than 153 old birds, 303 chickens of 1857, and 46 single cocks; in all 502 birds! In these classes, four cocks exhibited by Mr. Fisher Hobbs, so celebrated for his breed of Dorkings, were greatly admired; and one of them obtained the second prize.

We next come to our old friends the Cochin Chinas, of bygone celebrity. They are comprised in the 9th, 10th, 11th, 12th, 14th, and 15th classes, and number of old birds, both buff and white, 75; of chickens hatched in 1857, 159; single cocks, 31: altogether 265.

All we can say of this class is that if such birds as the majority of those which are exhibited at the Crystal Palace had existed at the time of the Cochin mania, great as were the prices then demanded and readily paid, they would have been still greater and better justified. In size, purity of plumage, less awkwardness of shape and gait, and smaller size of bones, they have been greatly improved; but notwithstanding the evident progress they have made, they must nevertheless yield the palm in every respect to their first-cousins and neighbours, the Bramah Pootras, which comprise the 16th, 17th, and 18th classes, numbering 36 old birds, 63 chickens—such chickens!—hatched in 1857—and 13 single cocks; in all 112 birds.

Over the rows of pens, containing the bass instruments of the noisy concert, stand in all the pride of their gait, the brilliancy of their plumage, the flash of their brilliant eye, the eagle shape of their fine head, the elastic and firm stamp of their steel legs, the elegance of their shape—the ever-loved and petted old English game breeds. And right beautiful is that proud and defying array of their pugnacious majesties! They are comprised in Classes 19 to 27, and number of old birds 192, chickens hatched in 1857, 309; single cocks, 34; altogether 535 birds!

What shall we say of the other breeds? Indeed, were we to attempt to do justice to all, the short space at our disposal would not half suffice. We are then very reluctantly obliged to dismiss the smaller fry of Gold and Silver-pencilled, and Spangled Hamburghs, so varied and so beautiful in their gay plumage, with the mere mention of their brilliant names—names suggested by the richness of the embroidery with which

they are so gaily decked. We must reluctantly do the same with the fussy and busy-looking tufted Polish fowls, shaking their shaggy helmets as if intent upon the most important business. Our duty would evidently be to merely give a nod of recognition to the tiny Bantam; but we cannot resist the temptation of tarrying a little longer before their pleasant and really charming array. Here you can see the gold and silver-laced, the white and the black, all gay and crowing, turning and twisting in their little pens, as if they took pleasure in showing to the admiring crowd the elegance of their tiny forms and the delicate lacing of their gay feathers.

The ducks, geese, and turkeys are truly astonishing by their great weight: we have heard of ducks of twelve pounds each; and of a turkey weighing thirty-five pounds. A pair of geese exhibited by Mr. Baker, of Chelsea, were certainly the largest and handsomest birds we have ever seen.

We were pleased to observe a few pens of *Crève-cœur* fowls, the well-known Norman breed from the other side of the channel. This truly valuable variety well deserves the attention of poultry-fanciers in England; for weight, early maturity, and the delicacy of their flesh they deserve to be compared with the Dorkings, whilst for the production of eggs they are infinitely superior.

There is one point in this, and other exhibitions of the kind, which has always struck us as tending to divest them of that degree of practical utility with which we should like to see them attended—that is, the absurdly extravagant prices affixed to the various pens of birds. It is very true that a man fixing the price of one thousand guineas for a cock and two hens, merely means he wont sell them; but we apprehend that more modest figures, such as range between five to fifty guineas, are really meant as the selling value of the birds. On this we can only observe, that if poultry breeding, improving, and fancying can only lead to such an unpractical result as this, these exhibitions become deprived of their public utility, and sink at once into the insignificance of hobby displays—solely devoted to whiling away the time of idle men, and gratifying the monomaniac tendencies of inoffensive but useless members of society, having more leisure on their hands than they have the mental power to fill up. The absurd regulation of poultry societies compelling exhibitors to fix a selling price upon their pens, at which they may be claimed, is no doubt the cause of this extravagance. As long as this regulation exists, it may be safely asserted that serious and practical men will keep aloof from such exhibitions, leaving the pursuits they encourage to sinecurist clergymen, retired tradesmen, shelved officers, old ladies, and to those who speculate upon the weaknesses of the rich and idle.

THE GOVERNMENT ON THE AGRICULTURAL STATISTICS OF SCOTLAND.

It must be admitted that the question of taking agricultural statistics has never travelled quite pleasantly in England. Despite the resolutions of public meetings and the testimony of individual evidence in favour of the experiment, there has ever been an under-current of distrust and opposition. So far, indeed, the Government have had but little to stand on. The practicability of the scheme is still problematical, and Mr. Caird is even now employed in devising some new measure that shall "go down" a little more easily. Nevertheless, there was always one trump-card ready to be played. The statistics of agriculture *might* be collected, simply because they *were* collected. If prejudice, indifference, or ignorance of their effect stayed us here from furnishing such returns, there was fortunately no such inimical influence to encounter but a few hours further on. It was surely a great fact for the Government to handle—a rare weapon to use when wanted—that the statistics of Scotland had been collected by the farmers themselves, under the immediate superintendence of a farming society—That such information was obtained not for a trial of one year only, but that the machinery had gradually been improved upon and extended, so as to become almost perfect in its action, and unquestionably most satisfactory in its results. With such a story to tell us, we might have been kept perpetually in check. The farmers of Scotland have now for some years sent in their returns. So far from feeling any injury from this practice, they appear more and more to take a pleasure in completing the form of such intelligence. They do their work at little or no cost to the State.—And, in short, the whole business is a very happy example of what may be done with a good will and a proper understanding.

But this proper understanding exists no longer. This good will is destroyed. The agricultural statistics of Scotland—or of England, have received something very like their deathblow. Indeed, at this moment we should say such a plan has far more enemies over the Border than it ever had to encounter nearer home. And this suicidal act has been administered by the Government itself. It is traceable simply and directly to a blind adhesion to routine and red-tape. Ben Jonson has told us who works "with line and rule" and by line and rule, and by never looking an inch beyond the line ruled, have we contrived to make foes in place of friends of the great body of Scotch agriculturists.

The murder came out at a General Meeting of the Highland and Agricultural Society, held in Edinburgh a few days since. Let our readers learn from Mr. Hall Maxwell the chief points in this extraordinary affair:—"The statistical inquiry was commenced in 1853 by an experimental trial in three counties. The estimated cost was 900; the outlay was £672. In 1854 it was extended to the whole of Scotland. The estimated cost was £6,000; the outlay was £4,260. In 1855 and 1856 the estimate was £4,000; the outlay, £3,597 12s. 10d., and £3,592 8s. I was permitted by Government to make, in concert with the district enumerators, all arrangements, financial and otherwise, without interference. My accounts were rendered to the Board of Trade; and in 1853 and 1854 I received the thanks of that department for the economy observed and the reductions effected. In August 1855 Mr. Bowring, of the Board of Trade, acknowledged the accounts for 1854 in the following terms:—"I am to acquaint you, for the information of the directors of the Society, that my Lords have been pleased to approve of the accounts in question."

So far certainly so good. The experiment had not only succeeded, as achieving the object aimed at, but had been worked at considerably under the estimated expense; "My Lords" being, naturally enough, "pleased to approve of the accounts." But here, however, our old enemy, Routine, steps in, just, of course, at her dear, old-fashioned, tortoise pace, and demands, under the authority of the Audit Office, in March, 1856, the vouchers for the expenditure of 1854—two years after "my Lords had been pleased to approve of the accounts in question"—and vouchers, too, for everything

—not merely for the most trifling expenses, such as extra pens and cleaning out-offices, but vouchers for *authority* for employing enumerators and clerks. That is to say, Mr. Hall Maxwell, to whom the management of the Scotch Statistics was unreservedly entrusted by the Government, is to give the authority upon which he made an appointment! To detail why he engaged this clerk, or how it was he induced this or that friend to act with him. Then, these friends or acquaintance—the gentry and leading agriculturists of the country, who so ably supported their Secretary in his endeavour to do the thing properly—had, it appears, some slight allowance for necessary expenses, money absolutely out of pocket. But they had more than this. Once or so in a season they assembled their coadjutors of the several districts over a dinner, when they made their arrangements, received advices, and got through similar business it would have been difficult to transact by any other means. Mr. Maxwell paid for these dinners out of the Government grant, and sent in his vouchers that he had done so. But he is to do a great deal more than this. His word is nothing. The Audit-office insists on having the vouchers of the several enumerators that their expenses and dinners have been paid for—something of this kind no doubt:

"Received this day, with many thanks, of her Majesty's Ministers, the sum of six shillings and tenpence-halfpenny, in payment of dinner and toddy, supplied to me by the landlord of the Caledonian Hotel, as one of the Agricultural Enumerators.

(*Signed*) "STUART, of Stuart.

"Witness, Sawney McSanday, the waiter."

But one sickens of such absurdities. Mr. Maxwell with admirable temper completed the returns of last year, and then, of course, withdrew in disgust from any further association with such powers as he found he had to deal with. It is not too much to say that the whole of Scotland goes with him. The enumerators, as a body, have passed resolutions approving of what he has done. He acts directly under the sanction of the Highland Society, and on the close of the explanation he offered, was specially complimented by the Duke of Buccleuch, Lord Rosslyn, Lord Kinnaird, Sir John Forbes, and other speakers. There is no question but that under his superintendence these statistics have been taken in the most perfect manner possible. It is scarcely too much to say, that no other man could have done the business so well. He undertook and performed a Government contract most successfully, and with only one mistake. He did not avail himself to the full of a contractor's rights. He did not spend all the money he might have done. Instead of returning a thousand or two annually, what would have been easier than to have accounted for—as they want accounts—the maximum allowed him? It is a standing joke in many such a business as this, that "no money is returned." A smart sharp fellow would have run it out to the very halfpenny. The Government did not appreciate the man they had to work with; but, unless we are much mistaken, they very soon will.

An attempt has been made to consider Mr. Maxwell merely as a paid clerk or government official. That is, he received for each year's services an acknowledgment of some two or at most three hundred pounds. To do the same work as it has been done, or half as well, will necessitate "an appointment" of at least from fifteen hundred to two thousand a-year. But we question very much whether we shall have any more Agricultural Statistics from Scotland. Indeed, this is not, after all, the great thing with the Government. The statistics they want is the absolute price of a leg-of-mutton dinner, and what is spent in more pens, wafers, and red tape.

If ever there was a fatal mistake, it is the treatment of the Highland Society by "My Lords" of the Treasury. They have put back Agricultural Statistics to a status something far worse than what it was when the Scotch Society took them up, and have contrived for themselves some very up-hill work to do over again.

THE ADVANTAGES OF A DAILY REGISTER OF THE RAIN-FALL THROUGHOUT THE UNITED KINGDOM, AND THE BEST MEANS OF OBTAINING IT.

The Society of Arts appears to be more and more ambitious to rank as an agricultural authority. It is no longer content with one paper or so on the subject, in the course of a season. On the contrary, these now crowd in upon us in very rapid succession. The new year's list, running up to the beginning of April only, has already three evenings to be devoted more or less directly to the improvement of the soil. Unfortunately, however, there is little promise of the most being made of these occasions. Of course the first object should be to ensure the attendance of as many men practically interested in the question, as it is possible to assemble together. Their conveniences should be especially consulted; as their presence must tend materially to put a stamp and value on the proceedings. Within the last year or two a very fair sprinkling of agriculturists have joined the Society, while still more have accepted the occasional invitations offered them. Now it is well known the majority of these come up the first week in every month. There is the discussion at the Farmers' Club on the first Monday in the month, and the council meeting of the Royal Agricultural Society on the first Wednesday morning. The meetings of the Society of Arts are on the Wednesday evenings, and yet not one of these rural topics is put down for such times as the country gentlemen may be amongst us. Mr. Algernon Clarke is to speak to "Steam-cultivation" on Wednesday, February the tenth, instead of the third—just, in fact, a week too late for his audience. Monsieur Trehonnais is to compare "French Agriculture past and present" on March the seventeenth, whereas the opening of the following month should clearly have been selected. Even in these railway days farmers cannot afford to be perpetually running up to London: and we know they now so plan their arrangements as to kill all sorts of birds with one stone. Ask Mr. Hudson how many visitors he has at other times; or inspect the Club-rooms later on, and we shall find that our friends have got into a habit of accustoming themselves to this first week.

Do not let it be supposed that we speak without some showing. On only Wednesday last, Mr. Bailey Denton, a gentleman well known amongst agriculturists, read a paper at the Society's house in the Adelphi, bearing on a subject at present of particular importance to the farmer—that of drainage. In a not overnumerous audience which assembled to greet him, we noticed one practical agriculturist, Mr. Fisher Hobbs.

We will not say that either Mr. Clarke or M. Trehonnais will meet with a similar reception; but we have little doubt but that the character of the company will, or would have been, very different had Mr. Denton taken the first Wednesday in February, Mr. Clarke the first in March, and M. Trehonnais the first in April. There is a wonderful want of method in all this.

Mr. Bailey Denton discoursed again on his pet theme, and he argued on it as every sensible man now does. We are the victims no longer to dogmatic assertion or despotic sway. The Professor, who harps but on one note, or, Paganini-like, plays on a single string, charms us no longer. The rule of three, or of four feet has lost its force. It is no further to be regarded as without an exception. On the other hand, we study the particular nature of the soil, we consider its situation as liable to atmospheric influence, and sum up a variety of similar causes, ere we venture the application of our remedy. Mr. Denton's paper had this direct tendency. He spoke "on the advantages of a Daily Register of the Rain-fall throughout the United Kingdom, and the best means of obtaining it"; and every word he said only went to show how our practice must vary according to the difference of soil, climate, and locality. The unintentional moral, moreover, which he conveyed to his hearers was, that every-one must think and act more or less for himself. Indeed, to be of any peculiar value, each one of us should keep his own rain register, as many even now do. If Mr. Denton's address lead to any useful result, it must be to this. At the same time we are bound to say that his paper of Wednesday is by far the least practical of all his effusions. It clearly put too much dependence on the rain test—as manifestly under-rated what had already been done in this way—and advocated a system for doing something better, that not one of his auditory had the slightest opinion of ever seeing carried out. Mr. Denton would map the kingdom out into ten, or even five-mile stations at a cost to Government of twenty-six thousand, or on the other scale of about half as much, per annum. The chairman of the evening, Mr. Sopwith, "thought such a plan was not required." Mr. Rawlinson said "a national system of rain-gaugings must be very costly, and the results would only be useful to a limited extent. No nation could do the work of individuals, nor ever would do such work." Mr. Thomas Webster, F.R.S., "did not regard it of so much importance to know precisely the quantity of rain that fell at each place; and the observations already made were very numerous, and might, he thought, be considered sufficient." And Mr. Greaves "thought Mr. Denton had over-rated the requirements of the case, inasmuch as at the present time a very large number of records of rainfall were kept."

There is, in short, no doubt but that Mr. Denton's enthusiasm has carried him too far, and long beyond the limit of any probable effect to be arrived at by such a means. Still, in justice to him we may quote a few sentences from his paper, on the actual necessity for such a monitor as that he advocates the use of:—"I am bound to record my own conviction, based on an extensive practice in the drainage of land, that there is no information more essential to successful treatment than that which it is the object of this paper to promote, and that it is the ignorance now prevailing with regard to the influence of the rainfall, added to the common belief that drainage is a mechanical operation which an uneducated bailiff or woodman may carry out, that has led to the discredit attached to the drainage executed under Government auspices, and has fostered the opposition of certain members of the Central Farmers' Club. As a proof of how little attention landowners have hitherto paid to rainfall, I may mention that when I undertook to read a paper, three years back, before the Central Farmers' Club, on the results of under-draining in Great Britain, I addressed more than 300 persons in various parts of Great Britain, who had executed works of under-draining, and asked the following question among several others: 'What is the rainfall in the locality of your works?' I was gratified by receiving 162 answers to my letters, but out of 162 answers there were only six who were able to give me any information as to the rainfall."

As a king, who can do no wrong, does Mr. Denton disparage the opposition of the Central Club. However, let us pass on to more positive proof:—"In the west of England, where the annual fall of rain is 50 inches, some drainage was effected by a parallel system 40 feet apart. It was pronounced a failure. It has been compared with other works of drainage which were satisfactory in result, upon the same geological formation (with soils closely similar in character), drained in the same way, on the east side of Scotland. The rainfall there was 25 inches, and the number of wet days considerably less than in the West of England, and it is more than probable that these differences account for the results. Another instance will render the proposition even more clear. The lias clay, as already stated, runs nearly the whole length of England. It starts from Lyme Regis, where the fall of rain is 37 inches, passes by Grantham, where the fall is 24 inches, and runs out at the north-east corner of Yorkshire, where the fall is 21 inches. Lands of this clay (as similar as soils can be) have been drained in the several localities in a precisely similar manner, with different degrees of effect. The difference in the rain-fall can alone explain the difference of effect. Sixteen inches of rain, which is the difference between the two extremes, is equal to 362,000 gallons falling upon every acre of land, and this excess is nearly equal to the whole annual amount of rain falling on the surface of Essex and Suffolk, in which counties many thousands of acres of clay lands, no stronger than the lias, are now being drained at a cost of from £5 to £6 per acre. This is a striking fact; but it will be rendered still more striking by reference to the Registrar-General's Return for the first three months of the year just closed. There it will be seen that the rainfall, for that period, at the three places named, was respectively 9 inches (Little Bridy), 6 inches (Grantham), and 3 inches (Scarborough). Hence it follows that the drains in Dorset would be required to do three times the work of drains in Yorkshire with the same means of doing it."

But still we must remember this average rainfall is not everything. As M. Trehonnais suggested, "during a storm an immense quantity of water might fall, and that contingency must be kept in view in drainage, in order to allow the superabundance of water to run out of the land. In his own opinion the average of rainfall had not so much to do in the way of drainage as some people seemed to imagine, because drains must be laid in such a manner as to give an outlet for the immense body of water that might come suddenly upon the land." Mr. Rawlinson, again, maintained that "in all cases the engineer must guard, above ground, against maximums, and, as far as is possible, ascertain what these were likely to be, and then work on the safe side. In all cases the rain-gauge should be consulted for minutiæ and for details; but for maximums, such as land-floods, valley outfalls of streams and rivers must be gauged."

In fact, the argument was altogether overstrained. Although there were no farmers to meet what was advanced, fortunately a few scientific men took up the discussion. These served at once to correct the somewhat too sanguine notions of Mr. Denton, and give to the proceedings a more stable character. The meeting does not promise to leave any very lasting impression.

THE PRESENT STATE OF VETERINARY SCIENCE.

Difficult indeed is the choice of a profession. There is scarcely one but the ranks of which are already overcrowded. Youths qualify themselves as medical men, to become clerks or guards on railways; while gentlemen learned in the law are waiting at table in Melbourne, or horse-breaking in the Bush. Divines and soldiers find it alike difficult to get on; and too often end as they began—but as curates and subalterns. Even farming, as a business, requires more and more capital to be fairly engaged upon; and trade of almost every kind is beset with opposition. But a few years since, to be sure, the famous Fitz-Boodle gave to younger sons some further opportunities, which, however, appear to have been scarcely appreciated. We are still languishing for some eligible pursuit, wherewith to employ the rising generation. As a relief—a sort of tributary stream to those already overcrowded with traffic and commerce—is there none we can embark upon? Is there nothing beyond Law, Physic, and Divinity? Or is there no opening to us but what emigration offers, or the fortune of war provides? If a lad is yet anxious to work his way in his own country, is there really no other call for his services, or no pursuit that might be turned to a better account than it now is?

Let us see. Our canny friends over the Border would at least appear to think so. Very recently there has been established, in Edinburgh, a new Veterinary School, at the opening of which a well-known professor, Mr. John Gamgee, delivered the inaugural address. It is altogether above the level of such orations; and is especially remarkable for the bold and unbiassed view Mr. Gamgee takes of his own profession, and the progress it has made. We are generally prone to consider this as very satisfactory. The difference between the intelligent educated veterinarian and the village farrier, with his infallible drinks and messes, was at once apparent. Perhaps "the college man" has not always taken that position he might have done; but still every one felt he was a change for the better, and we saw him prescribe for a sick horse or prize ox with far more confidence than we could have done had a grimy Vulcan or half-drunken cow-leech yet been concocting his curious spells before us. Nevertheless it would seem that the art is by no means equal to what is demanded of it. "Hundreds of thousands of pounds," says Mr. Gamgee, "are annually lost on British soil, which might be saved if the veterinarian could be found wherever he may be in requisition, and if at the same time *suitable training* had rendered him a useful man." Our lecturer strengthens this opinion with a ready application of what recently has occurred and is still occurring amongst us. Speaking as to the investigation of morbid phenomena in animals, he says:—

"The last few years fully prove, even with reference to the epizootic diseases of Great Britain, how imperfect is our knowledge respecting them, and how insufficient have been the inquiries. It is impossible that a person, aware of what should be the qualifications of a veterinarian, can unblushingly read the reports which have spread from various parts of the United Kingdom respecting murrain amongst cattle. Those who read the daily newspapers might often be led to ask, Have we no veterinarians in Great Britain? It is said that a dozen animals have died altogether on one farm, and that in some districts the best part of a hundred valuable oxen has been swept off, in a manner as quick as it has been mysterious, and there is no one at hand to furnish the world with anything like a correct account of the real facts of the case. A plague is spreading from the Russian steppes; it is supposed to have made a leap close to the west coast of Ireland, or in the north of Scotland: we know nothing about the cause of death there; but we must go to Hungary, to learn what might be learnt at home from books written almost centuries ago, though certainly in a foreign tongue."

This is undoubtedly very hard hitting; but if it is true, we must all have been something more than apathetic. Mr. Gamgee himself characterises the evil as chiefly attributable to a want of hands. He, in fact, opens a new profession to us. The veterinary art has not for some years had anything like justice done to it. It is not properly nor sufficiently studied, in the first place; while in the next, there is a sad scarcity of practitioners, even qualified as they now are. In England we had certainly thought a veterinarian was by this pretty generally within hail. In Scotland, however, with nearly 8,000,000 animals, "we could count little more than 120 veterinarians. Am I to understand that Scotland can only support one veterinary surgeon in every 230 square miles of surface? As might have been expected, there is a greater or less congregation of these 120 practitioners in the larger towns; so that many considerable districts, and even entire counties, are unprovided with practitioners of the veterinary art, obviously to the serious detriment of the public interest. But, even where they are congregated, their insufficiency is too manifest; and the farmers in the three Lothians can give startling testimony, if asked what kind of advice is to be obtained when their animals are sick, and how far they have, in the great majority of cases, to send for veterinarians. Ireland is still worse. Nevertheless, look at the value of her stock! Is it astonishing that unqualified practitioners and blacksmiths swarm and prosper as they do throughout the land?"

We must be understood as taking this up altogether as a farmer's question. There is none more important to him, and no other ill from which he is so continual, and as it would appear, so inevitable a sufferer. If this can be remedied—if we can be provided with a more efficient class of men—if the immense losses now sustained from diseases of stock can be alleviated, then Mr. Gamgee deserves the best thanks we can offer him. He certainly takes very high ground. He quotes numerous instances where the aid of the veterinary surgeon is now altogether dispensed with, so little good has come of it. He has himself gained more information from "some country blacksmiths" than from "many qualified members" of his own profession. At the same time he shows the immense advantage it would be, to have a better organized and more reliable staff. We must take one more extract, at least, suggestive of some good to the agriculturist:—

"Our large herbivorous quadrupeds are peculiarly liable to diseases of the digestive organs. These are very easily prevented; but as animals are badly kept, the prevalence of those maladies is so great, that it is quite matter of surprise. As I have elsewhere said, throughout Scotland devastation by colic is devastation as by a plague. In Mid-Lothian, the loss by colic, inflamed stomach, and inflammation of the bowels, was at least 37½ per cent. of the animals that died of disease in 1851, about 28 per cent. in 1852, upwards of 40 per cent. in 1853, nearly the same in 1854 and 1855, and upwards of 45 per cent. in 1856. An influential farmer of East Lothian, at a meeting of the Highland and Agricultural Society, was alluding to the ravages produced by this disease,

and of the utility of calling veterinary surgeons to attend the suffering animals, or of following out the indications met with in the popular treatises on veterinary medicine in the English language. He believed animals died quicker when subjected to treatment; but he wished a prize to be offered for an essay on the disease. Before, and since then, I have heard many farmers express the same opinion; but it is likewise an undoubted fact that, under proper management, instead of about 40 per cent. of the animals that die of disease dying of colic, there should be a per-centage of *one* or *two*."

We confess we shall be rather curious to see what the members of Mr. Gamgee's own profession say to all this. Undoubtedly he puts their present rank and claims at a very low standard. It may yet remain to be proved how far he is warranted in this, or of what improvement the art is really susceptible. Had he stood quite alone here, we might have hesitated as to giving his opinions any further publicity. But many think with him; and one of the most celebrated of living veterinarians of the English school, Mr. James Turner, has said:—"Of late the veterinary profession has been seized with apathy; no weighty facts, to last out all time, have been chronicled. The remedy and grand requirement of the present crisis is fresh infusion of energetic *spirit* for research."

THE WOOL TRADE OF THE PAST YEAR.

The publication of the annual wool circulars necessarily directs attention to the course of trade in that raw material during the past year, and the future prospects for the wool staplers and manufacturers, as regards this important animal product. Large as the extension of sheep farming has become, and extensively as pastoral occupations are now carried on in old and new districts, they are far from commensurate to the wants of Commerce. Side by side with the exploration and occupation of the squatter and sheep farmer, comes the rolling tide of population, as Emigration proceeds to new fields, and the demand for food becomes equally urgent with that for clothing, since the flocks are more extensively bred and sacrificed for the carcase. In Europe and the United States the number of sheep reared scarcely averages one per head to each of the population. It is only in thinly-settled districts, like the Cape colony and the interior African settlements, Australia, and the River Plate districts, that there is a large excess, and a yearly increasing extension in the exports of wool.

Glancing over the statistics of the past year, it is highly satisfactory to note the large increase in our imports of wool, which sets at rest the fears entertained, a year or two ago, of declining supplies. Although the foreign wools in this progressive increase, compared with the preceding years, have pushed a-head, and show greater strides than the colonial imports do; still there is a steady increase shown in the wool supplies from the colonies each year, of five or six million pounds. The total imports for the first eleven months of 1857 are equal to those of the whole twelve months of 1856. Of the imports, two-thirds were colonial wools, and one-third foreign.

In the colonial wools there is a decline in the receipts of upwards of 7,000 bales from Australia. The Cape show little alteration from the previous year's figures. From India and China there have been increased receipts to the extent of 10,000 bales. We firmly believe that there is a large scope for increased supplies of wool from India, Persia, and China; and more attention will doubtless be paid to the preparation of the fleece for market. Some of these long-stapled wools are already in good favour as a substitute for English combing wools.

Passing now to the European wools, we find an increase of about 21,000 bales from Russia.

The production of wool in Russia might be indefinitely extended. The Government has always fostered this branch of husbandry. Hundreds of thousands of acres of the unoccupied public lands have been given to those who would establish sheep folds on an extensive scale.

Too much attention is, however, paid in Russia to the increase of the flocks rather than the improvement of the breed of sheep. The washing and sorting of the wool are also performed with the greatest slovenliness. Lately the rearing of fine-woolled sheep has become an object of increased attention, and out of the total number of about 50,000,000 sheep in Russia, one-fifth are stated to be fine-woolled sheep.

There was an increase of 3,000 or 4,000 bales of wool from Portugal last year, and about 2,000 bales from Spain: these being chiefly forwarded to France. From Germany we received more than 7,000 bales less than in 1856. The production of wool there would seem to be stationary, if not retrograding, and is by no means adequate to the increasing domestic wants.

Remarks are freely made on a wretched practice which prevails in some parts of Germany and Hungary, and is also followed by the German and Dutch settlers in Southern Africa, and the Western States of America—namely, that of shearing twice in the year. This is both injurious to the animal and to the quality of the wool. Our South American supplies continue beyond an average, and in some instances show an excess: thus Peruvian and Alpaca wool is 8,000 bales in excess.

A rather singular item is the receipt of about 1,400 bags of wool the domestic growth of the United States, the first import of any extent for some years past; and this shipment probably arose out of the panic, and the desire to realize in this market. This wool will probably be reshipped with other supplies for the American market. Considerable attention is now paid to wool growing in the United States. American wool even surpasses many of the foreign wools for its felting properties, and for its suitability for making light or heavy broadcloth. Samples have been obtained from American flocks which contained 2,522 serrations to the inch, while the finest Saxony wools from Hungary will only contain about 2,400 serrations.

The unlimited extent of pasture available, with proper care and shelter, would ensure a large production of wool; but labour is dear and scarce, and large flocks can seldom or ever be kept. Still the number of sheep is greatly on the increase, and is computed at 29,000,000; while the production of wool must be fully 80,000,000 lbs.

Wool is much cultivated in the New England States, especially in Vermont. The Ohio wool-clip last year is estimated to have exceeded that of 1856 by at least three million pounds. The counties in the centre of that State are now as famous for their fine wool as they formerly were for their great crops of wheat.

America, however, does not produce enough wool even for home consumption. The alteration in the American tariff, which admitted in July last wools below 10d. per lb. in value, free of duty, further stimulated shipments across the Atlantic; although some of these arrived at an inopportune time, during the prevalence of the financial crisis.

Returning now to the trade circulars, we find that the consumption of wool has greatly increased in every quarter, and that the growth has not kept pace with it. In Germany however the production is almost stationary. From Australia there is a decline in the shipments, as compared with 1856, of 8,000 bales; and the quantity to come forward for the next sales is also very small. The manner in which prices have been supported, and the fact that, during a period of such unexampled pressure, a quantity of the value of one million sterling could be disposed of at the last public sales in November, at such satisfactory prices, prove the great demand. The home clip is computed to have been somewhat deficient in quantity, partly the consequence of increased demand for stock during the last two years, the improved position of the labouring classes enabling them to expend more in animal food. The consumption of domestic wools has at the same time very materially increased in the worsted districts. There has never (we are told) been a period when the population has been so fully employed, at such high wages, as during the past year. Consumption of woollen goods has, consequently, been unprecedentedly large; and, under all circumstances, there are reasonable grounds to hope this will continue to a fair extent. The continued increase in shipments for some years past has been very considerable; and although in the previous years they had reached a very high point, there is no reason to apprehend any falling-off. Notwithstanding the decline during the latter months, chiefly to the United States, the exports for the past year will greatly exceed any former period, and during the present year, we venture to assert, will show no diminution. A staple which, in its raw state, is worth annually here £7,000,000 or £8,000,000, and of which we ship manufactures to the value of £12,250,000, is necessarily one of high importance in an industrial point of view, and one in which many hands and much capital are engaged.

CENTRAL FARMERS' CLUB.

SUBJECTS FOR DISCUSSION, 1858.

FEBRUARY 1.—The Necessity of a Uniform System of Weights or Measure in the sale of Corn and other Agricultural Produce throughout England and Wales. Proposed by Mr. Owen Wallis, Overstone-Grange, Northampton.

MARCH 1.—The Cultivation and Storing of Mangel Wurzel, and the best modes of using it for Feeding and other purposes—Mr. R. Baker, Writtle, Chelmsford.

APRIL 5.—The Advantages of Guano for Root Crops, and the best System of applying it without injury to the Germination of Seed—Mr. W. Sainsbury, Manor House, West Lavington, Wilts.

MAY 3.—The Breeding, Rearing, and Management of Lambs, as a successful means of providing against Pleuro-Pneumonia and Consumption—Mr. J. Marshall, Riseholm, Lincoln.

JUNE 7.—The Benefit of Pulping or Mincing Roots for Cattle, Pigs, and Sheep—Mr. T. Fordham, Snelsmore Hill, Newbury.

NOVEMBER 1.—The Allotment System: its Uses and Abuses—Mr. H. Trethewy, Silsoe, Ampthill.

DECEMBER 6.—Stock Farming, on stiff retentive Soils—Mr. R. Bond, Kentwell, Long Melford, Suffolk.

*** The Discussions will commence at half-past 5 o'clock, P.M.

ROYAL AGRICULTURAL COLLEGE.

The Sessional Examination of this Institution was brought to a close on December 17th, when the following students obtained the college diploma, and became thereby members and graduates of the institution:—

John Aitken, Ayrshire.
John Dawson, Cragg House, Troutbeck, Windermere.
James F. Hawkesley, Bedfords, Havering-atte-Bower, Essex.
William M'Laughlin, Boraston, Tenbury.

We subjoin the names of those students who headed the examination lists in Practical Agriculture, the various sciences, &c.:—

PRACTICAL AGRICULTURE.—1st, Aitken; 2nd, Greenhill; 3rd, Robertson; 4th, Hills and M'Laughlin; 5th, Dawson and Hawksley; 6th, Duckworth, Horton, and Tomlin.

CHEMISTRY (Organic).—1st, Hawksley; 2nd, Aitken; 3rd, Foden; 4th, Greenhill; 5th, M'Laughlin; 6th, Lloyd and Dawson. (Inorganic).—1st, Gardner; 2nd, Lewis; 3rd, Cornwall; 4th, Lamb.

VETERINARY (First Division).—1st, Hawksley; 2nd, Dawson and Tomlin; 3rd, Aitken; 4th, M'Laughlin and Lloyd. (Second Division).—1st, Lewis; 2nd, H. James; 3rd, Lamb; 4th, Gardner; 5th, Nott.

NATURAL HISTORY (Botany).—1st, Aitken and Hawksley; 2nd, Dawson, Foden, Sayce, Lloyd, and M'Laughlin. (Agronomics).—1st, Cornwall and H. James; 2nd, Nott; 3rd, Jearrad and Adkins.

SURVEYING AND ENGINEERING (First Division).—1st, Hills and Aitkin; 2nd, Tomlin and M'Laughlin; 3rd, Dawson; 4th, Gardner; 5th, Hawksley. (Second Division).—1st, Cary; 2nd, Lewis and Nott; 3rd, Power and White.

PRIZES FOR FARM BOOKS AND JOURNALS.—1st, Gardner; 2nd, Horton; 3rd, Lloyd.

LABORATORY PRIZES.—Classes 1 and 2, H. S. Morgan; Classes 3 and 4, Lamb; Classes 5 and 6, Garratt. Highly commended, Rix and Yarker. Commended, Cornwall.

VETERINARY HOSPITAL JOURNALS.—1st, Hawksley; 2nd, Marrack and Greenhill.

ANATOMICAL NOTE BOOKS.—1st, Gardner; 2nd, Crofts and Lewis.

IMPORTANT DECISION IN THE COURT OF QUEEN'S BENCH,

BEFORE LORD CAMPBELL, AND JUSTICES COLERIDGE, WIGHTMAN, AND ERLE.

MOVEABLE STEAM ENGINES FOR FARMING PURPOSES NOT LIABLE TO TOLL.

THE QUEEN V. MALTY.

This was a case stated by the Worcestershire Quarter Sessions for the opinion of the Court, and which raised the question whether a movable steam engine exclusively employed for the purpose of working thrashing machines was an "implement of husbandry," and, as such, exempt from toll in passing through a turnpike on a turnpike-road. It appeared from the case that the engine in question was drawn by horses, and was following a thrashing machine, also drawn by horses, and both were going to a farm at Upton-upon-Severn, to be employed in thrashing corn. The thrashing machine was allowed to pass through the gate free of toll, but toll was levied upon the steam engine, and the toll-keeper was subsequently convicted for improperly taking toll.

Mr. Powell, in support of the conviction, submitted that the steam engine was an implement of husbandry within the meaning of the act; and if not, that it was so necessarily associated with an implement of husbandry that it came within the spirit of the enactment, and consequently within the exemption. The Turnpike Act exempted, from toll, among other things, implements of husbandry. Under that statute considerable doubt existed as to whether thrashing machines were implements of husbandry; and the 38th of the 14 and 15 Vict., section 4, set that doubt at rest, by providing specifically that they should be so deemed. Dr. Johnson said "implement" was "an instrument of manufacture," and he (the learned counsel) contended that by virtue of the last statute the steam engine in this case was an implement of husbandry within that definition.

The court observed that the steam engine gave motive power to the thrashing machine, and did not actually form a part of it. The thrashing machine might be worked by the hand, by horse, or by water.

Mr. Stretton, on the other side, contended that as the steam machine could be used for giving motive power for printing, spinning, and many other purposes, the fact of its simply going along the road to work a thrashing machine did not make it an implement of husbandry.

Lord Campbell said the court could not be influenced by their opinion of the justice or policy of exemptions in favour of one class of her Majesty's subjects at the expense of another.

They were bound to give effect to the enactments of the legislature, and to see what it intended. Looking to the 3rd of George IV., he should have been inclined to think that a thrashing machine was an "implement of husbandry," and if it had not been for the introduction of the preceding words, "ploughs, harrows," &c., which applied immediately to the tilling of the soil, no doubt it would have been so considered. But the 14 and 15 Victoria, c. 38, provided that implements of husbandry should be deemed to include "thrashing machines;" and the question was, whether a steam engine which was to be used for working a thrashing machine, and for no other purpose, was entitled to exemption from toll. Here the thrashing machine and steam engine belonged to the same owner, were going to the same hirer, and were travelling together. If they had been united, and put into one cart, they would clearly have formed an implement of husbandry; and if the cart carrying the whole was exempted, he thought that a horse drawing a part must be exempted also. But he did limit his opinion to the coincidence of circumstances in this case. He thought that if the steam engine had been going by itself for the purpose of working a thrashing machine belonging to a farmer, it would still have been an implement of husbandry, and entitled to exemption. It came clearly within Dr. Johnson's definition. It was immaterial to say that the steam engine might be employed for some other purposes, because if those purposes were unconnected with husbandry it would be liable to toll. Looking to the fair construction of the Act of Parliament, and what the legislature intended, he thought the exemption in this case ought to be allowed.

The other judges concurring, the conviction was affirmed.

CALENDAR OF AGRICULTURE.

This month is generally very favourable for the operation of ploughing, which must be pushed vigorously in leys and stubbles, and in subsoiling. If the weather be unfavourable, and frosts and snows prevail, continue the work of carting, as directed last month. Feed all live stock regularly and amply, and thrash frequently, in order to afford fresh straw.

In mild weather, pull and store turnips, which are now used in the succession of green rounds and swedes. Give oilcake to the cattle along with the turnips, and salt to the sheep.

Ewes will now require good shelter and juicy food, as the lambing season will commence. Much attention must be paid to young animals at this season: feed the dam, and she will suckle her young.

Lay dung on grass lands; when dry, bush harrow and roll, and pick off by hand all stones and rubbish. Spread mole-hills and tufts of dung, and put gates and fences in order. Float meadows.

During the whole month, fell timber and cut underwoods; splash hedges, and plant new ones. Plant all kinds of forest trees, and cut over those planted last year, as the new saplings that spring from the stems are very vigorous in growth, and often replace a stunted vegetation. Cut open ditches in plantations, and fence well against summer grazing. Fill vacancies in each year's planting of trees.

Open the hills on hop-grounds, and apply strong manures, as rotten dung, brines, and oleaginous substances; dress the roots, and plant in beds the shoots that are cut off, to come on for sets. Collect and prepare all kinds of artificial manures.

In fine seasons, the sowing of grains will commence in the early districts. Sow beans and peas, oats and barley, and spring wheat; sow spring vetches for horses and sheep feed. Sow, on warm and well-prepared beds of ground, cabbage seed, for plants to be set in the field in May and June for a crop.

WHEAT PRICES FOR THE LAST FOUR YEARS.—A correspondent writes as follows:—"As the wheat trade has undergone considerable fluctuations during the last four years, it is interesting to note the monthly changes in the official average of prices. The following table exhibits these variations at a glance:

Month.	1854.		1855.		1856.		1857.	
	s.	d.	s.	d.	s.	d.	s.	d.
January	80	1	72	5	76	6	58	7
February	80	10	70	4	72	6	56	0
March	78	9	67	8	68	11	55	6
April	77	2	68	5	68	8	53	8
May	78	10	73	11	68	0	56	7
June	78	8	76	11	69	6	60	1
July	74	0	76	5	76	1	63	5
August	63	7	76	3	72	10	59	7
September	56	7	75	9	67	10	57	1
October	57	11	77	0	65	5	55	6
November	71	10	80	10	64	1	51	3
December	73	1	80	1	60	3	48	7
Average	72	7	74	8	69	3	56	4

STORING OF TURNIPS.—A correspondent of the *Irish Farmers' Gazette* writes as follows: "Having had occasion to raise a quantity of swedes early in November, for the purpose of sowing wheat, I formed a small pit, tapering to the top, and thatched it securely with a quantity of barley straw, enough to exclude all effects of rain, wind, or frost. The remainder, about 50 tons, I formed in one large pit, about six feet wide at base, four feet high, and three feet wide at top: this remained exposed for a few days, when it received a light coat of turnip leaves, which soon became decomposed, leaving the roots in many places quite exposed. Now for the result. In the pit, which was securely thatched, at least one-half of the roots have decayed, and in that which was exposed to wind and rain they are quite sound. In the latter case I acted under the directions of a large farmer in this neighbourhood, who raises all his turnips in November, and never covers them save with a few of their own leaves, putting them invariably in an exposed position. My reason for touching on this subject is, that in all agricultural works we are advised to choose a dry and sheltered locality for turnips, taking care to have them securely thatched."

DEATH OF MR. STEPHEN MILLS.—It is with sincere and heartfelt regret that we this day record the death of Mr. Stephen Mills; and in this regret our readers generally, we believe, will participate. There is no name more familiar to the county of Wilts than that of Stephen Mills; and there is no man who is more universally respected than he was. Mr. Mills was one of the most extensive agriculturists in England: the farms that he occupied comprised nearly 4,000 acres; and during the recent visit of the Royal Agricultural Society at Salisbury, a large party of gentlemen from different parts of the kingdom took the opportunity of inspecting those farms, and acknowledged the high gratification they had received. The party was afterwards munificently entertained by Mr. Mills; and the thanks of the Royal Agricultural Society were given him for his liberality. Although possessed of much wealth, and of great intelligence, he had no aspirations beyond his station. Affable, friendly, and kind to all round him, his pride and pleasure were in his occupation, and he certainly attained eminence as an English farmer. He possessed some of the best qualities that can adorn the man; and in the discharge of the relative duties belonging to husband, father, master, and neighbour, his conduct was most exemplary—his numerous labourers sorrowing for his death as for the death of an only friend. Above all, he led the life of a Christian—he died the death of a Christian—and there is well-grounded hope that he has gone to receive the reward of a Christian. This, then, will be the highest source of consolation to his bereaved and afflicted family.—*Devizes Gazette.*

AGRICULTURAL REPORTS.

GENERAL AGRICULTURAL REPORT FOR JANUARY.

For the time of year this has been a remarkably fine month. Throughout the country rapid progress has been made in all agricultural operations, which are now in a more forward state than at almost any previous corresponding period. Everywhere, the winter wheats are looking remarkably well; indeed, scarcely a complaint on this head has reached us from any quarter. Thus far, matters are satisfactory enough; but when we turn to the question of the value of wheat, we are compelled to draw rather an unfavourable picture. That grain, notwithstanding that our leading provincial markets have been but moderately supplied with home-grown produce, has met a dull inquiry, and which has resulted in a continuous decline in value. The cause of the present decline, however, is easily traced. In the first place we may observe that, owing to the mildness of the weather, the holders of wheat at Hambro' and some other ports have been enabled to forward large supplies, with orders for immediate sale. Apparently, therefore, the holders in the North of Europe have taken alarm at the prospect held out to them as regards the future, and are turning their produce into money, without waiting the result of our spring trade. Whether this is sound policy, time alone will determine; but our impression is that forced sales at the present moment are highly injudicious, more especially as money in the discount market is unusually cheap and very plentiful, and that prices have been run down far beneath their ordinary level. In the next place, holders of foreign wheat, both in London and at the outports, have shown signs of uneasiness, owing to the heaviness in the various markets in France, and the strenuous efforts making by the French millers to induce parties here to speculate in flour. These efforts have as yet been unsuccessful; but it is a debateable question how long prices either here or on the Continent will show a tendency to decline. And here we may remark that much misapprehension exists in some quarters as regards the exports of produce from France. Some persons have imagined that they are wholly free of duty; but such is not the case, and we here give a practical view of the working of the new export scale of duties: When the average price of wheat in the markets of Saumer, Nantes, and Marans, which establishes the duty for the third section of the third class (say for all the ports between Nantes and Rochefort, inclusive), does not exceed 21f. per hectclitre on wheat, the duty remains nominally as at present, say, 30c. per hectolitre on wheat, and 60c. per 100 kilos on flour. Any advance upon 21f. up to 22f. raises the duty 2f. 40c. on wheat, and 4f. 80c. on flour: in a similar manner, every subsequent advance of a franc increases the duty by 2f. 40c. on wheat, and 4f. 80c. on flour. Thus, if the average price at the markets named should be from 22f. 1c. to 23f. per hectolitre, the duty would be 4f. 80c. per hectolitre on wheat, and 9f. 60c. on flour. The working is similar as respects barley, rye, Indian corn, oats, and buckwheat, the only difference being the price at which the nominal duty changes; hence, any steady upward movement in the quotations would almost immediately lead to a stoppage to the export trade, unless, indeed, prices in this country were rapidly to advance in proportion. Up to this time the quantity of grain and flour received from France has been trifling, and whilst the trade here continued heavy, any increase in the receipts cannot be anticipated, more especially as our farmers now hold an unusually large quantity of wheat of last year's growth, and that, too, of very fine quality. The failure of the potato crop has led to an advance in the value of the best potatoes to *nine pounds* per ton. We perceive, then, that a second quality of food is now positively dearer than good and useful flour, which may be purchased at £8 per ton. From the Continent very few potatoes can now reach us, as the stocks are nearly exhausted, and the supplies in the hands of the growers, both in England and Scotland, are reduced to a narrow compass. Although the consumption of bread in our manufacturing districts has somewhat decreased, owing to the late severe commercial panic, we are of opinion that wheat is now selling at prices far beneath its actual value. The barley trade has been in an unsatisfactory state, and the quotations have continued to give way, in consequence of large importations from the Continent, and the comparatively small supplies taken by the distillers.

Our fat stock markets have ruled heavy throughout the month, and prices generally have given way, notwithstanding that the importations of beast and sheep from abroad have continued trifling. The health of the stock in our leading counties continues good, and the supply of winter food is abundant. After a severe fall in prices, and a great depression in the trade, wool has somewhat recovered itself. At present, however, we have no advance to notice in prices; but there is every prospect of the demand improving, as the stocks held by the manufacturers, both here and on the Continent, are unusually limited.

For good and fine hops, the demand has been rather active, and prices have advanced from 3s. to 5s. per cwt. In all other kinds, however, very little has been passing, at about previous currencies. The supplies in the hands of the factors are very large for the time of year.

Both hay and straw have come freely to hand, and we have no improvement to notice in the trade. Meadow hay has sold at from £2 10s. to £4; clover ditto, £3 10s. to £5; and straw, £1 5s. to £1 10s. per load. The quantities of hay now on hand are by no means so extensive as they were at this period in 1857.

The agricultural advices from Scotland are favourable. Outdoor labours generally are sufficiently forward, but the wheat trade has sympathised with the demand in the south. All spring corn has moved off slowly, and prices have given way. The shipments of produce to the south have been tolerably extensive.

Throughout Ireland, wheat and most other articles have moved off heavily, on easier terms. The imports of foreign grain have been liberal, and the exports to England small. The stocks of produce at the various ports are only moderate.

REVIEW OF THE CATTLE TRADE DURING THE PAST MONTH.

Notwithstanding that only moderate supplies of beasts have been on sale in our leading cattle markets, and that the imports of stock from the Continent have been on a very limited scale, the beef trade has been in a most unsatisfactory state throughout the month. The fall in prices, however, has not been extensive; but evidently the butchers have purchased with more than usual caution. As regards sheep, we may state that the inquiry for all breeds has continued restrictive, and that a fall of fully 2d. per 8lbs. has taken place in the quotations. Calves, however, have ruled steady; but the value of pigs has continued to give way.

That the late commercial panic has led to a considerable decrease in the consumption of meat in the manufacturing districts, is evident from the enormous quantities of beef, mutton, and pork which have lately reached Newgate and Leadenhall markets from some of the midland counties, which, in some seasons, send large supplies to Manchester, Birmingham, &c. The falling off in the demand for butchers' meat in those marts of industry has compelled those who slaughter extensively to forward to the metropolis. Large additions to the metropolitan supplies have of necessity influenced the value of live stock in the other markets, and prices in Newgate and Leadenhall have

been considerably more in favour of buyers than elsewhere. Commercial distress, then, has allowed the production of live stock to exceed the consumption; and, although commerce is slowly improving, we see no reason to look forward to what may be termed brisk markets, or high prices for a considerable period. Against any rapid improvement in the value of live stock, we may place the low price of bread throughout the country; and until our operatives become fully employed, the consumption of food must remain stationary. We think that the theory that production of late years has not kept pace with the demand has wholly exploded: indeed, it would seem preposterous to suppose that the high quotations at which both beasts and sheep have been selling during the last two or three years should not, even in the usual course of trade, have stimulated our breeders to increased exertions. In Holland there is, apparently, a marked change in the system of rearing stock for foreign markets—certainly for our own. That country has, apparently, been drained of its superfluous stock, owing to the immense numbers of beasts and sheep purchased for France, to meet the wants of the people during the last three or four years. We believe, therefore, that prices here will be very little influenced by the amount of supply which the Dutch graziers will have to spare for us during the whole of the present year. From Holstein, we shall, no doubt, receive our customary supplies; but, in a general way, they are not of a quality likely to have much effect upon the prices of good stock. During last month, the following supplies were imported into London from abroad:—

Beasts	432 head.
Sheep	1,307 „
Calves	603 „
Total ..	2,312

In January, 1857, the total arrivals amounted to 4,633; in 1856, to 3,292; in 1855, 9,102; in 1854, 7,919; in 1853, 12,847; and in 1852, to 10,567 head. Thus, it will be seen that the arrivals last month were smaller than in the six previous years.

The total supplies of stock exhibited in the Great Metropolitan Market in January were as follows:—

Beasts ..	20,312 head.
Cows ..	572 „
Sheep ..	80,742 „
Calves ..	1,108 „
Pigs ..	1,759 „

COMPARISON OF SUPPLIES.

Jan.	Beasts.	Cows.	Sheep.	Calves.	Pigs.
1857....	19,949	355	81,200	1,071	2,355
1856....	17,532	435	101,600	757	2,930
1855....	19,717	500	120,470	962	2,625
1854....	19,687	510	95,080	887	2,279
1853....	20,717	480	96,800	2,148	2,360

Beef has sold at from 3s. 2d. to 4s. 6d.; mutton, 3s. 4d. to 5s. 4d.; veal, 4s. to 5s. 4d.; pork, 3s. 6d. to 4s. 10d. per 8 lbs. by the carcase.

COMPARISON OF PRICES.

	Jan., 1854.				Jan., 1855.			
	s.	d.		s. d.	s.	d.		s. d.
Beef, from	3	0	to	4 10	3	2	to	5 0
Mutton	3	2	—	5 4	3	4	—	5 0
Veal....	3	4	—	5 6	4	2	—	6 0
Pork....	3	4	—	4 10	3	0	—	4 4
	Jan., 1856.				Jan., 1857.			
	s.	d.		s. d.	s.	d.		s. d.
Beef, from	2	10	to	4 10	3	4	to	5 2
Mutton	2	10	—	5 0	3	8	—	5 6
Veal....	4	2	—	6 0	3	8	—	6 0
Pork	3	8	—	5 0	3	8	—	5 2

The closing prices of last month show a decline of 6d. per 8lbs. in the value of beef, of 4d. in mutton, of 10d. in veal, and 6d. in pork, compared with January, 1857.

Last month the arrivals of beasts up to the Great Metropolitan Market, from Norfolk, Suffolk, Essex, and Cambridgeshire, were about 9,000 Scots and shorthorns; from Lincolnshire, Leicestershire, and Northamptonshire, 4,000 shorthorns; from other parts of England, 1,550 of various breeds; from Scotland, 2,800 Scots; and from Ireland, 1,340 oxen.

In Newgate and Leadenhall markets, which have been abundantly supplied, the trade has ruled heavy, as follows: Beef from 2s. 10d. to 4s. 2d., mutton 3s. to 4s. 8d., veal 3s. 6d. to 4s. 8d., and pork 3s. 2d. to 4s. 8d. per 8lbs. by the carcase.

REVIEW OF THE CORN TRADE

DURING THE PAST MONTH.

The first month of the new year was characterized throughout by the almost total absence of rain. The temperature has greatly varied; four days at nearly the commencement being very frosty, these suddenly giving way to great mildness, which was followed by cold nights, and eventually by a thoroughly wintry aspect. The dryness of the subsoil has preserved the well-grown wheat plant in health, and the timely appearance of frost has kept it from undue luxuriance, so that it is generally agreed a very fair prospect is on the ground. In the near and southern countries of Europe, as well as on the African coast, the same promise is reported. The first turn of the year showed some tone in the markets, with a slight advance, and the frost led many to thresh freely; but the sudden thaw greatly deteriorating the condition of the larger quantity on show, coupled with the general prostration of trade produced by the late severe crisis, has thrown the markets back to their former dulness, and the balance of the month has been against sellers about 2s. per qr. Future prices must be influenced by foreign arrivals; and these of late having been liberal, through the excessive mildness of the weather, which has kept the Baltic and the northern ports open, millers have had such an abundant choice of samples, that they have partly been independent of English supplies. The return of cold weather, may for a time, lessen their amount; but the universally good wheat crop, and the general monetary pressure seem likely to renew the abundance in spring, and certainly abate the prospect of a much better remuneration to English growers. The failure of the potato crop is, however, likely to be then felt; and should any mishap occur to the growing crops, there would be nothing to fall back upon but the surplus growth of one favourable season. The circumstance that the French markets rather decline at present, is little to be depended on, for they are not sufficiently low to leave a margin for profitable shipments here, and France, with her numerous population and large consumption, may require much foreign produce before the new harvest. From America some quantity may come; stocks at New York having somewhat accumulated, and but a small portion of the western growth being used up; but the

markets are yet comparatively firm, and the effects of the crisis seem passing away. The following quotations from foreign markets show the relative difference with our own. The price of fair wheat at Paris was 41s. 6d. to 42s. 6d. per qr.; but on the coast at Nantes, red wheat was 43s. to 44s. per qr. At Marseilles, African hard was worth 50s. per qr.; Polish, 36s. per qr. Good red wheat at Antwerp was quoted 44s. to 45s., white to 46s. per qr. Rotterdam quotations were 35s. 6d. to 44s. 9d. per qr. At Hambro' wheat on the spot was 45s. 9d., of good quality. The rates at Stettin were 38s. to about 42s. per qr. The best wheat at Dantzic was worth 47s. per qr. Spain, with a much better crop than last year, requires imports. Seville, after a heavy fall, still quotes 55s. per qr. for native white or Blanquillo wheat. The port of Odessa has continued open, and with many vessels arrived, 40s. 6d. per qr. has been made of Ghirka wheat free on board, worth in London only about 43s. per qr., after payment of freight, duty, and expenses. Soft wheat at Constantinople was quoted 41s. 6d. per qr. At Berdianski, where the port is closed by frost, with a stock of 40,000 qrs., the top price of red wheat was 42s. 9d. per qr., worth 46s. to 47s. per qr. in London. The inferior white wheat of Egypt was worth about 28s. per qr. at Alexandria, while in this port the value is about 32s. or 33s. per qr.

White Southern wheat at New York was quoted 1 dol. 30 c. per bush., equal to 44s. per qr., red 1 dol. 15 c., equal to 39s. 7d. per qr., on which 8s. per qr. should be placed for freight, duty, and expenses; so that there is scarcely a foreign port with which a profitable business offers. Still the love of adventure, and the pressure on holders when buyers are wanting, may bring good arrivals.

The first Monday in London commenced on the back of good foreign supplies, with but moderate arrivals of home growth. The morning's show from the near counties was small, and there being every appearance of a frost, the best samples in good condition, red especially, obtained 1s. to 2s. more money; inferior sorts were, nevertheless, neglected, though offered at former rates. In foreign the sorts most in demand were new Baltic and Hambro' red, which obtained an advance of 1s., other descriptions being without improvement. The country markets generally responded fully to the London advices; Hull, Birmingham, and Gloucester were 1s. dearer; Boston, Lynn, Newark, and Bristol, were severally 1s. to 2s. per qr. improved; Sleaford, Gainsborough, and Spalding noting fully 2s. advance. The only improved market at Liverpool was that held on Tuesday, when quotations were raised 2d. to 3d. per 70lbs.

The second Monday exceeded the first in foreign supplies, with about an equal quantity of English growth. From Kent the morning's show of samples was good, from Essex only moderate; but the sudden return of a very mild damp atmosphere greatly affecting the condition of the wheat, town millers held aloof, and would only buy at lower prices—say 1s. to 2s. per qr. These offers were generally declined at the Essex stands, but accepted at the Kentish; so that a good part was left over to the chances of next day. The better supply of foreign at such a time influenced some holders, who accepted a similar reduction to clear their cargoes ex ship. On the following day those factors who had declined placing on lower terms agreed to the abatement, and placed their samples without gaining any advantage. Some of the country markets little altered their quotations, as Sheffield, Newmarket, and Portsmouth. More conceded 1s. per qr., as Leeds, Gainsborough, Newark, and Bristol. Hull, Birmingham, and some others, noted the same decline as London, and Wakefield was fully 2s. per qr. down. Liverpool, on Tuesday, gave way 2d. to 3d. per 70lbs, and on Friday there was a further fall of 1d. to 2d. per 70lbs.

The third Monday showed increased arrivals, and though the weather was less damp, and frosty nights had set in, there was no reaction from the previous dulness; for though Kent and Essex made but moderate contributions towards the morning's supply, about another 1s. per qr. abatement ensued, the sales of foreign being very limited at a similar decline. Hull, Boston, Lynn, Leicester, Bristol, and other country markets, were also 1s. per qr. lower; but Louth, St. Ives, and Market Rasen did not quote changed prices. Sheffield, Gloucester, and Portsmouth were down 2s. per qr. Liverpool, on Tuesday, was 3d. per 70lbs. cheaper, but evinced more tone at the week's close.

The fourth Monday had less additional foreign, but rather more English wheat generally, though Kent and Essex combined showed but few samples in the course of the day. The royal marriage taking place this day had its influence on trade, there being but a slight attendance; and as town millers had agreed to lower the price of their best flour, there was very little done. The Kentish hoymen were willing to accept 1s. per qr. less, to clear their stands; but Essex factors scarcely lowered their terms, the quantities on hand being small. The prices of foreign were not changed: but sales were entirely retail and partial. Liverpool on Tuesday did not alter prices, but Leeds was 1s. per qr. lower. The foreign arrivals during the four weeks, into London, were 66,644 qrs.; the English, 13,618 qrs.; giving an average weekly supply of 20,065 qrs., which shows a slight increase over the previous month. The month's total exports were only 500 qrs. wheat, 161 qrs. oats, 20 qrs. beans. The foreign supplies for the United Kingdom in Dec. were 486,299 qrs. wheat, 509,811 cwt. flour. During the four weeks in January, the imports into the principal ports of Great Britain, in wheat and flour, were 344,716 qrs. The principal change in the flour trade has been in the best quality town-made, which, up to the fourth Monday, was 47s. per sack, and then reduced to 43s. per sack. In Norfolks there have been slight fluctuations; but the total decline has been only 1s. per sack, the month commencing at 33s., and closing at 32s. American and French samples have been offering at gradually easier rates, though the importation of neither has been heavy. In country flour, the receipts of the four weeks have been 71,217 sacks: in American barrels, 20,696; and in foreign sacks

(principally French), 9,570 sacks; giving a weekly average of 20,196 sacks 5,174 brls., which shows some deficiency as respects last month's supplies. In Paris, the fine four marks of the best makers is quoted at 48f. 50c., = 31s. 4d. per sack English; but the expense of transit to the coast, with freight, and English and French duties, &c., leaves little inducement to import, as 38s. here could scarcely be depended on.

The barley trade throughout the month has been heavy, with generally declining prices. The first Monday opened cheerfully, with 1s. per qr. advance on malting descriptions, and some improvement on secondary and grinding sorts; but this was the only market with the slightest animation, the second Monday losing the previous advance on fine descriptions; the third still further declining on distilling qualities; and the last being the heaviest of all, with a downward tendency for anything but picked samples for maltsters. This dulness has not arisen from overwhelming supplies, as the receipts have been below those of last month; but the sale of malt being slow and difficult has affected the best samples, while the low prices of maize, oats, and beans have made the cheaper descriptions less in request. It now seems too late to expect any rally in malting sorts; but as we have never found the foreign importation beyond the demand, as feeding sorts get scarce towards the season's close, we think an improvement very likely. The four weeks' supply has been in English sorts, 14,570 qrs.; in foreign, 39,536—giving a weekly average of 13,526 qrs.

The malt trade, as already noted, has been limited, but prices have scarcely varied through the month, 70s. being about the highest quotation for fine pale.

Oats are the only article in corn which show some advance in prices in the month's course, and this has arisen entirely from the unusual smallness of the supplies. The balance of the month's fluctuation shows 1s. per qr. in their favour. The first Monday was 6d. per qr. dearer, having the smallest show of any on board ship; the second also showed a further rise of 6d. to 1s. per qr.; the third was quiet on increased arrivals; and the last, with only an average quantity, yielded 6d. per qr. on foreign, and 1s. per qr. on Scotch samples. There remain on hand many granary samples of an inferior kind; and till these are cleared, moderate arrivals must have their influence; but as the season advances we rather look for higher rates than otherwise, from the extensiveness of the demand, and the deficiency of the English and Irish crops as to quantity. The four weeks' arrivals in London have been as follows: Of English, there were 3,659 qrs.; of Scotch, 7,689 qrs.; of Irish, 3,158 qrs.; of Foreign, 43,535 qrs.—in all supplying an average of only 14,510 qrs. per week, and being 6,400 qrs. weekly less than during last month.

The bean trade has been heavy, from the mildness of the season and largeness of foreign arrivals; the only change noted as to value was a fall of 1s. per qr. on the last day. The supplies have been 2,728 qrs. of English and 12,762 qrs. of foreign, showing 3,872 qrs. per week, or 340 qrs. weekly beyond last month.

The supply of peas has been very short, with prices unaltered; the demand for boilers being very limited, through the comparative absence of frost and the high rates of duns and maples, leading to other substitutes in preference to paying any further advance. Of English samples there were but 1,710 qrs., of foreign only 243 qrs., giving an average of only 488 qrs.

Linseed, with moderate arrivals, having attracted attention from the late decline, has rather rallied, and an advance of 1s. to 2s. in the course of the month must be noted. Cakes, without being dearer, have found a very ready sale.

The trade in cloverseed having approached its season, has improved, and foreign, as well as English red, has commanded higher rates, though buyers are neither numerous nor eager. In France there has been no excitement; but some advance has taken place in Germany. Good new Bordeaux red here, of which some has arrived, is worth about 65s.; extra purple English, of which little has yet appeared, 75s. to 80s.; fine white is also inquired for, and trefoil commands fully former prices. Canaryseed has been dull, as well as mustardseed. Hempseed, rapeseed, coriander, and carraway have continued a slow sale, with little alteration in value.

WOOL MARKETS.

ENGLISH WOOL MARKET.

LONDON, MONDAY, Jan. 25.—Since Monday last there have been increased inquiries for good and fine fleeces, at full prices. All other kinds of wool continue dull in sale. There is, however, every prospect of a steady revival in the trade, as dealers generally hold unusually light stocks for the time of year.

Per pack of 240lbs.

IMPORTANT TO FLOCKMASTERS.

THOMAS BIGG,

AGRICULTURAL AND VETERINARY CHEMIST,

BY APPOINTMENT, TO H.R.H. THE PRINCE CONSORT, K.G., &c.

LEICESTER HOUSE, GREAT DOVER-STREET, BOROUGH, LONDON,

Begs to call the attention of Farmers and Graziers to his valuable SHEEP-and LAMB DIPPING COMPOSITION, which requires no Boiling, and may be used with Warm or Cold Water, for effectually destroying the Tick Lice, and all other insects injurious to the Flock, preventing the alarming attacks of Fly and Shab, and cleansing and purifying the Skin, thereby greatly improving the Wool, both in quantity and quality, and highly contributing to the general health of the animal.

Prepared only by Thomas Bigg, Chemist, &c., at his Manufactory as above, and sold as follows, although any other quantity may be had, if required :—

4 lb. for	20	sheep,	price,	jar included	.....	£0	2 0
6 lb.	30	,,	,,	,,	.....	0	3 0
8 lb.	40	,,	,,	,,	.....	0	4 0
10 lb.	50	,,	,,	,,	.....	0	5 0
20 lb.	100	,,	,,	(cask and measure		0	10 0
30 lb.	150	,,	,,	included)		0	15 0
40 lb.	200	,,	,,	,,	.....	1	0 0
50 lb.	250	,,	,,	,,	.....	1	3 6
60 lb.	300	,,	,,	,,	.....	1	7 6
80 lb.	400	,,	,,	,,	.....	1	17 6
100 lb.	500	,,	,,	,,	.....	2	5 0

Should any Flockmaster prefer boiling the Composition, it will be equally effective.

He would also especially call attention to his SPECIFIC, or LOTION, for the SCAB, or SHAB, which will be found a certain remedy for eradicating that loathsome and ruinous disorder in Sheep, and which may be safely used in all climates, and at all seasons of the year, and to all descriptions of sheep, even ewes in lamb. Price **5s.** per gallon—sufficient on an average for thirty Sheep (according to the virulence of the disease); also in wine quart bottles, 1s. 3d. each.

IMPORTANT TESTIMONIAL.

"Scoulton, near Hingham, Norfolk, April 16th, 1855.

'Dear Sir,—In answer to yours of the 4th inst, which would have been replied to before this had I been at home, I have much pleasure in bearing testimony to the efficacy of your invaluable 'Specific for the cure of Scab in Sheep.' The 600 Sheep were all dressed in August last with 84 gallons of the '*Non-Poisonous* Specific,' that was so highly recommended at the Lincoln Show, and by their own dresser, the best attention being paid to the flock by my shepherd after dressing according to instructions left; but notwithstanding the Scab continued getting worse. In December I informed the 'Agent for the above Specific,' that the flock was not cured, and that it required their immediate attention. The Agent informed me they should be at once seen to, but did not do so until *five* weeks afterwards, and in the mean time the Scab spread over the whole flock, that I never saw such a disgraceful sight in my life; and when the Dresser was sent over to inspect the Flock, he decided on not dressing them again, as one-third of the Sheep had lost half their wool. I then agreed with an experienced dresser in Norfolk to dress the flock, and when he saw the sheep he declined doing them, as they were so very bad, and the time of lambing so near. Being determined to have the Scab cured if possible, I wrote to you for a supply of your Specific, which I received the following day; and although the weather was most severe in February during the dressing, your *Specific* proved itself an invaluable remedy, for in three weeks the Sheep were quite cured; and I am happy to say the young lambs are doing remarkably well at present. In conclusion, I believe it to be the safest and best remedy now in use.

"I remain, dear Sir, your obedient servant,

"For JOHN TINGEY, Esq.,

"To Mr. Thomas Bigg." "R. RENNY.

In addition to the foregoing, he has very materially improved, as well as considerably reduced the price of his Dipping Apparatus; and he would venture to suggest that no Flockmasters ought now to be without one.

CURTIS ON MANHOOD—SHILLING EDITION.

A MEDICAL ESSAY ON NERVOUS AND GENERATIVE DISEASES.

Just published, the 77th Thousand, with numerous plates, in a sealed envelope, price 1s., or sent, post-paid by the Author, for Fourteen stamps,

MANHOOD : The CAUSE and CURE of PREMATURE DECLINE, with Plain Directions for Perfect Restoration to Health and Vigour; being a Medical Review of the various Forms and modern treatment of Nervous Debility, Impotency, Loss of Mental and Physical Capacity, whether resulting from Youthful Abuse, the Follies of Maturity, the Effects of Climate or Infection; with Observations on a new and successful mode of detecting Spermatorrhœa, and other urethral discharges, by Microscopic Examination; to which are added, Curious and Interesting Cases, with the Author's Recipe of a Preventive Lotion.

By J. L. CURTIS, Surgeon, 15, Albemarle-street, Piccadilly, London.

At home for consultation daily, from 10 till 3, and 6 to 8. Sundays, from 10 to 1.

REVIEWS OF THE WORK.

"CURTIS ON MANHOOD.—Shilling Edition.—77th Thousand.—This is a truly valuable work, and should be in the hands of young and old. The professional reputation of the author, combined with his twenty years' experience as medical referee in the treatment of nervous debility, &c., fully accounts for the immense circulation which this popular and ably-written medical treatise has obtained."—*Sunday Times*, 23rd March, 1856.

"CURTIS ON MANHOOD.—The author has conferred a great boon by publishing this little work, in which is described the source of those diseases which produce decline in youth or more frequently premature old age."—*Daily Telegraph*, March 27, 1856.

CURTIS ON MANHOOD.—The book under review is one calculated to warn and instruct the erring without imparting one idea that can vitiate the mind not already tutored by the vices of which its treats."—*Naval and Military Gazette*, 1st Feb., 1851.

"We feel no hesitation in saying that there is no member of Society by whom the book will not be found useful—whether such person hold the relation of a parent, preceptor, or a clergyman.—*Sun*, Evening Paper.

Published by the AUTHOR; sold also *in sealed envelopes*, by GILBERT, 49, Paternoster-row; HANNAY, 63, Oxford-street; Mann, 39, Cornhill, London; ROBINSON, 11, Greenside-street, Edinburgh; HEYWOOD, Oldham-street, Manchester; HOWELL, 6, Church-street, Liverpool; FRANCE, 8, Side, Newcastle-on-Tyne; ASHLEY, Post-Office, Newbury; FERRIS & SCORE, Union-street, Bristol; PIERSON, Shrewsbury; JULT, Braintree; THEW, Lynn; PEAT, Chichester; LURCOCK, Maidstone; COOK, Ipswich; HUSCROFT, Bury St. Edmunds; DOVE, Swindon; JEAREY, Bridewell Alley, Norwich; SMITH, Cambridge; SLATTER, Oxford; and by all Booksellers and Chemists in the United Kingdom.

A VEGETABLE WHITE POWDER.

The importance of possessing A FINE SET OF TEETH is universally acknowledged by all who attach the due value to *Personal Advantages* and the *blessings of health*. A regular, firm, and pearly row of teeth ever insures favourable impressions, while the indispensable agencies which they fulfil in respect to the functions of health, demand our utmost care and attention in their preservation.

Disorders of the Teeth, however slightly regarded, are inevitably attended with evils which affect the whole system. Whatever renders mastication painful or imperfect, not only lessens our relish and enjoyment of food, but also prevents that perfect comminution and mixture of it with the saliva, which is indispensable to perfect digestion; and hence arise an endless train of diseases of the stomach, while at the same time the body is deprived of its wonted nourishment, and the whole system languishes in a state of discomfort and disease.

Perhaps, among all the disagreeable consequences that follow the fast decay of the Teeth, *an impure breath* must be the most mortifying to its possessor, as it is the most generally offensive in society.

The DECAY of the TEETH arises from various causes; but, principally, it may be attributed to *early neglect, ill health, or the use of Tooth Powders containing mineral and other deleterious acids, which give a momentary whiteness to the teeth, while they corrode the enamel!* The extreme prevalence of this last cause is too well known to need comment. To this fact, indeed, is principally to be attributed the long Botanical research which happily terminated by the most felicitous discovery ever given to the world for the PRESERVATION of the TEETH, GUMS, and BREATH, viz.:—

ROWLANDS' ODONTO, OR PEARL DENTIFRICE,

A WHITE POWDER, composed of the choicest and most *Recherché Ingredients of the Oriental Herbal;* the leading requisites of *cleanliness* and efficacy being present in the highest possible degree. It extirpates all *tartarous adhesions* to the Teeth, and insures a PEARL-LIKE WHITENESS to the *enamelled surface.* Its ANTI-SEPTIC and ANTI-SCORBUTIC PROPERTIES exercise a highly beneficial and salutary influence; they arrest the further progress of decay of the Teeth, induce a healthy action of the GUMS, and cause them to assume the brightness and colour indicative of perfect soundness; while by confirming their adhesion to the TEETH, they give unlimited enjoyment and fresh zest to appetite, by perpetuating effective and complete mastication. The BREATH, also, from the salubrious and disinfecting qualities of the ODONTO, attains a sweetness and fragrance truly grateful to its possessor.

It speedily removes those ravages which children sustain in their Teeth, owing to improper use of sweet and acid articles, which imperceptibly destroy them.

The Proprietors of this Dentifrice pledge themselves, that its efficacy in preserving and embellishing the Teeth far surpasses anything of the kind ever offered to the public.

As the most efficient and fragrant aromatic purifier of the BREATH, TEETH, and GUMS ever known, ROWLANDS' ODONTO has for a long series of years occupied a distinguished place at the TOILETS of the SOVEREIGNS and the NOBILITY throughout Europe; while the general demand for it at once announces the favour in which it is universally held.

Price 2s. 9d. per box.

CAUTION.—To protect the Public from Fraud, the Proprietor's Name and Address, thus—**"A. ROWLAND & SONS, 20, Hatton Garden,"** are engraved on the Government Stamp, *which is affixed on each box.*

Sold by them and by Chemists and Perfumers.

PRICE TWO SHILLINGS.

ROGERSON AND TUXFORD,] [PRINTERS, 246, STRAND.

THE

MARK LANE EXPRESS,

AND

AGRICULTURAL JOURNAL,

IS THE

LARGEST AND THE LEADING FARMER'S AND GRAZIER'S NEWSPAPER,
PUBLISHED EVERY MONDAY EVENING, IN TIME FOR POST.

The object of the Proprietors of the MARK LANE EXPRESS has ever been, to render it in every way the most efficient organ of the Agricultural Classes, to direct and diffuse practical and scientific information of all kinds relating to rural affairs, to be a medium for giving circulation to the Proceedings of the Royal Agricultural Society of England, the Highland and Agricultural Society of Scotland, the Royal Agricultural Improvement Society of Ireland, and of every Agricultural Society and Farmers' Club in the kingdom. All political and party discussions are carefully avoided, except such as are purely Agricultural; since its establishment, twenty-six years since, this course has been steadily adhered to, and the result has been, the accession of a numerous and rapidly-increasing list of subscribers, comprising the most influential Agriculturists in the kingdom.

In times when the position of the Tenant Farmers has been one of great difficulty, the MARK LANE EXPRESS has ever been directed to the advocacy and support of THE RIGHTS OF THE TENANT FARMERS. In stating this, it is not intended to lose sight of that noble principle which the great Lord Leicester so successfully followed; viz., that *liberal conduct towards the Tenant will ever be found to be the most beneficial to the Landlord.*

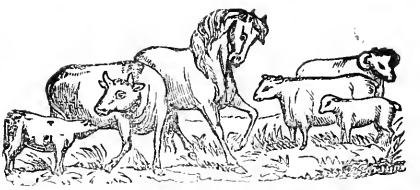
THE MALT TAX.—This is the only Farmer's Paper in London which advocates THE REPEAL OF THE MALT TAX.

In authenticity and extent of Market Information, the MARK LANE EXPRESS stands unrivalled. A REVIEW OF THE CORN TRADE (British and Foreign) fully explains the Causes which occasion the Rise or Fall in Prices, thus affording he Grower and Speculator some grounds for anticipating the stability or future tendency of Prices.

The Latest Reports of the Corn, Cattle, Provision, Wool, Seed, Hop, Malt, and Commercial markets, appear with the leading Country Fairs and Agricultural Meetings. Authentic Weekly Advices are received from all the Important Markets in the kingdom, our Colonial Possessions, as well as all parts of Europe and America.

Office of Publication and for Advertisements, 246, Strand, London. May be had of all Booksellers and Newsmen throughout the Kingdom, price Sevenpence, or £1 10s. 4d. per annum.

Patronized by the Principal Farmers and Graziers in the Kingdom.



CUFF'S FARMER'S FRIEND.

One dose of this invaluable medicine will cure the SCOUR or LOOSENESS in Lambs, Calves, Sheep, Colts, Heifers, Steers, and all Cattle, without leaving costiveness; and given occasionally to Beasts whilst fattening will promote a healthy and thriving condition. It will also perfectly cure the FRET, COLIC or GRIPES in Horses. Price 1s. 8d. or 3s. per Bottle.

CUFF'S FOOT-ROT POWDER

Is a cheap and effectual remedy for the FOOT-ROT or HALT, a single Packet of which will cure One Hundred Sheep, and large Flocks may be soon freed from the Disease by its use. It has been extensively used and highly approved of for nearly thirty years by large Sheep Breeders throughout the Kingdom. Price 1s. per Packet.

CUFF'S FLY, SCAB & MANGE OIL

Will very quickly destroy MAGGOTS in Sheep, and LICE or VERMIN in all animals. It will also cure the MANGE, and SKIN DISEASES in Horses or Cattle, and effectually cleanse a Flock of Sheep from the SCAB or SHAB. Price 1s. 8d. and 3s. per Bottle.

THE BRITISH SHEEP WASH

Is used for Dipping or Dressing Sheep and Lambs, without boiling, to prevent the Fly striking, and the Scab or Shab from spreading, and effectually to destroy TICKS, LICE, and VERMIN in Sheep. Price 2s. 9d., 5s., and 10s. per Jar; or 2s. 6d. per packet.

SHERWOOD'S ORIGINAL DRIFFIELD OILS

Are strongly and confidently recommended for preventing GANGRENE or MORTIFICATION after Lambing or Calving, and for Healing CUTS, STABS, WOUNDS, BRUISES, STRAINS, SWELLINGS, &c., &c.. As these Oils are in constant use by some of the most celebrated Breeders in the world, and have maintained a reputation about fifty years, it would be superfluous to enlarge upon their value and importance. Pints, 2s. 6d., Quarts, 5s.

Prepared by J. H. CUFF, No. 10, Smithfield Market, London, and sold by Druggists and Medicine Vendors

None is Genuine unless signed by J. H. CUFF in writing.

KEATING'S COUGH LOZENGES.

"A SLIGHT COLD,"—if its first symptoms are not arrested, too often lays the foundation of a variety of *Pulmonary Complaints*, including *Winter Cough, Asthma,* and other constitutional derangements. The evil consequences of these disorders may be easily averted or subdued by keeping at hand a supply of the above celebrated LOZENGES, which have now stood the test of public experience for upwards of half a century. The Testimonials to their efficacy have been voluntarily given by the most eminent of the Faculty, as well as by all classes of private individuals. Containing neither opiates nor any injurious anodyne, they may be safely taken by the youngest child or the most delicate female.

VALUABLE TESTIMONIAL.

CURE OF ASTHMA OF SEVERAL YEARS' STANDING.

Cainscross, near Stroud, Gloucestershire.

SIR,—Having been troubled with Asthma for several years, I could find no relief from any medicine whatever, until I was induced about two years ago to try a box of your valuable Lozenges, and found such relief from them that I am determined for the future never to be without a box of them in the house, and will do all in my power to recommend them to my friends.

If you consider the above testimonial of any advantage, you are quite at liberty to make what use of it you please.

I am, Sir, your most obliged servant,

Thomas Keating, Esq. W. J. TRIGG.

Prepared and sold in Boxes, 1s. 1½d., and Tins, 2s. 9d., 4s. 6d., and 10s. 6d. each, by THOMAS KEATING, Chemist, &c., 79, St. Paul's Churchyard, London. Retail by all Druggists and Patent Medicine Vendors in the world.

N.B.—To prevent spurious imitations, please to observe that the words "KEATING'S COUGH LOZENGES" are engraven on the Government Stamp of each Box, without which none are genuine.

KEATING'S PALE NEWFOUNDLAND COD LIVER OIL, perfectly pure, nearly tasteless, and free from adulteration of any kind, having been analyzed, reported on, and recommended by Professors TAYLOR and THOMSON, of Guy's and St. Thomas's Hospitals, who, in the words of the late Dr. PEREIRA, say that "The finest oil is that most devoid of *colour, odour,* and *flavour,*" characters this will be found to possess in a high degree. Half-pints, 1s. 6d.; Pints, 2s. 6d.; Quarts, 4s. 6d.; and Five-pint Bottles, 10s. 6d., Imperial Measure.

79, ST. PAUL'S CHURCHYARD, LONDON.

and Sold by all Druggists.

N.B.—Any gentleman using the Balls may consult the proprietor gratuitously, either personally or by letter.

ESTABLISHED 1812.

TURNIP MANURE. — This valuable fertilizer has been used for the last twelve years with great success by most of the eminent Agriculturists throughout England, and stands unrivalled in the *weight* and *quality* of the bulbs which it produces; it is besides especially beneficial to the *Grain Crops* which follow, while *Clover* is rarely found to fail after the first application. Some of the crops produced by this Manure last year weighed upwards of Thirty Tons per acre. GRASS, BARLEY, CLOVER, and WHEAT MANURES; also BONE, GUANO, and SUPERPHOSPHATE of LIME, warranted of the best quality. Apply to—

H. & T. PROCTOR, Cathay, Bristol.

PROCTOR & RYLAND { Birmingham, Edmonscote, Warwick. And Saltney, near Chester.

N.B.—A Pamphlet on "MANURES, their PROPERTIES and APPLICATION," forwarded on receipt of 12 postage stamps.

IMPORTANT TO FLOCKMASTERS.

THOMAS BIGG,

AGRICULTURAL AND VETERINARY CHEMIST,

BY APPOINTMENT, TO H.R.H. THE PRINCE CONSORT, K.G., &c.

LEICESTER HOUSE, GREAT DOVER-STREET, BOROUGH, LONDON,

Begs to call the attention of Farmers and Graziers to his valuable SHEEP-and LAMB DIPPING COMPOSITION, which requires no Boiling, and may be used with Warm or Cold Water, for effectually destroying the Tick Lice, and all other insects injurious to the Flock, preventing the alarming attacks of Fly and Shab, and cleansing and purifying the Skin, thereby greatly improving the Wool, both in quantity and quality, and highly contributing to the general health of the animal.

Prepared only by Thomas Bigg, Chemist, &c., at his Manufactory as above, and sold as follows, although any other quantity may be had, if required :—

4 lb. for	20	sheep,	price,	jar included	£0	2	0
6 lb.	30	,,	,,	,,	0	3	0
8 lb.	40	,,	,,	,,	0	4	0
10 lb.	50	,,	,,	,,	0	5	0
20 lb.	100	,,	,,	(cask and measure	0	10	0
30 lb.	150	,,	,,	included)	0	15	0
40 lb.	200	,,	,,	,,	1	0	0
50 lb.	250	,,	,,	,,	1	3	6
60 lb.	300	,,	,,	,,	1	7	6
80 lb.	400	,,	,,	,,	1	17	6
100 lb.	500	,,	,,	,,	2	5	0

Should any Flockmaster prefer boiling the Composition, it will be equally effective.

He would also especially call attention to his SPECIFIC, or LOTION, for the SCAB, or SHAB, which will be found a certain remedy for eradicating that loathsome and ruinous disorder in Sheep, and which may be safely used in all climates, and at all seasons of the year, and to all descriptions of sheep, even ewes in lamb. Price 5s. per gallon—sufficient on an average for thirty Sheep (according to the virulence of the disease); also in wine quart bottles, 1s. 3d. each.

IMPORTANT TESTIMONIAL.

"Scoulton, near Hingham, Norfolk, April 16th, 1855.

'Dear Sir,—In answer to yours of the 4th inst, which would have been replied to before this had I been at home, I have much pleasure in bearing testimony to the efficacy of your invaluable 'Specific for the cure of Scab in Sheep.' The 600 Sheep were all dressed in August last with 84 gallons of the '*Non-Poisonous* Specific,' that was so highly recommended at the Lincoln Show, and by their own dresser, the best attention being paid to the flock by my shepherd after dressing according to instructions left; but notwithstanding the Scab continued getting worse. In December I informed the 'Agent for the above Specific,' that the flock was not cured, and that it required their immediate attention. The Agent informed me theys hould be at once seen to, but did not do so until *five* weeks afterwards, and in the mean time the Scab spread over the whole flock, that I never saw such a disgraceful sight in my life; and when the Dresser was sent over to inspect the Flock, he decided on not dressing them again, as one-third of the Sheep had lost half their wool. I then agreed with an experienced dresser in Norfolk to dress the flock, and when he saw the sheep he declined doing them, as they were so very bad, and the time of lambing so near. Being determined to have the Scab cured if possible, I wrote to you for a supply of your Specific, which I received the following day; and although the weather was most severe in February during the dressing, your *Specific* proved itself an invaluable remedy, for in three weeks the Sheep were quite cured; and I am happy to say the young lambs are doing remarkably well at present. In conclusion, I believe it to be the safest and best remedy now in use.

"I remain, dear Sir, your obedient servant,

"For JOHN TINGEY, Esq.,

"To Mr. Thomas Bigg." "R. RENNY.

In addition to the foregoing, he has very materially improved, as well as considerably reduced the price of his Dipping Apparatus; and he would venture to suggest that no Flockmasters ought now to be without one.

	Price in London.		
New and Improved Dipping Apparatus, on Wheels	£14	0	0
Ditto ditto with Iron-bar Drainer	5	0	0
Ditto ditto	4	0	0
Ditto, plain, with Wooden Drainer.....	3	0	0

CURTIS ON MANHOOD—SHILLING EDITION.

A MEDICAL ESSAY ON NERVOUS AND GENERATIVE DISEASES.

Just published, the 77th Thousand, with numerous plates, in a sealed envelope, price 1s., or sent, post-paid by the Author, for Fourteen stamps,

MANHOOD : The CAUSE and CURE of PREMATURE DECLINE, with Plain Directions for Perfect Restoration to Health and Vigour; being a Medical Review of the various Forms and modern treatment of Nervous Debility, Impotency, Loss of Mental and Physical Capacity, whether resulting from Youthful Abuse, the Follies of Maturity, the Effects of Climate or Infection; with Observations on a new and successful mode of detecting Spermatorrhœa, and other urethral discharges, by Microscopic Examination; to which are added, Curious and Interesting Cases, with the Author's Recipe of a Preventive Lotion.

By J. L. CURTIS, Surgeon, 15, Albemarle-street, Piccadilly, London.

At home for consultation daily, from 10 till 3, and 6 to 8. Sundays, from 10 to 1.

REVIEWS OF THE WORK.

"CURTIS ON MANHOOD.—Shilling Edition.—77th Thousand.—This is a truly valuable work, and should be in the hands of young and old. The professional reputation of the author, combined with his twenty years' experience as medical referee in the treatment of nervous debility, &c., fully accounts for the immense circulation which this popular and ably-written medical treatise has obtained."—*Sunday Times*, 23rd March, 1856.

"CURTIS ON MANHOOD.—The author has conferred a great boon by publishing this little work, in which is described the source of those diseases which produce decline in youth or more frequently premature old age."—*Daily Telegraph*, March 27, 1856.

CURTIS ON MANHOOD.—The book under review is one calculated to warn and instruct the erring without imparting one idea that can vitiate the mind not already tutored by the vices of which its treats."—*Naval and Military Gazette*, 1st Feb., 1851.

"We feel no hesitation in saying that there is no member of Society by whom the book will not be found useful—whether such person hold the relation of a parent, preceptor, or a clergyman.—*Sun*, Evening Paper.

Published by the AUTHOR; sold also *in sealed envelopes*, by GILBERT, 49, Paternoster-row; HANNAY, 63, Oxford-street; Mann, 39, Cornhill, London; ROBINSON, 11, Greenside-street, Edinburgh; HEYWOOD, Oldham-street, Manchester; HOWELL, 6, Church-street, Liverpool; FRANCE, 8, Side, Newcastle-on-Tyne; ASHLEY, Post-Office, Newbury; FERRIS & SCORE, Union-street, Bristol; PIERSON, Shrewsbury; JULT, Braintree; THEW, Lynn; PEAT, Chichester; LURCOCK, Maidstone; COOK, Ipswich; HUSCROPT, Bury St. Edmunds; DOVE, Swindon; JEAREY, Bridewell Alley, Norwich; SMITH, Cambridge; SLATTER, Oxford; and by all Booksellers and Chemists in the United Kingdom.

South-Down Rams

The Property of Mr Jonas Webb of Babraham Cambridge for all of which Prizes were awarded at the Salisbury Meeting of the R. A. S. of England July 1857.

Lith. Tint. Printed by Hullmandel & Walton 24 Store St. 1858

THE FARMER'S MAGAZINE.

MARCH, 1858.

PLATE I.

SOUTHDOWN RAMS,

THE PROPERTY OF MR. JONAS WEBB, OF BABRAHAM, CAMBRIDGE.

At the Salisbury Meeting of the Royal Agricultural Society Mr. Jonas Webb distinguished himself more than ever as a breeder of Southdown sheep. In the shearling ram class there were between sixty and seventy exhibited; and the Duke of Richmond, Mr. Rigden, Lord Walsingham, Mr. Overman, Mr. Ellman, Mr. Sainsbury, Mr. Farquharson, and Mr. Harding were amongst the competitors. From these the judges sorted out just half-a-dozen sheep. After much deliberation they gave two of these the prizes, they *specially* commended two more, and they *highly* commended the other two. The three couple were the property of Mr. Webb. In the aged rams he again stood first and second; with another highly commended.

The four rams in our plate are the four prize sheep. The one at the extreme right of the picture is the first prize old sheep, a two-year-old when shown at Salisbury. He was exhibited at Chelmsford the year previous, but not on that occasion noticed by the judges. He is a splendid specimen of the breed; fine and full in form, and noble in appearance. He begins with an exceedingly good head, and the colour of his face, to which he is much indebted, is just what Southdown breeders so much fancy. His neck is full and well set in to the head; shoulders and chine remarkably good and wide, with a tremendous chest and good plaits; his back very wide and full covered; ribs correctly springing, forming a capital rotund frame of great depth. His girth is nearly five feet, his loin and hips wide, but rump rather short, thighs not heavy, and legs a little too upright. His wool is all that can be desired, and plenty of it.—First prize of 25 sovs.

The second prize aged sheep is at the other extreme of the group. This ram is yet more famous. He was the first prize sheep at the Great International Exhibition in Paris, in 1856, and the second prize yearling at Chelmsford in the same year. Considerable discussion, it will be remembered, ensued as to the latter award; many contending he should have been first. He has all the good proportions of his companion, but with a somewhat darker face, a famous fore and hind quarter, a first-rate rump, with twist, thighs, and flank exceedingly good. There has seldom been a more complete specimen of the Southdown—so handsome, so widely proportioned, or so generally good.—Second prize, of 15 sovs.

The centre sheep of the three standing up is the first prize yearling ram. He is a very fine animal, and quite worthy of the distinction he obtained. He is of great size, exceedingly well proportioned throughout, and bids fair to make up into quite a first-class ram. His deep frame, wide chine and shoulders, everywhere well covered—his broad fat back and springing ribs, with capital flank and underpart, all denote this.—First prize, of 25 sovs.

The second, lying down, is scarcely inferior. He has a very correct frame, broad chine and shoulder, well covered, full rump, dark and wide full twist, and unusually good thigh.—Second prize, of 15 sovs.

Mr. Webb has used all these rams himself; while, as some further test of their merit, we may mention that many other of the Southdown breeders honestly admitted that they never sent out such good sheep as they did to Salisbury.

PLATE II.

HOBBIE NOBLE;

A THOROUGH-BRED STALLION, THE PROPERTY OF MR. THOMAS GROVES, OF PLOMPTON HALL, KNARESBOROUGH.

Hobbie Noble, bred by Lord John Scott, in 1849, is by Pantaloon, out of Phryne, by Touchstone, her dam Decoy, by Filho da Puta—Finesse, by Peruvian.

Pantaloon, by Castrel, out of Idalia, by Peruvian, was the sire of many good horses, including Satirist, a winner of the St. Leger, and Ghuznee, a winner of the Oaks.

Phryne, bred by Lord Westminster, in 1840, is also the dam of Elthiron, Windhound, Miserrima,

and The Reiver, all by Pantaloon; of Rambling Katie, and Blanche of Middlebie, by Melbourne; and of Katherine Logie, by the Flying Dutchman. She has been from the first, and still continues, in Lord John Scott's stud.

Hobbie Noble was somewhat renowned as a race-horse. Indeed his two-year-old performances were so good as to make him first favourite for the Derby of his year, for which he ran as Mr. Merry's, having been purchased of Lord John Scott for the unheard-of-price of six thousand guineas. It is not, however, as a race-horse, but as "the best stallion to get hunters" that Hobbie Noble's portrait appears here. This distinction was awarded him at the Salisbury Meeting of the Royal Agricultural Society, when he took the first prize of 30 sovs. against Spencer (the second-prize horse), Theon, The Knight of Gwynne, Little Brownie, Lascelles, Clumsy, Master Robin, The Circassian, Flagellator, Stotforth, and others; the entry in all reaching to fifteen. Still, the award was all one way, and just as any horseman would have decided it—to the best known, best bred, and certainly best looking horse of the lot. Hobbie Noble is in colour a bright bay, with a great deal of power and style about him, a good neck and shoulder, capital deep barrel, strong quarters, but still rather light in the thighs. Taken altogether he is a remarkably fine animal, and a particularly well-topped horse, with a somewhat wicked head, and not, we fancy, to be trifled with. The family, in fact, are not famous for the best of tempers, and his own brother, The Reiver, was one of the most savage horses ever stripped.

Hobbie Noble's career on the turf closed in 1853, and he stood for the next two seasons at Willesden. More recently he has been transferred to the North by his present owner, Mr. Groves, who has always a good horse to show us at the Yorkshire Meetings. Another of his, the Knight ofGwynne, was also in the entry at Salisbury, and selected as the second-best at the unprecedented exhibition of thorough-bred stock at Waterford; while a third, a draught-horse called The Conqueror, an animal of amazing size and substance, took the extra premium at the great horse show at York, in the same month.

Hobbie Noble has been let for the ensuing season, to go to Ireland. None of his stock have yet appeared; but Mr. Groves himself has two or three coming on by him, and there should be something of his under weigh this spring.

WEEDS.

BY CUTHBERT W. JOHNSON, ESQ., F.R.S.

There are few practical inquiries more likely to repay the farmer than those which relate to weeds. Their habits; the vegetation of their seeds; their extirpation; their use, either unburned or their ashes, as manure—are all matters of the highest importance to the cultivator. These were questions which, in what are sometimes called—as if in derision—"the good old days of England," the farmers but little regarded. The custom was then—as, in fact, is yet the case in most newly or only partially-cultivated districts—for the landholder to run away, as it were, from enemies he was too ignorant or too indolent to successfully withstand. When, therefore, he found his neglected and exhausted arable land gradually becoming full of weeds, instead of attempting their extirpation by fallowing, or hoeing, or paring and burning, he took the easier course of abandoning the field for a considerable period to Nature's care. Thence soon came hosts of couch-grass, thistles, and the other denizens of extensively-exhausted arable soils. These speedily crowded together, and formed a mass of herbage which, by its copious growth, ripening, and decay, formed in the soil a collection of organic matters, on which better and more daintily-feeding plants were gradually (after seasons had elapsed) enabled to subsist. And then, after a series of years had brought about this state of things, the farmer was wont to again bring his long-neglected field into cultivation.

It is true that the more enlightened, of those days, denounced this indolent neglect of weeds. Landlords suggested improvements: even the Legislature interfered, evidently, however, with little success. The late Sir John Sinclair has given some amusing instances of such enactments. It seems that, by an old French law, a farmer might sue his neighbour who, at the proper seasons, neglected to destroy the thistles on his land; or he might employ persons to extirpate them, at the grower's expense. In Denmark, there is a law which is directed to the extirpation of the corn-marigold (*Chrysanthemum segetum*); and in Scotland, so far back as the year 1220, a statute of Alexander II. provides for the punishment of those farmers who allowed their land to become foul. Like most of the old statutes of Scotland, the law contains but few unnecessary words. It merely declares that man to be a traitor, "who poisons the King's lands with weeds," and thus introduces into them a host of enemies. It seems that tenants who had the corn-marigold plant in their corn were fined a sheep for each stalk; and that, under the authority of the law to which we have been referring, a Scotch baron—Sir William Grierson—was accustomed to hold *Goul* Courts, at which all those persons were liable to be fined, on whose land more than three heads of that weed were discovered.

It is refreshing to turn from times when such laws were deemed to be desirable, to days when, as at present, the extirpation of weeds is eagerly sought, and a constant and successful war waged against them, without the aid of Parliament.

The labours of modern farmers, aided by the "extirpators," "scarifiers," and other invaluable

implements, have accomplished great things in this war of extermination; but we all feel that still greater advances are yet to be made. Science has of late done good service in the cause. The men who grace the staff of the Agricultural College of Cirencester have well led the way, of late, in the investigation. Professor Buckman has traced their habits, and some of the effects of different modes of cultivation on the growth of the weeds of different soils; and, still more recently, Professor Voelcker (*Journal Roy. Ag. Soc.*, vol. xviii., p. 350) has given, amongst other valuable matters relating to the subject of this paper, the analysis of two of the more common weeds of the cereal soils—the stemless thistle and the couch. His results will be read with deep interest by many of my readers, who, as I described in this magazine for last month, are in many places now collecting their weeds into heaps, and reducing them to an enriching compost by copious additions of common salt or lime.

Professor Voelcker tells us that he selected these two weeds for examination, since they so very generally infest the calcareous clay soils and brashy lands of the Cotswold Hills; but many a farmer, who will read the result of his inquiries far away from the oolite formation, is equally haunted by these unwelcome visitors.

The stemless thistle (*Carduus acaulis*), when examined as just gathered, contained from 25 to 26 per cent. of dry substance, and 74 to 75 per cent. of water. When burnt, the plant yielded 9.66 per cent. of ash. In 100 parts of this ash (and this is the important portion of the inquiry) was found:

Potash and chloride of potassium	27·40
Common salt	·90
Lime	41·44
Magnesia	4·40
Oxide of iron and alumina	2·01
Phosphoric acid	5·36
Sulphuric acid	2·92
Soluble silica and sand	3·50
Carbonic acid, and loss	12.07

The large proportion of lime which this ash contains, the Professor considers, may account for the fact that this thistle delights in the calcareous formation of Gloucestershire. The amount of phosphoric acid which it yields is by no means inconsiderable; and this is evidently united with lime, as phosphate of lime.

Of still more general interest to the farmer is the analysis of the widely-diffused couch-grass, which ever seems to haunt arable soils, and to follow, as it were, the wheels of the plough. The couch examined in the laboratory at Cirencester, on being burnt, furnished an ash coloured slightly red by oxide of iron, derived, no doubt, from the adhering clay. These were found by Mr. Kensington to contain, per cent.:

Potash	10·02
Soda	5·69
Common salt	3·34
Lime	5·58
Magnesia	·04
Oxides of iron and alumina	12·40
Phosphoric acid	9·38
Sulphuric acid	5·33
Soluble silica	24·92
Insoluble silicious matter (chiefly sand)	17·50
Carbonic acid, and loss	5·80

These constituents, the Professor considers, are probably united in the couch-ash as follows:—

	Per Cent.
Carbonate of potash	14·10
Potash in a state of silicate	0·27
Soda in a state of silicate	5·69
Common salt	3·34
Oxides of iron and alumina	12·40
United with phosphoric acid (equal to bone-earth 20·32)	9·38
Sulphate of lime	9·06
Carbonate of lime	3·30
Magnesia in a state of silicate	0·04
Soluble silica	24·92
Insoluble silicious sand	17·50

The ash of the couch, adds Mr. Voelcker, it will be seen, differs in several respects from that of the stemless thistle: the latter contained but little silica, whilst soluble silica is the chief constituent of couch. Again, the proportions of lime and potash in the thistle are much larger than in couch; an interesting fact, on account of both weeds having been collected from soils of a similar character. This is quite consistent with our present information on the particular wants of different families of plants. Thistles are evidently lime and potash plants; and couch appears to require much soluble silica for its growth, a fact which perhaps will explain its occurrence in sandy, as well as in calcareous and clay soils. The two last-mentioned soils often, it is true, do not contain any silica, in the shape of sand, capable of being mechanically separated from the constituents of other soils; but most clay soils are rich in alkaline silicates, from which plants unquestionably can take up soluble silica much more readily than from sand.

The large proportion of phosphoric acid in couch-grass, as the Professor adds, likewise deserves to be specially noticed. United with lime, we have no less than 20 per cent. of bone-earth in couch-ash; a circumstance which throws some light on the experience of many Gloucestershire farmers, who observe, That the fouler the land is, the better will be the crop of turnips, grown without any other manure than the ashes produced by paring and burning the land. "I remember," observes the Professor, "having once walked over a very foul piece of land full of couch, and was not a little amused by the remark of my agricultural friend who accompanied me, 'What fine healthy couch, sir! It will give me next year, I don't doubt, a splendid crop of roots, although I do not mean to put a single load of manure on this land.' Indeed," concludes the Professor, "I have ascertained that a much larger proportion of bone-earth is brought within reach of the turnip plant, in the red ashes obtained on paring and burning, than is contained in a heavy dressing of bone-dust."

These practical observations of the heavy-soil-farmer, as to the fertilizing effects of a good crop of couch-grass, I rather incline to the opinion, are well worthy of far more extended investigation than they have yet received.

The observation, that where there is a good crop of couch, that there a good crop of turnips may be

produced, may, it is true, merely mean the same thing as the well-known almost universal agricultural remark, that where the soil is in a condition to produce luxuriant weeds, that there other and better plants may be made to grow with equal success. It probably may mean merely this: but this well-known fact may be capable of other explanations. Does the couch plant only *collect* together the phosphate of lime already existing in the soil? Would a portion of a field kept fallow and *perfectly free* from weeds for a given period, produce as good a crop of turnips as another portion of the same field in which the couch was allowed to grow, and was then collected, reduced to ashes, and the ashes spread over the soil, thus also well cleansed for the root crop? It is probable that by either mode of preparing the soil about the same results would be obtained; but it might happen that the couch plant would be found to collect the phosphate of lime with more energy or from greater depths than in the case of the ordinary cultivated plants. I opine that we shall hereafter have our knowledge of the source whence plants derive their food considerably modified and extended.

The valuable paper of Professor Voelcker, to which I have been thus alluding, is chiefly directed to the elucidation of the old farming process of paring and burning—a practice which certainly needs a much clearer chemical explanation than it has yet received. It is an operation but ill-adapted to light soils; while on many clays the application of fire is not only attended with benefit to foul and long-neglected soils, but is, in some considerable districts, repeated over and over again, at but moderate intervals of time, with almost continued advantage.

In this research, the labours of the eminent chemist, whose researches I have been tracing, are important, and will probably tend to the extension, on suitable soils, of paring and burning. Some of the conclusions to which he arrives, it is true, may hardly be admitted as decisive; but, after these drawbacks, I would commend his report to the farmer's careful study. He concludes that by paring and burning, 1st, The inert vegetable matter of the soil is made to yield valuable mineral food for plants; 2nd, That the mechanical condition of the soil is improved; 3rd, That the process is not advantageous for light soils.

The cautious way, however, in which the Professor addresses himself to the subject, is well worthy of the farmer's careful imitation. The soils for which that antiquated process is most desirable, are certainly not very numerous; and it is perhaps more than probable that the further our knowledge of weeds and soils is increased, the less occasion shall we find for the employment of paring and burning.

THE STEAM PLOUGH.

Mr. J. Algernon Clarke read a paper under this title, at the customary weekly meeting of the Society of Arts on Wednesday, February 10th, W. Fairbairn, Esq., in the chair. Mr. Clarke's Essay was written and forwarded early in 1857, in answer to an invitation from the Council for an article on such a subject The medal of the Society was subsequently awarded its author; but he was not called upon to read it until something like a year after it was composed. There were very few practical agriculturists present, but nearly all those gentlemen now directly interested in the further development of steam-power to such a purpose. These included Messrs. J. Allen Ransome, John Fowler, Smith, of Woolston, J. Howard, of Bedford, Boydell, Romaine, and Halkett. There were also present Messrs. J. J. Mechi, W. Fisher Hobbs, W. Bullock Webster, J. C. Morton, H. Corbet, Bethell, and T. Scott. Mr. Clarke proceeded as follows:—

Steam-power having been successfully applied to what may be called the mill-work of the farm, such as thrashing, cutting, slicing, grinding, pulping, and preparing the various products and "feeding stuffs," entering into the economy of the farmyard, I take the present subject to be confined to operations in the field; including drainage, preparatory tillage of all kinds, sowing, weeding, reaping, cartage of produce to suitable storing places, and the distribution of manure. And, lest a paper on these topics should extend to an unmanageable length, it will be advisable to be still more restricted, so that, waiving for the present a consideration of draining, manuring, sowing, and the light after-processes of tillage, I come to the first operation of breaking up the soil, and the mechanical preparation of a seed-bed, as the main objects to be accomplished in steam cultivation.

Mr. Hoskyns, whose original views of this subject have moulded the designs of many inventors, and first fully awakened the agricultural world to the importance of steam-culture, teaches us to look beyond our familiar digging, ploughing, harrowing, scuffling, and rolling, as the sole possible modes in which the new motive-power may operate. We should analyze these processes; see what is the end attained by them, and then endeavour to accomplish the desired result with a machine as specially adapted to steam-power, as the present horse and hand implements are to animal-power. Investigating the nature of preparatory tillage, he finds it to consist in "comminution, aëration, and inversion," which it is possible to effect at once, in a single act, and with a simply-formed tilling instrument; and from the fact of horse-traction being horizontal, manual delving vertical, and the "favourite motion" of machine-work circular, he concludes (with an amount of argument and illustration which establishes and fortifies his deductions) that some kind of "revolving cultivator" will ultimately be found best for being driven by a steam-engine. Accordingly, I am prepared to offer what, I believe, to be a new principle of rotary digging by steam-power, calculated to fulfil the various conditions recommended by theory or demanded by practice; but as an essay solely on mechanical tillage, so far advanced and a-head of the times, would be of little more immediate practical value than a history of past attempts and failure, I will first consider the application of steam-power to our existing order of implements.

In the outset let me remark that, although the "favourite motion" of steam machinery is cicular, this is no valid reason why we should reject without trial every

other kind of motion if suited to our purpose, seeing that the steam-engine employs rectilinear motion, continuous and reciprocating, and, indeed, all conceivable varieties of movement adapted to specific ends; and of all practical trials yet made, with the exception, perhaps, of Mr. Romaine's cultivator, far more favourable results have followed from applying steam-power to the haulage of traction implements, than from setting it to drive revolving cultivators. The wonderful rapidity with which steam-thrashing has been accomplished, is owing to the circumstances that there was really nothing new to do; the engine had to turn a sheave (to thrash a sheaf) by means of a driving belt, just as it was accustomed to do in thousands of factories, only it had to be made portable. But working over so great an area as the surface of a field is a novel operation for the steam-engine, beyond the mere application of cog-wheels, shafting, belts, and brasses; and there is difficulty enough in finding how to apply the motive-power at all points of the surface in succession without staying to devise, in addition, more perfect tillage implements than we now possess.

To draw an implement such as the plough, which has been tested, improved, and adapted throughout many centuries, is a simpler and readier problem, than to contrive a new description of tool for performing a hitherto unknown operation, involving, perhaps, a novel system of cultivation altogether; and as in thrashing, the implement will doubtless be speedily improved when once the new power has been applied to it. Again, there is no doubt that intelligent farmers everywhere are prepared to work traction implements by steam, whenever they are convinced that the present ploughing, scarifying, &c., can be done at less cost, all things considered, than by horses. A steam-plough is capable of instant and universal adoption, while a new tilling machine would not only meet with mechanical difficulties, but be a long time in achieving practical and pecuniary success against customs and prejudices cherished for generations. It will be wise to imitate those processes which are now found to produce the best effects, even though this may not be making the most advantage of the power that is possible.

In practice it is found indispensable that the staple of the land should be occasionally inverted—to bury surface weeds, stubble, sward, or manure, and bring up root weeds for extraction; also to fertilize the soil by the chemical and mechanical effects which follow both the exposure of earth that has lain long buried, and the burial of that which has been long treated by rains, dews, winds, frosts, and sunshine. This inverting, indeed, may be said to constitute the heaviest labour of tillage; if we can perform this, we can readily master any after-stirring of pulverization. Breaking-up, without inversion, is getting into favour; but experience at Lois-Weedon and elsewhere shows that a tenacious subsoil should be exposed and weathered before being mingled with the staple. Mere granulation by scratching or rasping, mingling rather than turning over the mass so comminuted, has been proposed as the ideal operation we should aim to accomplish; but, however useful it may prove in some cases, I cannot regard it as calculated to meet all the necessities of our present practice, in which we find that, after certain crops and for various purposes, the soil must be cut or broken into pieces sufficiently large and tenacious to be turned bodily upside down. The pick or mattock may be a valuable tool in some countries—working with a minutely pulverizing effect, and, at the same time, securing a more or less complete inversion—and the plough itself is in some climates a mere grubbing or ribbing tool; but with our moist soils and weeping atmosphere, our principal implements for performing the fundamental process of cultivation have been of necessity the plough that turns a furrow-slice, and the spade that cuts and completely turns over a spit, the plough modified into many shapes, and the spade or fork made equally versatile in its adaptation to deep, shallow, light, strong, or stony land. Of these two implements the plough can be more easily actuated by steam-power than the spade: all hand tools being worked by several different motions intermittent and irregular, and so requiring complicated mechanism to imitate their action, while traction implements, moving with a continuous rectilinear motion, have simply to be drawn along, and with but little modification needful in their present form; hence, the solution of the steam-culture problem lying nearest to us consists in

Steam Ploughing.

On light land, and where shallow work alone is required, the breaking up and inversion of the soil is done with great efficiency by the plough; and when we see the neatness with which leas are "tucked down" by our first-class skim-coultered ploughs, precisely that toughness being left in the slice which is so desirable on such land, we cannot think that any better implement need be there desired. On heavy land, where tillage makes a larger item in the expenses of management, and a cheaper motive power than that of horses will prove the greatest boon, the plough seems to be used merely because the horses cannot dig. The sledging sole does harm: the slices, not sufficiently subdivided, harden, and make work for future dragging and reducing; and inversion is imperfectly effected, because a "harrow-edge" is necessary for securing a good "mould." Deep culture is also needed on most strong lands; yet the farther we dig below the surface, the more is our horizontal traction at a disadvantage. A vertically-descending tool appears to be required, rather than a horizontally-drawn one; and, perhaps, rotary diggers will utimately be found as peculiarly adapted for penetrating and stirring up the subsoil from great depths, as traction implements are for tilling the upper stratum. Such lands will be grateful for a digging or trenching machine driven (not dragged) by a steam engine, whenever it is practically brought to the field. Meanwhile, the most effective implement for deep work on a large scale, in which manual digging is precluded, is the plough, with the subsoiler or trench-plough following. However, in spite of Lois Weedon husbandry, and the larger experience of the Yester farms, deep tillage is not so much sought after at present as a more rapid and economical method of performing ordinary ploughing. Instead of the slow trenching machine (although necessary to the renovation of clay-land farming), everybody is asking for steam machinery that can plough or equally well cultivate, at comparatively small cost, a great area of ground in a little time.

Steam ploughing is not only possible, but is being actually done on a considerable scale; and, without reciting the long history of inventions for the purpose, I wish to consider the various plans now before the public—the results, as far as yet ascertained—and then to make suggestions for further progress.

The first point is, How to apply the power to the implement; and the next is, The construction of the plough or ploughing machine.

As the material to be cut and turned over cannot be "fed" to our machine, we must take the machine over every part of the surface to be acted upon. Is the motive power, then, to be transported bodily over the whole area, as horses are? or is it to be transmitted from a distance? The idea of a locomotive power was the earliest, and certainly the most natural, from observing horse-labour, besides being a corollary from the invention of steam-carriages. And, though it may at first

sight seem ridiculous to harness an engine to an implement, as though its strength, like that of a horse, lay in its legs, yet we have the example of the railway locomotive, which exerts all its power by means of its (rotary) legs, yokes itself in front of a carriage, and pulls with traces, as a horse does. Working on a level and smooth roadway, the locomotive can drag a train of carriages more economically than a stationary engine can haul it with rope; and, allowing for the difference between a galloping railway speed and the sluggish pace required on an arable field, analogy would lead us to expect a like superiority of the locomotive, whether in pulling ploughs or vehicles. I need not enumerate all the attempts at locomotive engines for traversing arable land, but shall notice two only — one "theoretical," the other practical.

The great weight of a steam-engine, with its water and coal, forms the chief obstacle to its transit over a soft or rugged surface; why not, therefore, employ a pneumatic locomotive? In 1839, Mr. Henry Pinkus patented a most ingenious method of applying an atmospheric vacuum, or else compressed air, as an auxiliary for conveying motive-power from a stationary engine to travelling implements. Now, without adopting his proposal of laying down air main-pipes about an estate, and distributing power (as Mr. Mechi does manure) from steam-pumps at the central homestead, might we not take his plan for connecting a light travelling pneumatic engine with air-pumps attached to a stationary portable steam-engine? A flexible tube, coiled on a cage-drum upon the pneumatic locomotive, is paid out as the locomotive recedes from the steam-engine, and wound up as it approaches. By passing and repassing the steam-engine, a length of 200 yards may be ploughed with only half that length of pipe; and as this is merely laid down and rolled up again, very little wear from friction is incurred.

All doubt as to the effectiveness of pneumatic power applied in this way may now be considered as dispelled by the success of a compressed air-engine at Govan colliery, near Glasgow, which has been working for more than six years, without requiring any repairs or adjustment. The air-engine is situated half-a-mile from the steam-engine and compressing-pump; yet, as the pipe conveying the air is of large diameter, viz., 10 inches, the pressure of the air is diminished only 1lb. per square inch in passing through it. However, there is so much nicety and complication necessary in the compressing machinery, and in the apparatus for neutralizing the great development of heat occasioned by the process of obtaining air at only 20lbs. pressure to the inch, that I think the principle must be abandoned, and we must give up, at any rate for a long time, the advantage of possessing such an extremely light as well as powerful locomotive power in our fields.

For making the steam-engine itself an agricultural locomotive, we have Mr. Boydell's "endless railway engine." I need not describe in detail this admirable working-out of an old idea By bridging over hollows and forming inclined planes over obstacles; by stepping, as it were, instead of rolling, and laying down smooth even iron rails on which the wheels run; and still further, by bearing with flat platforms instead of curved wheel-tires upon soft ground, the shoes or rail-pieces marvellously ease the progress of a ponderous machine. And thus the "traction-engine" can climb considerable gradients, as proved at the Salisbury Agricultural Meeting; and whether we adopt the particular form of engine there exhibited, or Mr. Burrell's appliance of the rails to common portable engines, or Messrs. Tuxford's compact and manageable engine on three wheels, in which both the main travelling-wheels are driven, whether turning a curve or proceeding in a straight line, or Mr. Collinson Hall's enormously high-pressure locomotive, with its peculiarly-shaped boiler and steam-chamber maintaining the water-levels always above the tubes, it is now clear that the farmer's engine may be independent of his horses, that it can draw from farm to farm the heavy thrashing-machine it works, and pull home the harvest-sheaves or lead out those loads of farm-manure which now tax the power of our teams so many weeks in the year. From the many experiments made and published, it is certain that the "steam-horse" can drag implements on moderately level land at a very expeditious and cheap rate, which is not surprising when we consider that the engine brings the implements, and the coal and water enough for the day's use, into the field with it; that no tackle has to be laid out and fixed, or taken up and shifted; that the amount of manual labour required is very small, and the time lost in turning and removing comparatively trifling.

How long a traction engine will last in constant field use I am unable to say; but everybody knows how the rough journeys of common portable engines tend to damage and deteriorate them; and though the rails prevent much of the shock and strain which would be otherwise felt, continual travelling over a hard and rugged surface like arable land must have an injurious effect upon a ponderous boiler and machinery. The wear of the rails is also a very serious item. The objection that the great weight is calculated to injure a strong soil by undue consolidation, applies to the traction engine as well as to horses, but not with greater force. For an engine of 8 or 10 tons traversing a field weighs but little more than the number of horses requisite to pull the same implements; and their feet penetrate and injure the ground more deeply than the broad platform rails.

It appears that a momentary emergence of the tubes above the water level in the boiler is not dangerous; but for maintaining a nearly horizontal position upon long inclines, might not ordinary boilers be supported about the middle of their length, and raised or lowered at one end by means of an adjusting screw?

I am very hopeful of the extensive adoption of the traction engine upon very level land, for ploughing or scarifying whole ground; but fear it would be impracticable for working land already ploughed, so much of the motive-power being wasted in carrying itself over rough and yielding furrows or large clods.

It is to be regretted that the adaptation of the ploughs to the traction engine has hitherto been so unfortunate as to prevent the accomplishment of a high quality of work. Mr. Smith, of Woolston, has just patented an improvement in the yoking of the implements.

Before quitting the subject of locomotive engines for traction, I ought to mention Mr. Halkett's recently-proposed system of "guideways," or rails laid 50 feet apart over the entire surface of the land, for the conveyance of the engine and tilling machinery. The advantages promised on clay soils are prodigious, but I believe not the less reasonable and likely to be realized; and I would dwell longer upon the mechanical merits and economy of the plan, did I not believe that the first outlay, of £25 to £30 an acre, effectually debars its employment to the tenant farmer, while there are but few estates, I suppose, on which landowners are likely to apply it, or on which a public company might obtain power to operate. And I prefer to notice schemes of steam culture for tilling our fields as at present laid out, as more immediately practicable and available than those requiring the complete remodelling of estates.

For ploughing, and scarifying, &c., in a hilly country, we must have recourse to the windlass and rope as the best means of transmitting power from the engine to the implement; and it is a question whether this or the traction engine principle is best even for level districts,

Of several plans which have come before the public for working implements by a stationary engine and windlass, only one now survives. Mr. Fowler, having tried one method which wasted too much time in shifting the anchorages, and another which, though with these self-shifting, required a great length of rope, has adopted the system of moving both engine and windlass along the headland. Mr. Smith, of Woolston, adheres to the stationary engine and windlass; for though it involves the use and wear of wire-rope laid all round the field instead of once up and down it, and loss of power also in passing the rope round four anchored pulleys instead of only one, it enables him to employ a very compact form of winding-machine or capstan, and relieves him of the difficulty of moving the heavy machinery along the headland. The anchors at both ends of the work are removed at intervals into holes dug for them by hand labour, and a man is necessary to guide the rope into proper coils on the drums; so that with the engine-man, and a man and boy with the implement, five men and a boy are engaged in working the machinery, beside the horse and hands fetching water. The working cost of deeply breaking-up the soil, at 5 acres a day, including the shifting of the tackle, is 5s. 2d.; and of trenching and subsoiling (3 acres a day) 8s. 8d. per acre; the wear and tear being taken at 1s. 6d. per acre more. The price of the tackle and implement adapted to a common portable seven-horse engine is £220; and the experience of several farmers seems to show that it is worth while to lay out this sum, and then expend the above amount per acre for autumn cleaning and other preparations, even though ploughing itself may be left for horse-labour.

Mr. Smith's method of turning the implement at the end of its course, by simply having it yoked to the ropes by a "turn-bow" or hook in front, is the simplest and readiest possible. I shall refer to his system of tillage by-and-bye; ordinary "ploughing" not being included in it.

But may not this hauling by wire-rope with a stationary engine be pushed too far? When a very great length of running rope is out, the friction of the slack portions of the rope on the ground (the tight parts resting on friction-rollers), that of the pulleys or snatch-blocks on their bearings, the bending of the rope round the pulleys, and other conditions, consume a very considerable amount of power, besides occasioning a large amount of wear; and our object should, therefore, be to place the engine as near its work as may be consistent with no undue loss of time in shifting anchorages and turning the implement at the ends. This was the principle acted upon in the earliest practical trials of steam-ploughing, a medium between the travelling and fixed motive-power being chosen, by arranging the engine with its winding mechanism upon the head-land, and shifting it so as to be always opposite the ploughing. If we have two engines with coiling-drums, one at each end of the field, and two implements moving in opposite directions, the ploughs will be at the least possible average distance from the motive-power. However, the very great prime cost, the cumbersomeness and difficulty of moving so much heavy machinery from field to field, the time lost in adjusting the two implements at the end of their work, and other considerations, are unfavourable to the scheme, except when ploughing is undertaken on a scale of great magnitude, and the engines are constructed so as to be perfectly capable of steaming their own way from farm to farm. A better plan (indeed, the first ever brought into actual operation) is to employ one engine and winding-gear on one head-land, and an anchorage and pulley on the other, both being shifted along as the work proceeds, and a single frame of ploughs being hauled up to the engine or pulley alternately. This is the plan adopted by Mr. Fowler; and, for comparing the saving of power effected, suppose a plot to be ploughed is 200 yards square, with a stationary engine and windlass the average length of rope running at once would be 600 yards, and the average distance of the implement from the windlass 300 yards; with a shifting engine and windlass, the average length of rope out is 400 yards, and the average distance of the implement 200—that is, one-third less. There is a further economy of power in having a direct pull upon the plough with one rope, and round only one pulley with the other, instead of round two pulleys with both ropes, as in the stationary windlass method. There is, therefore, no doubt that Mr. Fowler could haul Mr. Smith's implements with greater results than have yet been attained by the latter gentleman's rectangular method of working the rope; so that it is the simplicity and lightness of machinery and apparatus, rather than economy in working expense, which form the favourable points of the Woolston system. One advantage of Mr. Fowler's plan is also that an unlimited extent of land may be ploughed with the same length of rope, fewer removals of the engine and tackle by men and horses being therefore required. I need not describe his ingenious anchorage, which propels itself onward, with its cutting disc-wheels always in the soil, forming a perpetual holdfast or purchase, or the well-known engine with coiling-drums underneath, which also slowly creeps forward along the headland. A portable engine, by its inherent weight, forms such a capital fulcrum or resistance against the strain of the hauling-rope, that it was well to use it as such; but until we have the combined engine and windlass able to transport itself up-hill and along ordinary farm roads, I must view it as too ponderous and unwieldy for common farm use. One material point should be considered, namely, that to be immediately useful and successful, and patronized by the farmers generally, a steam-plough ought to be adapted to our present portable thrashing engines, now distributed by perhaps ten thousands throughout the kingdom. Mr. Williams, of Baydon, connects a windlass on wheels with a portable engine by means of a strong framing; and though he has not been able, I believe, to work his ploughs without horses assisting, this portion of his plan is on precisely the principle I regard as most feasible, and likely to meet with general favour. Mr. Fowler has adopted a similar method of enabling the farmer to avail himself of the engine he already possesses—the windlass-frame, mounted on large wheels, being so constructed as to embrace an ordinary engine like a pair of shafts, one end of the boiler being supported on this frame, and the other remaining upon its own travelling wheels. It does not take much time to unite or separate the engine or windlass; when joined, they propel themselves forward on the head-land as one machine, and when separated, three horses can take either part from place to place.

At the trial at Stirling, Mr. Fowler's machinery, manufactured by Messrs. Ransomes and Sims, ploughed heavy land 5½ inches deep, at the rate of 6¾ acres a-day, for a total estimated cost of about 8s. per acre, which by horse-labour would have been 15s. per acre. On milder soil, 7 inches deep, at the rate of 9½ acres a-day, for about 6s. per acre, which by horses would have been 8s. per acre; and the trenching implement going 12½ inches deep, ploughed at the rate of 5 acres a-day, at say 11s. per acre, work which would need 6 horses for accomplishing only one acre in a day. The saving in the cost of ploughing we may reckon 35 per cent. on the loamy land, 40 per cent. on the heavy land, and say 60 per cent. in trenching; and it is here observable that the economical advantage of steam over horse-power is in proportion to the difficulty of the operation, whether arising from the stubbornness of the ground, or the depth of the tillage. The superior quality of the

work, and the great benefit of turning over the furrow-slices with a rapid motion, and with no damaging pressure either by the plough-soles or by horses' hoofs, were points equally well demonstrated on that as on many other occasions.

The adoption of a shifting engine and windlass, I view as one of the best steps taken for cheapening the operation of steam-ploughing, a step that economizes power, saves time, curtails labour, diminishes wear and tear, and lessens the first cost of machinery and tackle. For working scarifiers and other implements taking a great breadth at once, perhaps it would be well to employ Mr. Smith's removable anchors, instead of the self-shifting one.

Mr. Fowler's latest advance has been to triumph over one of the defects hitherto found in the coiling of the ropes upon the drums. He has dispensed with the man for regulating the winding on, and escaped the wear caused by the grinding and sawing action of the coils of rope upon each other, by giving up winding altogether, and leading the rope round grooves in the drums. He is thus enabled also to keep every portion of the rope sufficiently tight to be held off the ground by the friction-roller barrows, so that the wear is amazingly reduced. The total length of rope is also lessened by one-third, and is now less than half that required for a field of given size by the rectangular method. Only 800 yards of rope are required for ploughing 400 yards' length of furrow, and the price of the entire apparatus for a seven-horse engine is £230. The hands required are only two men and three boys, beside the water-carters. I should also add here, that scarifier tines have been adapted to the plough frame, so that either ploughing or grubbing can be effected by the same implement; and, of course, any traction implement whatever, as, for instance, Mr. Smith's subsoilers or scarifiers, may be worked by the same tackle.

There are many districts in which the fields are generally too precipitous for the easy passage of an ordinary engine from side to side, much less to admit of a locomotive traction engine climbing over all parts of the surface. In such cases we must fall back upon the stationary engine; and we may adopt the direct hauling from a fixed capstan, ropes laid out in a rectangular form, and anchorages self-shifting like Mr. Fowler's, or removed by hand in Mr. Smith's manner, or we may save the wear of wire-rope, and secure a light apparatus, by employing the travelling windlass of the Messrs. Fisken. In this arrangement the wire-rope is fixed, being fastened to self-shifting anchorages at the ends of the work, and the windlass, with implements attached, winds itself along the rope from end to end, motion being communicated from the engine in one corner of the field to the rigger, gear work, and coiling drums on the windlass, by an endless hemp cord mounted upon frames with friction rollers, while, in order that this cord may be very light, it is driven at a high velocity. There are many advantageous points in this invention—the complete control which one man has over the windlass and implements, so as to stop or return at pleasure without signalling of any kind, and the facility with which the tackle can be removed from place to place, being among the number; and it is to be much regretted that we no longer find it in a practical form before the public.

The hemp rope (manufactured so as to be impervious to wet) is so convenient for transmitting power, and I believe not liable to the rapid wearing out that we might suppose, that I will now offer a suggestion for its application in steep districts, where a shifting engine may be inadmissible; and here I would observe, that this paper is intended to be suggestive of mechanical improvements rather than a narrative of the achievements and performances of particular inventions. I believe that ideas are wanted, and beg to submit for your consideration a number of proposals with the diffidence becoming one who propounds methods deduced from theoretical considerations, from observations of the schemes of others tried on a great scale, and from mere working model and garden experiments of his own.

Suppose a windlass mounted on wheels not to travel up and down the field, but simply to shift itself along the headland as required, and hauling an implement by wire-ropes and an anchorage, as in Mr. Fowler's plan. Let there be cutting discs (like those in Mr. Fowler's anchorage), to prevent the windlass from slipping sideways, and let an endless hemp-rope transmit motion to a large grooved rigger on the windlass from a similar one on the engine at one corner of the field. I think a windlass with drums on a horizontal axis would be most compact and simple, and in order to permit of ploughing at various angles to the direction of the headland, the travelling wheels of the windlass frame might be capable of being more or less locked, so that it could advance as it were in an angular or diagonal direction, while the axes of the winding drums still remained at right angles to the line of ploughing. Mr. Fowler's grooved barrels would, however, be still better.

In re-modelling and modernizing this essay, which was written a year ago, I am gratified to find that one of my principal suggestions has now been superseded by Mr. Fowler's simple method of temporarily uniting portable windlasses with an ordinary engine. I will merely state briefly that my proposal was to connect such a shifting and independent windlass as that just described with a portable engine, by means of a beam or bar fastened to the windlass-frame at one end, and to the axle-trees of the engine at the other, provision being made for slightly locking the front wheels of the engine when required for steering. This beam was to be in two parts, with a right and left hand screw for altering its length, so as to regulate the distance of the engine from the windlass, and maintain the proper tension of the driving belt or rope. And the engine might be either shod with the "endless rails," or, more clumsily, travel upon a couple of short planks, laid down before and taken up behind it by hand labour, as in Lord Willoughby d'Eresby's plan.

I will now ask whether we may not relieve the anchorage of most of the present strain, and so have it of the lightest and simplest form, employ much less heavy rope, avoid the delays and hazards of "signalling," and save time at the ends by making the whole operation more automatic than at present. Suppose we give up the to-and-fro work with a single implement, and use two implements, ploughing always one way, namely, up to the windlass, one implement going backward empty while the other is in work. That part of the rope passing round the anchored pulley having only the draught of an implement out of work, and one length of slack rope to haul, may be very light indeed, and the anchorage correspondingly light and portable. No time would be lost in directing the implement into a fresh course, as each implement is steered as it travels backward precisely into the position from which it has to start. Directly one implement arrives at the windlass the other is ready to commence its journey, and perhaps the implement might itself "reverse" the winding drums by coming in contact with a lever connected with the clutches for this purpose, so that the change of motion might be almost instantaneous, and the ploughing perpetual and continuous. When it is considered that we now lose an hour or an hour and a-half in a day in changing, &c., at the ends of the work, the advantage of this plan is obvious. It is most applicable to ploughing in "lands" or "stetches," the track of one implement always the breadth of one bout from that of the

other (as will be presently adverted to); but for flat work, in which the furrows are all thrown one way, crossing of the ropes would occur. This, however, merely requires the slack rope to be lifted over the plough in work, and the plough returning empty to cross over the tight rope. For accommodating the length of the small rope passing round the pulley to the varying lengths of the furrow in different parts of a field, it must be shortened or let out from time to time by means of a few reserve coils carried upon the ploughs. It would be an improvement upon the present mode of hooking the draught ropes to the implement if a "clip" were made use of, which could be instantly released by the ploughman; or if the ropes wrapped round a small barrel, held from rotating by a catch, and allowed to revolve when the pull or draught may be required to be stopped, in consequence of a stone, root, or other obstacle suddenly arresting the progress of the plough.

I now come to the second point—the construction of the plough or ploughing machine. And in the outset I would observe that we require a ploughing *machine*, and not merely a means of yoking separate ploughs held by men as before. When there no longer remain any animals to drive, and we have a steady, uniform, unflagging draught-power, why are we to retain the workman in a mechanical employment, and thus perpetuate our dependence upon his unskilfulness, carelessness, or fatigue? When once relieved from the co-operation of horses, having voluntary movements and wills of their own, ploughing becomes a strictly mechanical operation. The attention and directing judgment of the ploughman are no longer necessary to overrule the animal power, and accommodate the implement to its movements; and therefore I regard as incongruous and objectionable all projects for steam culture with ordinary horse-ploughs held by hand. They are also expensive in labour, requiring more workmen than a ploughing machine does for the same number of furrows; and they are awkward, owing to the difficulty of conducting a succession of ploughs close up to the headland, and turning or shifting them for the return course. Contrivances for meeting this difficulty I cannot but look upon as wasting ingenuity in a wrong direction.

Mr. Williams, Mr. Fowler, and other inventors, have practically demonstrated that several plough-shares and mould-boards united in a single frame may not only make very good work, but also be of considerably lighter draught than single and separate ploughs, taking an equal number of furrows. Not only is the draught less, but power is gained in another way, by combining a considerable number of ploughs together. A rope pulling three ploughs, at a speed of three miles per hour, is dragged twice as far in the same time as a rope hauling six ploughs at 1½ miles per hour; that is, the power wasted in dragging the rope itself is double in the former case what it is in the latter, for the same quantity of work turned over, to say nothing of the double amount of wear. There is also a saving of time. If a three-furrow plough traverse the field in three minutes, and waste one minute at the end, one quarter of the day is sacrificed out of work; whereas, if a six-furrow plough perform the journey in six minutes, the one minute at the end amounts to only one-seventh of the day. Let these considerations be borne in mind, while we proceed to notice various forms of ploughing machine used or proposed.

They are of two kinds—one for flat work, in which the furrows are all thrown one way; and the other for making "lands" or "stetches."

Turnwrest, one-way, or flat ploughing is adapted for light land, and may be practised also upon well-drained strong soils. The most successful steam-ploughs have hitherto been those constructed for this description of work, the advantage attending it being, that an implement, taking three or more furrows at once, can be worked without requiring to be turned round at the ends, and with anchorages gradually shifting along the headlands; whereas in ridge and furrow ploughing such an implement must be moved across to the other side of the "land" or "ridge," and the anchorages shifted a considerable distance forward or backward at every bout; while laying out the slack rope in the next track so far from the plough is also a difficulty. The implement having a simple to-and-fro motion, and the furrows all thrown the same side, it would appear at first sight very easy to fix two or three, or more, of Lowcock's turnwrest ploughs (with shares pointing both ways, and self-adjusting mould-boards) in a frame, after the manner of the common double-furrow plough. But the difficulty is, that the ploughs must change their position sideways at each end of the work, in order to "track" rightly in going opposite ways. Lord Willoughby has displayed great ingenuity in providing for this necessity, but the space required for allowing the ploughs to pass each other places one so far behind another, and time lost in adjusting them is so considerable, that the principle is objectionable. There seems no other course than to have duplicate sets of ploughs pointing in different directions, one carried in the air while the other is in work. Messrs. Fisken attach the ploughs to the ends of their windlass framework, travelling upon two pairs of wheels, one set at each end, and both pointing towards the carriage. The set out of work precedes, while that in work follows the windlass-carriage, the ploughs in each set being just far enough apart to allow the furrow-slices to turn over without danger of choking. Each plough-body is affixed to a separate lever, answering to the common plough-beam, and by very simple mechanism is raised or depressed at pleasure. Thus, instead of the ploughs entering or emerging from the soil simultaneously, they do so in succession, so as to plough square up to the headlands. In the system of direct-hauling by wire-rope, in which it is indispensable to avoid unnecessary mechanism, in order to have the implement as light and simple as possible, we can hardly expect such niceties as this; and, instead of an arrangement of levers, chains, screws, and sockets for lifting and lowering the ploughs individually, I can imagine no better principle than that of balancing two sets of fixed ploughs upon a single pair of wheels, as adopted by Mr. Fowler. The frame, hung midway upon the wheels, with a set of ploughs at each end, is tilted so as to bring the hindmost set into work; and when arrived at the headland, the attendant has simply to pull down the other end, and steer the implement in its next course when the rope begins to move it onward. The two sets of ploughs are immovably fixed upon the framing, pointing toward each other; the wheels, one running in the bottom of the furrow, left open at the last course, the other on the unploughed land, regulate depth and width of work, like the wheels of a horse-plough; and, by means of screws working in vertical standards, the frame can be adjusted upon the axletree, according to the depth of ploughing required. The steerage is accurately effected by slightly "locking" the wheels with a regulating screw, under the command of the ploughman, who rides upon the tail of the frame.

I attach great importance to the saving of time at the ends; and this is one reason for approving of the simple construction and action of Mr. Fowler's plough. One of the main advantages of this implement is the lightness of its draught. From numerous experiments with the dynamometer, it appears that the draught of common horse-ploughs, when out of work, is 30 to 35 per cent. of their draught when ploughing an ordinary furrow. Now, in Mr. Fowler's implement, this sliding of the

weight of the ploughs on the furrow bottom is entirely avoided, the ploughs at one end of the frame balancing those at the other, so that the entire weight is carried upon the large patent-axled travelling wheels. I have tested the draught of the four-furrow plough running empty upon the surface of the land, and found it to be only 3 cwt.; the draught of 472 yards of wire rope dragging along the surface of a clover lea was 3 cwt.; the total draught of implement and rope being no more than that of four common ploughs drawn empty on the same surface. Of course, with the rope supported upon friction rollers, the actual draught is much less.

I would suggest as an improvement, that this plough should be constructed say with two beams of T iron shorter than the present wood beams, and with two diagonally placed beams at each end, made of tubular or angle iron, on which the plough skifes or the scarifying tines may be adjusted by clasps or bolts and screws, for different widths of furrow.

This implement, which, by ready alterations can plough ordinary furrows, trench two furrows deep with effect equal, in dry weather, to that of the spade, break up either whole or ploughed ground by cultivator tines, or pare with broadshare, seems to me just the convertible valuable implement we need in connection with steam-hauling machinery, as this versatility so materially reduces our first outlay.

I now pass on to a consideration of ploughing in lands, ridges, or stetches.

Steam-tillage ought to prove of greatest assistance to the heavy lands, and not only to light lands, which may claim the reaping machine as their gift from the mechanic, it being specially adapted to their upstanding crops; and from the restricted area of permanent subsoil-drainage yet in existence, as well as other circumstances, the great majority of farms on our strong wheat-soils are undoubtedly ploughed, and I fear must for many years be ploughed, in ridge-and-furrow "lands."

It would be possible to form a land with Mr. Fowler's plough, first going two courses (that is, once up and down the field) on one side of the ridge, and then, with considerable loss of time, turning the plough end for end, and going two courses to complete the other side; but, still better, the ploughs at one end of the frame might be left-hand, and the other right-hand ploughs, the implement then not being turned round. The slack or return ply of the rope following the plough would have to be laid out sometimes half a land's breadth aside from the track, and a guide wheel running along the last open furrow would be necessary to regulate the parallel distance of the next ridge. The anchorage, I think, would simply need to be shifted half a land's breadth at a time. But there is one objection. When we consider that one of the chief points of good ploughing is to form the sectional contour of the land in a proper curve, so that every furrow-slice shall be lower in regular gradation as we recede from the ridge (in order that the harrow edges of all may be equally prominent); and when we remember that a skilful ploughman secures this form by adjusting the width, depth, &c., of each furrow according to its distance from and relation to the ridge or water furrow, and according to the previous shape of the ground, we perceive that no implement ploughing all its furrows one unvarying depth and breadth can be well calculated for this description of work. Perhaps Mr. Fowler may improve his ploughing-machine for stetch work, by giving the workman power to alter the depth of either side of the frame without stopping for the purpose.

Mr. Williams suspends his single set of ploughs upon levers capable of working vertically in a carriage-frame, each plough being independently raised or lowered, but the machine has to be turned round at each end of the work at every course, and taken across to the other side of the land—a difficulty which I believe Mr. Williams has not yet overcome without the use of horses—and the alterations of depth, &c., necessary for different courses, must occasion considerable delay. But it is unnecessary for each plough to have a "swimming" motion independent of the rest. There appears to be no practical obstacle to the employment of a considerable number of ploughs rigidly fixed in a frame, but, on the contrary, the lightness of framing and adjustments in proportion to the breadth of ground operated upon (so important in lessening the load to be drawn) is in favour of such an arrangement. We might take half a "land" at a time, if the machine would not be too cumbrous, so that when the ploughs are once "set" (with regulating screws, &c.) to their proper depth and position, according to the form of the surface to be ploughed, no alteration whatever would be necessary. But a frame of six or seven ploughs following each other would be too long and unwieldly; therefore, let us turn half the furrows one way and half the other, the ploughs being in two sets, placed abreast, instead of following one another. The six ploughs will thus occupy only the same length of frame as three; the machine, indeed, with wheels in front and behind, will be of much the same dimensions as a scarifer. Mr. Coleman exhibited at Chelmsford a ploughing machine of this description, in which the ploughs were arranged in a V form, like a flock of wild-fowl. Suppose we attach the ploughs to the bars or beams of the framework by a fastening somewhat similar to that of Bentall's broadsharer, so that they can be adjusted to different depths and widths, according as the ground may be level or in ridge and furrow. By raising the fore-end of the frame upon its carriage wheels (with a wheel-and-screw or lever movement), the ploughs are run out of work of their own accord, and by depressing the front they are pointed in. Let there be two implements, ploughing only up to the windlass — in accordance with the method of hauling, described in a previous part of this paper. One is to "gather," or turn its furrows inwards, forming a ridge in the middle; the other is to "split," throwing its furrows outwards, leaving an open water-furrow in the middle; that is, the first implement makes "ridges," or "feerings," of a certain distance apart, and the other "makes up" the intervals, forming complete lands or stetches. Carriage wheels follow in the last furrows to sustain the weight of the implements, and for them to travel upon as they run backwards out of work. The manner in which the two implements would be worked, with a minimum of time lost at the ends, and a saving of power in several respects, has been already sufficiently described. I need merely refer now to the advantages of making the ploughs in each frame turn half their work opposite ways, and to the possibility of lightening the draught by avoiding sledging and sliding action as much as possible.

From numerous dynamometric experiments, it appears that in a heavy soil, if the whole draught of a plough in work be taken as 100, then, with the mould-board removed, it will be 90, drawn along an empty furrow it will be no less than 35, leaving 55 to represent the power required for cutting the slice. Much of the 35 per cent. may be saved by supporting the implement upon three or else four carriage-wheels, and shortening the sole as far as it can be done without causing the share to make a ragged uneven furrow-bottom. The 10 per cent. due to the action of the mould-board may also be reduced; for though the weight and friction of the soil upon the upper surface of the mould will remain, the weight lifted (several stones) may be mainly sustained by the travelling-wheels, instead of borne by the sledge formed of the sole and the heel of the mould-

board. The 55 per cent. due to the operation of the share and coulter must not be supposed to arise merely from the dividing of the soil by their cutting edges; the share has a considerable weight of earth resting upon it, not only occasioning great friction upon the upper surface of the share (which cannot be obviated), but greatly adding to the pressure and friction of the under-side of the share upon the furrow-bottom. By forming the ploughs in our machine so that no part shall touch the furrow-bottom, except a small portion of the share-edges and soles, and by bearing the entire weight upon wheels of considerable diameter and broad peripheries—or, perhaps, applying the "endless-rails" to prevent sinking—a very large proportion of the friction, cohesion, &c., of the horse-plough may be dispensed with. There is also another consideration. A common plough exerts a great side-pressure against the upright land-side of the furrow, owing partly to the reaction of the furrow-slice in turning over sideways, but principally occasioned by the diagonal direction of the share's cut. If the cutting-edge of the share make an angle of forty-five degrees with the direction of the plough's advance, there will be a pressure against the side of the furrow equal to that needed to overcome the resistance directly in front of the share. But when we fix two sets of ploughs in a frame, half having right hand, and half left hand shares, instead of any side-thrusts being taken with a sliding action upon the face of the furrow, the side-pressures of all the ploughs neutralize each other. By proper attention to these points, I conceive that an economy of power would result.

I have not time to detail the simple steerage by slightly locking the axle of the front wheels, the adjusting of the hind wheels to make them act partially as "soles" to the ploughs, or the short coil of reserve rope and the clip by which it is held. I need merely add that all the arrangements might be very simple, and that the implements would travel with their wheels partly running on the unploughed ground, but chiefly along the smooth and clean furrow-bottoms, and only for an instant cross over the ploughed land. Of course the draught of a large implement taking six furrows at once must be heavy, but the load is sustained by the windlass and not by the anchorage. Perhaps the chief objection is the difficulty of making furrows of equable depth on uneven land by an implement of such great width.

Having now concluded my review of the subject of steam-ploughing properly so-called, and offered various suggestions for its better accomplishment, I must briefly allude to

New Processes, Rotary Forking and Digging.

First. *Implements operating by Traction.*—Mr. Smith, of Woolston, is very successfully carrying out a novel system of tillage, by means of trenching, subsoiling, and grubbing implements, without using the common plough except for turning over clover lea and sward land, and this, indeed, he thinks to be hardly necessary. He combines subsoiling tines with the double mould-board plough, and follows with the single subsoiler, so that the land is left ploughed up in "drills" or "ridges," the subsoil at the bottom of the open furrows and trenches broken up and exposed to the atmosphere, while the strips of ground covered by the upturned furrow-slices are also stirred and disintegrated. On all soils that are not thin or light, this must be a remarkably effectual fallow process; the partial inversion and complete stirring exposing such a large proportion of the staple and subsoil to atmospheric action. The subsoiling tines are exceedingly efficient, somewhat resembling spades, or square fluked anchors, in shape, and so sloped as not only to enter and pulverize deeply the entire breadth of a furrow each, but also to raise a considerable portion of the subsoil for admixture with the upper staple. And the various cultivators used (manufactured by Messrs. Howard, of Bedford) are remarkably simple, strong, and effective, and possess very admirable contrivances for steering, raising and lowering, and turning round. My paper being confined to mechanical methods of applying steam-power to tillage, rather than referring to tillage itself, I say no more here, except that Mr. Smith's land and crops testify to the soundness and value of his husbandry upon very heavy and also upon some other qualities of land; and his experience, fortified by that of various agriculturists, shows that there is economy in expeditiously breaking up ground by these implements at a total expense of 6s. 6d. to 10s. per acre.

We have been long familiar with the revolving harrow, forker, or scarifier, as brought before the public by Mr. Gibson, of Newcastle-upon-Tyne, Mr. Samuelson, of Banbury, and other inventors. And I believe the decision of practical judges respecting them to be that, while they may be admirable in certain cases for stirring ground already tilled, they are not able properly to break up and invert unploughed land. However, I do not quite despair of this form of digger for effecting the first and principal operation of tillage. Mr. Smith, of Lois-Weedon, has contrived an implement of this kind which answers perfectly well for pulverizing and lifting up the subsoil from the bottom of the trenches previously ploughed along his "intervals," casting the furrow-slices of staple underneath, and depositing the subsoil upon the top. The tines (of proper cycloidal curve), instead of being arranged upon separate discs, forming a set of independently-revolving rowels, are all fixed upon one barrel; as the machine advances, the earth is crumbled and raised bodily by the teeth, and while it hangs momentarily suspended in air before being cast off by fixed scrapers, a couple of small mould-boards gather the upper soil (previously turned by a plough) on each side into the bottom of the trench, the earth from the digger falling upon it.

Could not a simple implement of this character be made for ordinary husbandry, in which the whole surface has to be cultivated? Suppose a similar digging cylinder or wheel, to take only the width of a common furrow, preceded by a couple of skim-coulters or small ploughs, that would pare the stubble or sward, and cast it into the furrow left open at the previous course; then the earth raised by the digger might be diverted as it fell by a sloping mould-board, and laid upon the top of the thin slice deposited by the skim-coulters. In this way a perfect inversion and burying of the surface would be secured, while at the same time there would be a thorough comminution of the soil, and no pressure or sledging upon the furrow bottom. I think the draught of such an implement would be comparatively light, as the weight would all be supported upon the axis of the digging-wheel, and help to force the tines into the ground. The implement would also be very convertible; for, by taking off the mould-board we should have a rotary subsoiler instead of a trencher, the soil being mixed instead of inverted; and by adding other digging-barrels on each side, we might have a wide grubber or cultivator. For the purpose first mentioned—that of ploughing or trenching better than the plough—perhaps it would be equally efficient with the combined implement, proposed I believe by Mr. Fowler, in which a furrow-slice is ploughed the full depth, turned precisely upside-down, and then broken by the points of Norwegian-harrow rowells following upon it.

Hanson's potato forker is another form of rotating pulverizer. Could not Mr. Fowler apply the revolving blades or tines to cut the furrow slices of his plough crosswise? Motion might be derived from one of the

travelling wheels, and thus ploughing and pulverizing would be accomplished in a single act.

Leaving now the traction principle altogether, which, in the case both of ploughing and scarifying by steam must be now pronounced fully successful, let us inquire into the merits of

Machines actuated independently of Traction.

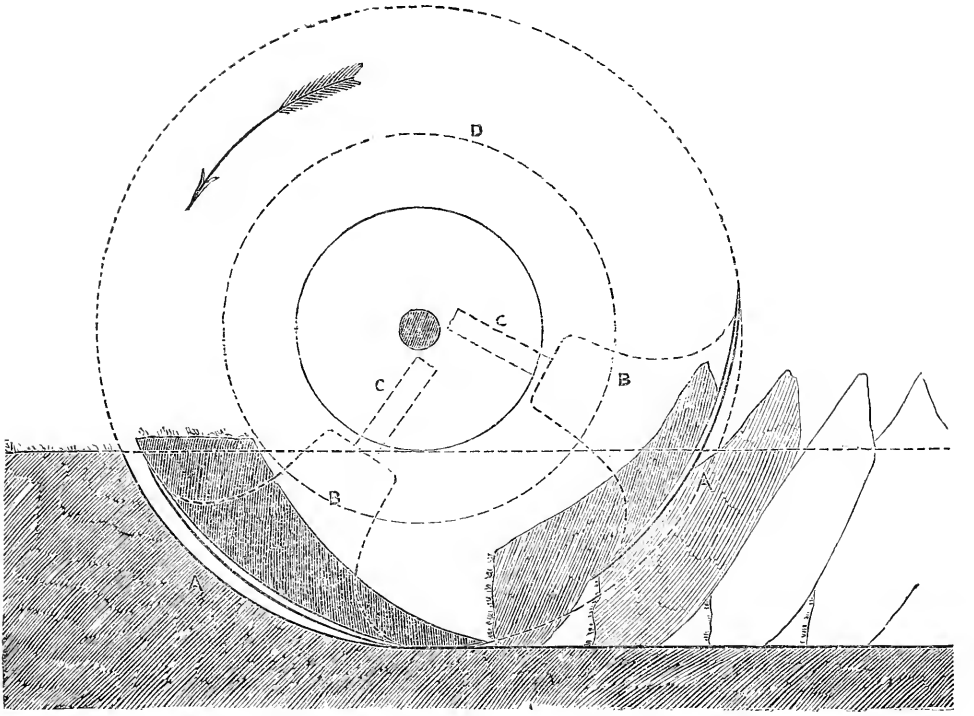
I dismiss without notice multitudinous contrivances for imitating the motions of manual digging, partly because they would demand more space than I feel at liberty to devote to them, and partly because I prefer, for simplicity and practicable character, machines having a continuous circular motion and few working parts; and indeed, I believe, that ultimately the highest order of results which steam-culture will ever attain, will be by a revolving tiller, because, theoretically, it is best adapted to the new motive-power.

The idea of Mr. Hoskyns, that a cylinder of claws, tines, or cutters, should be attached behind a locomotive engine, and driven at a more or less rapid speed by the motive-power, notwithstanding the success of steam-traction implements, never promised better than it does now. I do not know what has become of Mr. John Bethell's revolving forker, but, at any rate, Mr. Romaine's machine in the hands of Mr. Alfred Crosskill has at last achieved considerable success, the velocity of the digger, however, being greatly moderated from that originally proposed. A rapidly revolving scratching tool may serve for superficial slicing and mincing as a substitute for paring; but in order to invert the soil completely, and perform the best kind of work required by the farmer in deep culture (for which digging machines seem most suited), I am of opinion that the soil must be cut or broken into pieces of sufficient bulk to be turned bodily upside down, and these must not be left to fall at hazard in any posture, but laid in their proper position by the machine, in order to make perfect work. This operation necessitates a slow rather than a quick rotation of the cutters; accordingly Mr. Usher's rotary steam-plough, in which a series of curved plough bodies are attached about a horizontal axis driven by gear work, behind a locomotive engine, was a near approach to what we required, and had the tilling machinery been combined with a modification of the endless railway engine, or the difficulty of locomotion been otherwise better overcome, this invention would probably have given us a cheap, though not very perfect, order of tillage. But Mr. Romaine's cultivator is a decided success. A digging-cylinder, 6 feet wide, is attached behind a twelve-horse engine, mounted on a pair of very large broad felloed wheels, with two steerage-wheels on castors in front. The machine is perfectly independent of horses for travelling from place to place over moderately level roads or arable fields, though its weight is 10 tons, and it will turn short round, or in an area of its own length. Parallel connecting-rods, like those coupling the wheels of a railway locomotive, are used for driving the digger with a speed of forty to fifty revolutions per minute, allowing it to be readily raised or lowered while in motion. The cutters, fastened by bolts and screws upon the plate-iron cylinder, resemble scarifier paring-shares in form, and, as the engine slowly advances, slice and dig up the soil from either 3 or 4 inches to 10 inches deep, as required. Having seen the work done, I can bear witness that tenacious soil is thoroughly broken up and subdivided, the surface-stubble, &c., buried sufficiently well, and the subsoil largely upturned and intermingled with the top staple—in fact, the work has much the appearance of that of the digging-fork. The successive operations of ploughing, dragging, and harrowing strong land are equalled by a single course of this machine, and at far cheaper cost, the amount of work done being from four to seven acres a-day, according to the description of soil and depth of work, at an expense of 5s. or 6s., up to 9s. or 10s. per acre. The price, I believe, is about £800. It is a matter for experience to determine how far the weight may prove injuriously consolidating on stiff clays, and whether the farmer can keep in order so many wheels, running bearings, and working-parts. The cultivating cylinder, however, promises to become all that the farmer requires; only, for working on ground already ploughed or cultivated, on hilly fields, and on wet clay soils, I hope means will be found to actuate it by ropes from a shifting or stationary engine.

In searching out and studying all the proposals I can meet with for digging or deeply trenching, I have concluded that the simplest, easiest, and most practicable idea, is that of a cutting-blade attached by an arm or stem to a horizontal axis, and curved concentrically, or nearly so, with the circle it describes, which entering the soil downwards, shall cut a curved spit of earth from the face of the semicircular trench formed by its action, and emerging upwards on the other side of the trench, leave the spit in an inverted position, as represented in the annexed woodcut.

A number of these cutters are to be affixed by radial arms to the shaft, but in order that they may not impede the delivery of the pieces of soil from each other, I propose that they should be placed at an angle with the plane of the circle they describe, and let the machine advance at right angles to the direction of their revolution, the axis being longitudinal instead of transverse, just as in Hanson's potato digger, and Huckvale's turnip thinner. The digging-disc (supported and actuated in a way to be presently noticed,) proceeds sideways, as it were, along the trench, slicing off spits from the face or edge as a workman does with a spade, and carrying and leaving them on the opposite side inverted and turned end for end. The arm or bracket to which each cutting blade is attached acts as a coulter to divide the portion to be cut. Suppose the blades to be of 9 inches breadth, then one blade must enter the ground for every 9 inches travelled by the machine; and with six cutters following one another (somewhat after the manner of the knives in Gardner's turnip slicer) the revolutions per minute will be only 29, for a progression of 1½ miles per hour. The "bite" or thickness of the spit may be, say 7 inches, when the depth is a foot; thus, for a single digging disc, the extent of land dug would be at the rate of one and 1·5th acres per day; but, of course, I propose to have several diggers on the same shaft. Working at less depth, the speed might be increased. For going 12 or even 15 inches deep, the disc need not be of greater diameter than say three, or at most four feet. And it is to be noted, that though of small diameter, as the digger works always in the trench, a spur-wheel of considerable size may be hung on the same shaft to drive it. I propose that the machine should traverse up and down the field, without turning at the ends, the digging disc always remaining in the trench and revolving the same way. The only change necessary is to point the cutting blades at a different angle when the machine is to travel the reverse way; and this is done by setting each arm or stem in a socket, and connecting the six arms so that they are turned round simultaneously. The blades are double-edged, in order that they may be turned round so as to bring the arms into operation as coulters, whichever way the machine may be moving. But the form of cutter proposed is also adapted for revolving upon a transverse shaft or cylinder like Romaine's.

Motion may be communicated to the digging-wheel in several ways. It may be affixed to a locomotive engine. But I should prefer to drive it by an endless



A A Position of digging-blades on entering and on rising out of the soil, cutting a spit say 8 inches thick and 9 inches wide, with the trench 15 inches deep.

B B The stems or arms supporting the blades are sharp at their edges, so as to act as coulters, for severing the side of the spit from the whole ground. The blades are set diagonally across the plane of the circle there described, so as not to track after each other; and are turned round in sockets C C, when required to point the other way, for the return course.

D Size of the wheel by which the digger is driven.

rope, supported upon friction rollers, in connexion with a stationary engine, or an engine shifted along one end of the field—a modification, in fact, of Mr. Atkins' and Messrs. Fisken's method. For a single digging-disc, perhaps there would not be too great a resistance to be driven by wheel-work from the travelling-wheels of the carriage-frame, on the principle of Hanson's potato-digger: the wheel having teeth or cogs upon its felloe to give it a firm hold of the ground, might travel along the bottom of the trench, and so partially operate also as a sub-pulverizer, breaking up the hard bottom; and as the digging-disc is adapted to a pace of two miles per hour, horses might work it if required. I would suggest, however, that in case the bite and resistance thus obtained were found insufficient for very deep work, a couple of wire-ropes wound upon the drums of the machine, and fastened down at both ends of the field by shifting anchors, would cause the drums and connected gear-work to revolve by the simple advance of the machine; though this travelling windlass would involve considerable weight and complexity.

My description of this rotary digger is very general and devoid of details, the rather rude drawings accompanying this paper merely giving some idea of the circular cutting and inverting of a movement I advocate, and, in fact, it is not the particular form, but the distinctive principle of action involved, that I wish to bring before you.

In conclusion, let me hope that at least some of my suggestions with respect to working traction implements by steam-power, and the construction of new tillage machines, will prove useful to some gentlemen who may be practically grappling with the mechanical difficulties in the field, and that the principle I have introduced to your notice for deep-digging and perfectly inverting the soil, with the least possible waste of power in raising the cut pieces, will meet with your consideration and approval.

On the conclusion of Mr. Clarke's paper the Secretary read the following letter:

Sir,—In the *Journal* of this Society for February, 1856, are a few remarks I then made on the subject of ploughing or land cultivation by steam-power. These impressions were arrived at, and forced upon my mind by the importance of the subject, and by frequently witnessing the various methods (ingenious and persevering) by which the desideratum was sought to be accomplished. I would now frankly have renounced my ideas, and cordially have congratulated any inventor who had, by this time, made the progress then hoped for, and which their great efforts have really deserved; but feeling, as I do, that so little improvement has been made in the art by any of the methods during these two years, I am more convinced we are not yet in the right path to the possession of an implement such as would generally supersede the good horse plough, and which the enterprising agriculturist would hail with pleasure and readily adopt. Sincerely feeling, as I do, how very ungenerous and hard it may seem to these energetic pioneers to dwell on their unrewarded efforts, I would gladly adopt any course of remarks or argument which would avoid allusion to a failure or touch a disappointed hope, and would therefore briefly state that from all I have yet seen or heard of improvements and trials of the now existing means, I am forced back to the conclusion I had arrived at in February,

1856, that the thorough and practical steam cultivator is to be wrought out of such a construction of machine as I then sketched. It may with seeming justice be asked, why I disapprove of all existing plans, and still do not produce my own idea in a competitive form. My answer is, that during these years I have, through impaired health, been compelled to relinquish, in a great measure, the practical management of our somewhat large manufacturing business, and those left to do so find their heads and hands full enough in grappling with the large and small details of works requiring increasing attention.

The machine I had sketched in 1856 I still think well worth the consideration of one or more possessing the ability and bold determination of some of the gentlemen I have alluded to; and should success be theirs, I will be satisfied with that which is only due to me, for having pointed to the outline of an implement for so desirable an object. I would very shortly repeat that the machine I proposed was in the form of a portable engine, not much exceeding in weight and size that now used to work a combined thrashing machine; the addition and difference would consist in a frame containing a number of digging spades, and the application of the engine's power to the up and downward motion of the spades and turning over the pieces of soil they lifted, much in the same way as a man does with a spade. I think I may fearlessly assert that no plough has ever equalled the spade in the beneficial results to the soil and its productions; the expense and insurmountable difficulty of having the work done within the necessary time by men being the objections; and, if so, then the implement we really require is some twenty or more spades worked by the uncomplaining giant steam, so obedient and untiring. The arrangement of the spades, and their required motion, are not insurmountable difficulties in the science of mechanics, while the engine's weight, instead of being a drawback as at present, would be the intermediate power by which I would force the spades into the ground, and these spades would act as so many levers, by which the machine would be moved step by step. No space, whether the field was large or small, would be left untilled any more than in the case of the best ploughing, and the digging would be deep or shallow at the option of the attendant, or as the frame had been set for him. No power would be misspent; the whole apparatus would be as free from derangement as the portable engine and thrashing machine now are, and quite as portable; for when the work was done, the spade frame would either be lifted clear of the ground, or disengaged, and the travelling wheels left free for locomotion. In common with so many, I long to see an efficient machine for such a great work; and if my ideas should now fall into genial soil, my object is served. I am, &c.,

RICHARD GARRETT.

Leiston Works, Saxmundham.

The CHAIRMAN said this was a most important subject, for he thought we were in a state of transition as regarded the cultivation of the soil. He had no doubt that, in process of time, the ingenuity of this and other countries combined would bring steam-ploughing, as well as reaping by machinery, into general use. More attention was required to the machine itself than to the engine which was to work it; the latter might be considered as having been brought almost to a state of perfection. He had an opportunity, at the Paris Exhibition, of witnessing the operations of from twelve to fifteen different steam reaping-machines, and he had reported upon them to the Government of this country. Throughout those experiments, it struck him very forcibly that more was wanted from the farmer than from the engineer, inasmuch as a great deal depended upon the land being brought into a state fit for the application of machinery. Until attention was paid by the farmer to this point, it was in vain for engineers and inventors to bring forward machinery for the cultivation of the soil. It appeared to him that, in good cultivation, the first step was to carry off the surplus water by a complete system of drainage, to increase the depth of the staple, and to bring to the surface portions of the subsoil. He believed, if those necessary preliminaries were carried out, they might apply machinery to the cultivation of the soil with good effect, and at a cost which would be within the means, not only of the gentleman-agriculturist, but also of the tenant-farmer. He saw many practical men present, and would be happy to hear their observations on this highly interesting subject.

Mr. J. J. MECHI was of opinion that steam-cultivation would, ere long, become the custom of the country. He would mention that two years ago Mr. John Fowler ploughed a quantity of land for him, and he could assure them of the marked superiority of the crops on the land so treated, as compared with that subjected to the ordinary horse-ploughing. There was a difference in the crop of wheat, of at least a quarter per acre in favour of ploughing by steam. The superiority was apparent from the first appearance of the crop, and was maintained up to the time of harvest. The depth to which the land was ploughed was considerable, and, in addition to this, subsoil ploughing was also employed. The work was allowed, even by the labourers, to have been done with much greater regularity than could be effected by horse-ploughing, and fresh soil was brought to the surface which had never before been disturbed by any implement. It was true the work was done some little time before the crop was sown, and no doubt the action of the air upon the raw subsoil was very beneficial. He thought they would all agree as to the superiority of steam over horse-power, wherever it could be brought to bear. An acre of ploughing per day was considered fair horse-work, and that would be done by 2 o'clock in the afternoon, at which time the horses returned to the stables, and remained there eating and sleeping till 6 o'clock the next morning. In the summer months especially, an immense amount of time was thus wasted, and the horses must be kept and fed whether they worked or not; so that all experience tended to show that horse-power in the cultivation of land was but a make-shift, and must, he thought, ultimately succumb to mechanical contrivances. His impression, some years ago, was that Romaine's engine would be very effective, and he had spent some £700 in experiments with that machine. Since then he believed £10,000 had been expended in experiments, and with very important results. He had no doubt larger sums yet must be spent before they arrived at perfection, and every year would witness large improvements in the application of steam machinery to the purposes of agriculture, as was the case with regard to manufactures. He hoped the farmers of the country would be sufficiently alive to the importance of adopting these appliances when they were offered to them. It was certainly not the duty of the tenant farmers to lay out their money in making these experiments, but at the same time they ought to be willing to pay a fair remuneration to those who afforded them the means of carrying on superior cultivation at a cheaper rate. By the facilities of inter-communication afforded by railways, many local prejudices had been abolished, and districts which formerly prided themselves that they were in the van in agricultural matters, discovered how much they were behindhand. After all, depth of cultivation after good draining was the true manure. Let the subsoil be brought into contact with the air, and they would find a treasure which had never before been developed. He had every year increased the depth of cultivation on his land, and had always been rewarded for it. Recently he had a field dug all over with the steel digging-fork, and he had found it more economical in its results than ploughing with horses. There were five horses ploughing in one field, and in another field four men fork-digging, and he found the latter cheaper at £2 per acre, the men earning 2s. 6d. per day, than the work of five horses and two men in ordinary ploughing. The more he saw of horse-power, the more convinced he was that it was the worst and most costly power that could be employed, but at present the use of it was unavoidable.

Mr. J. ALLAN RANSOME said, that the very able paper they had heard was certainly a most accurate record of all that had been done in the application of steam machinery to agricultural purposes up to the present time, and many of the suggestions put forth, he felt, were extremely valuable. On the two previous occasions on which he had attended discussions on this subject, practical progress in this direction had been shown to be extremely limited. With the exception of a little work carried on in one season on Mr. Smith's farm, nothing had been practically done when the subject was first discussed in that room—at least so as to induce others to follow in the same steps. Since that time great improvements had taken place in the three leading plans referred to in this paper, namely, first the locomotive traction engine drawing an implement after it; secondly, the steam-engine employed to give motion to rotary machinery; and thirdly, the employment of traction ropes with a fixed engine. He had already

expressed an opinion in favour of traction by means of stationary engines. His attention had been principally directed to the latter system, from the belief he entertained that the best practical results would be derived from it. Looking at the results of Fowler's method of steam-ploughing, it had up to the present time been found very effective. This was shown by the fact of a twelve-horse engine working five ploughs during the week, at the rate of an acre per hour. To accomplish the same work with horse-power, would take sixteen horses. The number of men in the one case was five, and in the other eight. In the one case they must be all skilled ploughmen; whilst in the other they required only one person competent to drive an engine, another able to guide the ploughs, and the remainder could be done by boys. It was further to be remarked that, during the necessary period of rest and feeding both for men and horses, the steam engine might be employed in other operations on the farm. He would now speak of another class of implements. The plough was universally admitted to be inferior to the spade. Why was that so? There must be some detrimental effects produced in ploughing which must be set against the good done to the land. In the first place, there was the treading of the horses' feet; and, in the next place, the hardening of the soil by the action of the broad bottom of the plough. He regarded the implement which had a tendency to break up and comminute the soil as the nearest approach to perfection; and where the steam plough had been introduced, with the avoidance of friction, and where the soil was broken up by an implement following in the wake of the plough, he believed it was quite equal to the process of digging; and he thought this might be effected by the traction rope and fixed engine. At the same time, he thought that a lighter description of engine might be adopted, which could be used as a rotary travelling engine. But, whilst there was work sufficient for each manufacturer in his individual line, he thought ploughing by traction had been almost brought to perfection; but, with regard to a thoroughly practical digging machine, he feared that the probability of success was rather remote. The necessary complication of such a machine would stand in the way of its success. He lamented as much as any one that the state of his friend Mr. Garrett's health had delayed his further progress in that direction, but his friends might console themselves that he had thus been released from a matter which would certainly have occasioned him a great deal of anxiety; and in the event of Mr. Garrett's restoration to health, he (Mr. Ransome) would advise him not to expend his energies upon the invention of a digging implement to be worked by steam.

Mr. J. J. Mechi mentioned, as a proof that Fowler's method of ploughing was coming largely into use, that a contract was taken for ploughing 200 acres by this plan on a farm in Essex. This showed that it was in large practical operation, and he had no doubt that it would answer.

Mr. Newton, although not a practical agriculturist, would venture to differ from some of the views expressed by Mr. Ransome. He did not think ploughing—taking the plough in the form in which they were acquainted with it—could be beneficially carried out to any great extent in this country by means of traction power. Whether the implement was capable of modification, so as to obviate the hard under surface occasioned by the sole of the plough, he could not say. Every agriculturist would admit that ploughing was not so beneficial an operation in the preparation of the land as hand labour with the spade, but this was so expensive as to be out of the question. He thought the application of traction by ropes to the plough involved great waste of power, and the friction of the rope on the ground occasioned an amount of wear and tear which formed a serious item of expense. Nor was that the only objection to ploughing by steam under the method adopted by Mr. Fowler. There must be great waste of time, especially in small fields of six or seven acres, in arranging the anchors and windlass, and also in the lateral shifting on the headland. It was stated in the paper in some instances to occupy 25 per cent. of time throughout the whole of the day. That formed a serious item. If they had large fields, such as were seen on the continent, the case might be different, and in fields of 100 or 150 acres Mr. Fowler's plan could probably be carried out with advantage. They must, however, take the case as it stood in this country. They could not remodel estates.

Mr. Mechi said this must be done.

Mr. Newton very much questioned whether the landlords as a body would allow their tenants to grub up the hedges, and cut down the trees, to form open lands on their farms. Reference had been made to Romaine's cultivator. That machine could be taken to any field where the gateway was wide enough to admit it, and every foot of the land could be cultivated by it, without any further operation being required; besides which, it was capable of being adapted to all the purposes for which the portable steam-engine was employed upon a farm. The cost of that machine was stated in the paper to be £700. It ought, however, to be borne in mind, that an implement of that kind dispensed with a considerable amount of horse-power. He believed it was not generally known that the horse-power for agricultural purposes in this country consumed from one-fifth to one-sixth of the whole produce of the land.

Mr. Mechi said, on small and moderately cultivated farms it would amount to one-fourth. On well-cultivated lands it would be about one-fifth.

Mr. Newton added that such an item in the expenditure on a farm was very serious. He repeated his belief that the system introduced by Romaine would ultimately be found to be most successful in the cultivation of the land, from the fact that all the necessary operations were effected at once.

Mr. Mechi wished to explain, that in stating the consumption of the horses on a farm to be, in some cases, one-fourth of the produce, he did not mean one-fourth in value, as of course horses were not fed upon wheat, but the produce arising from one-fourth of the extent of the farm.

Mr. John Fowler had listened with great interest to the able paper of Mr. Clarke, which he regarded as a most excellent *resume* of what had been effected in steam culture up to the present period, and an extremely fair criticism upon the merits of each invention. With reference to the remarks of Mr. Newton, although he agreed with him in the belief that rotary cultivation in some shape or other would be ultimately brought to bear, yet they could hardly assume that it would do all that was required. It was possible that rotary cultivation might effect the overturning of the soil, and he believed there was no very great difficulty in bringing it to bear for that purpose on level and firm soils, but upon very uneven surfaces the power expended in taking the machine over them must be very great. Of course there were many improvements in detail which might be made in such a machine; and he should be glad to see the gentlemen-agriculturists of England, for it was not the place of the tenant farmers to do it, appropriating a small portion of the income which they derived from the land to experiments in rotary cultivation. With regard to himself, he ventured to say that the system of ploughing he had introduced was a step in the right direction. He thought there could be no question that it was a really practical plan, inasmuch as it performed the ploughing at half the cost of horse-power, and the work was better done. He was happy to have the testimony of Mr. Mechi in its favour, though it was by no means the first he had had. Seven acres of sandy soil, in the neighbourhood of Ipswich, had been ploughed by steam, and the result was, even on land which had no rich subsoil to be turned up, that a yield of a quarter per acre more in the crop was obtained. The people in the neighbourhood suggested that the difference arose from the depth of the tillage having prevented the drought from attacking the wheat. He admitted the superiority of hand-spade cultivation over even steam ploughing, but it was too expensive in practice, and he was prepared to say that, on heavy clay land, steam cultivation, equal to spade labour, could be done for 12s. an acre. With regard to the wear and tear of the rope under his system, a misapprehension existed. Upon clay land he would guarantee the wear of the rope at sixpence per acre; he believed it would not exceed threepence per acre; but if the work was done upon gravelly soil abounding with sharp flint stones, greater care was necessary with regard to the rope, although in such cases he believed the expense would not be greater; but if farmers used the rope in the careless manner they frequently did their steam engines, of course they must be content to bear the expense of their negligence. Judging

of what he had seen of rotary cultivators, he believed that they would occupy a prominent position in a few years, and no pains should be spared to bring this about. There was one point which bore materially upon steam cultivation. The moment they were prepared to do all the cultivation on a farm by means of machinery more advantageously than by horse-power, horses themselves would only be required for the carting, and would have to stand idle a large portion of the week. This showed the importance of bringing about a perfect system of steam traction. Mr. Boydell had gone far to develop that. He (Mr. Fowler) believed that a smaller class of that description of engine—say, of four-horse power—could be used for the work of a farm more economically than horses. He thought it ought to be fairly tried. Who was to try all those experiments? Were the inventors to bear the whole brunt of that which was in fact a national benefit? The landlords hitherto had done little. The Royal Agricultural Society had given no help. He could only state that the trial of his system at Salisbury was appointed to take place on a steep hill, resembling the roof of a house, and the decision arrived at was, that the steam plough would not answer. Notwithstanding all this, he was prepared to prove that he could plough at half the cost of horse power. It was plain they would get no assistance from the public or from the landed proprietors, who would, after all, derive the greatest benefits in the improved rental of their estates. As far as steam ploughing was concerned, he considered his task was done; but it was for such men as Messrs. Romaine and Boydell to carry their experiments further in another direction, and he was strongly of opinion that the public at large ought to help them in their work.

Mr. SMITH (of Woolston) avowed his determination not to receive any assistance from any society or any individual. He would state his reasons for not using the combined plough for the inversion of the soil. In January, 1856,* he stated before this Society what he had done in the way of steam tillage up to that period, and he would now state what he done further since that period. He would not speak of his own plough, but would refer to the machinery employed for laying out the land, and the mode in which he effected it, as upon that he considered the success of his system of tillage mainly depended. In the two experiments referred to by Mr. Clarke in his paper, one at Chelmsford and the other at Woolston, he (Mr. Smith) had not space enough to show properly how he set out his work. Mr. Smith proceeded to explain the details of his plan, particularly describing the mode of setting out his machinery and tackle. (This, however, would be unintelligible without the plans and sketches to which he referred.) Mr. Smith went on to remark, with reference to steam culture, that all farmers would admit that the first month after harvest was worth all the other months of the year put together. There were, in fact, only two months which were really valuable to the farmer for ploughing. Those were Sept. and October. The engine which he recommended was the common eight-horse engine, but he had found a seven-horse engine sufficient for all his work, upon a farm of about 200 acres, 110 of which were arable; and the engine could do all the thrashing, grinding, cutting, &c. The tackle to be attached to it, he contended, was paid for in the first season it was used. He had found in his own experience and that of his brother-farmers, that a quarter per acre more in the yield of the crops resulted from his system. Mr. Smith next proceeded to contrast the system of anchorage and rope traction adopted by Mr. Fowler with his own plan, and pointed out the important reduction he had made in the number of horses he had employed previously to the introduction of his system of steam cultivation. In the first year he steam-ploughed a field twice over; and the yield was 41 bushels of peas per acre. The succeeding crop was barley; and the yield of that was 7 qrs. 1 bushel per acre, from land which formerly only gave a yield of 5 qrs. per acre. Upon an average, he employed his steam machinery in culture 39 days in the year, consuming 14½ tons of coal, at a cost of £14 10s. The only additional cost was in increased labour; for during that period he had allowed his men sixpence a day extra. Mr. Smith then read letters from Mr. Randell, of Chadbury, near Evesham; Mr. Bright, of Teddesley; Mr. J. Whiting, of Stoke Goldington; and Mr. George Taylor, of Mentmore, speaking of the successful working of Mr. Smith's system of steam cultivation on land in their occupation or under their management.

The CHAIRMAN regretted that the time had arrived for closing this discussion, more especially as he saw present several other inventors—amongst them Mr. Halkett—from whom he had hoped to hear some observations on this highly important subject. They would, however, all agree that Mr. Clarke was entitled to their best thanks for his able paper.

A vote of thanks was then passed to Mr. Clarke.

* See *Journal*, vol. iv. p. 175.

MR. HALL MAXWELL AND THE AGRICULTURAL STATISTICS OF SCOTLAND.

At Inverury, and within the Kintore Arms Inn there, the sixth day of February, Eighteen Hundred and Fifty-Eight; at a numerously attended meeting of Enumerators and members of committee connected with the Statistical Inquiry for the Counties of Aberdeen, Banff, and Moray:

On the motion of Mr. COPELAND, Haddo House, Mr. Geddes, Orbliston, enumerator for Morayshire, was called to the chair; and Mr. Murdoch Huntley was requested to act as clerk to the meeting.

The following resolutions were moved by Mr. HARVEY, of Tillygreig, seconded by Mr. JOPP SEGGAT, and unanimously agreed to, viz.:

"1. That the enumerators and members of committee present were induced to take charge of the Statistical Inquiry in their several districts and parishes, from a firm conviction that it would confer a great benefit not only on agriculturists, but on the community at large, and they had the more confidence in doing so from the fact that it was conducted under the auspices of the Highland and Agricultural Society of Scotland."

"2. That the meeting having had ample opportunities of admiring the great tact, zeal, and ability displayed in conducting the inquiry by Mr. Hall Maxwell, the secretary of the society, to whose indefatigable exertions the success which has hitherto attended it is mainly due, have observed with much regret that the requirements of Government from that gentleman have been such as to render the withdrawal of his services, and the consequent dissolution of the Highland and Agricultural Society's connection with the statistical inquiry necessary."

"3. That the meeting, referring to the growing interest taken in the agricultural reports, are satisfied that the measures adopted by Mr. Hall Maxwell for collecting the statistics—embracing as they do popularity, correctness, and economy—have obtained the greatest confidence among all classes connected with the inquiry, and produced a mass of such accurate and valuable information as could not otherwise have been readily procured."

"4. That the meeting having felt the utmost satisfaction in co-operating with Mr. Hall Maxwell in preparing the statistics during the last four years, though the employment as enumerators and members of committee was altogether unsolicited on their part, trust that matters may yet be arranged so as not to deprive the country of a system so thoroughly organized, and which, though apparently of an inquisitorial nature, has never been felt as such."

"5. That the Chairman be instructed to forward these resolutions to the Highland and Agricultural Society, and to send copies thereof to the Lords-lieutenant of Aberdeen, Banff, and Morayshires, to the Members of Parliament for these counties and burghs connected therewith, to the Right Honourable Lord Kinnaird, and to Sir James H. D. Elphinstone, of Logie Elphinstone, M.P." JAS. GEDDES, Chairman.

NORFOLK AGRICULTURAL SOCIETY.—In consequence of the decision arrived at by the late annual meeting with regard to the reserved fund, the premiums in all classes have been augmented to the extent of about £40. The classes of pigs are to be divided into the large and small breed. A new prize is to be offered for the best dairy cow of any breed, not being a Shorthorn, Devon, or polled cow. The money prizes for implements are to be given to collections instead of single implements. And medals will be awarded to newly-invented or recently-improved implements. The annual exhibition will, it is expected, be held at Norwich, Friday, June 18.

CHOOSING A SITE FOR A HOUSE.

In selecting a site for a country farm house, many things are to be taken into consideration. The question of healthfulness is of the first importance. Such situations as the border of a sluggish stream or of a stagnant marsh should be avoided. Soils retentive of moisture, and which draining cannot render dry and warm, should not be chosen. In such situations, desirable as they may be in other respects, the air is raw and chilly, the dampness rises through the walls and apartments of the house, discolours the paper hangings, spoils the food, diffuses a musty odour through every room, depresses the spirits, and injures the health of all the occupants.

Convenience and comfort should be considered. Fine prospects are fine things, but everything must not be sacrificed to obtain them. It would be folly in a farmer to perch his house on the highest peak on his estate, regardless of convenience of access to and from the highway, market, church, post-office, &c. Poets and "men of genius" may do such things, but ordinary mortals must have an eye to the common wants and comforts of life. Hence, we would set our house within easy reach from the road. It should not, indeed, stand close to the street, exposed to noise and dust, and to the prying curiosity of every passer-by. There is no need of crowding one's house upon the roadside. We beg pardon for saying it, it looks stingy to do so, and it looks as if the owner were excessively anxious to see and to be seen. Far better is it to lay off a liberal space in front and on the sides of the house, where trees and grass may grow undisturbed, and where the members of the household may enjoy themselves without undue exposure from the highway. Home is much less home if it have no privacy, if every opened door and window lets in the gaze of street-goers. We pity the members of that family who have no resources within themselves; who cannot find happiness in books, papers, company, music, trees and flowers, domestic labours and amusements, but must be for ever pining to learn the thousand little occurrences and gossip of the neighbourhood. Yet we would not go to the other extreme. Man is a social being, and it is very pleasant to see the faces and hear the voices of those who live about us. It is pleasant, especially for invalids, confined most of the time within doors, to be able to see from the windows of the house who are coming and going, and what is transpiring in the street. Then, in winter, it is very laborious to keep open paths to the highway from a house situated far from the road. We would, therefore, drive our stakes at a moderate distance from the street, leaving room enough in front of the house for lawn, trees and flowers, and yet so near the road as to be easy of access.

An elevated site is desirable, on many accounts. It affords facilities for drainage. The air is purer, drier and more bracing. The prospect afforded of the surrounding scenery is worth more than is generally paid for it: scenery is a gallery of pictures painted by the Great Artist. It is not all poetry to say that such a situation tends to inspire its occupants with an elevation of thought and feeling. Yet it must be borne in mind that such sites are exposed to violent winds, that in winter they are often blocked up by snow-drifts, that one must toil up and down the hills all his life, and that his loaded teams must daily be dragged up hill, or struggled with in going down. By no means should one take a calm, summer day to examine a hill-top for this purpose; let him rather choose a season of unpleasant weather, and if it bears examination then, it will be likely to prove satisfactory at other times. Most hill-tops are bleak, yet one is not sure of escaping severe winds by building in a low situation. Gales often sweep up and down valleys with great violence, with a sort of wildness and madness unknown on the hills. Blustering as is the winter weather of hilly regions, the actual cold, as measured by the thermometer, is seldom as great as that of the valleys, and late frosts seldom do as much damage in the one case as in the other. A sheltered situation is undoubtedly preferable to one open on all sides, and such a situation can hardly be found on a hill, yet much can be gained even on the most elevated spot, by planting belts of trees, chiefly evergreens, on the sides most exposed to the rake of the winds. In respect to elevation, our own choice would fix upon a gentle slope raised just above the damps and late frosts of the valley, and protected from the north winds by tree-clad hills.

It is often recommended to chose a site already clothed, more or less, with forest trees. There are advantages, certainly, in having such a basis for ornamental operations. It is a great saving of time and labour to buy your shade-trees already-grown. All you have to do in such cases, is to cut out roads and walks wherever they are wanted, to open up a prospect here, and plant a denser thicket there, and so to smooth out the tangled locks of nature as to develope her finest charms. This is all very well where it can be done; but such situations cannot always be found, combining, also, the other important features to which we have just alluded. And where they cannot be found, we would select one possessing the other desirable qualities, and then proceed at once to plant the ground with the best trees and in the best manner. With careful treatment, such trees will grow rapidly and develope a greater beauty than the tall, naked denizens of the forest ever present. Whether one lives to see his trees attain great size or not, is really of no consequence. There is more enjoyment in planting trees and watching their yearly improvement, than in sitting idly under trees already grown. A thousand associations spring up from year to year, and cluster around such trees. They are *your* trees:

you selected them, planted them, nursed them in their feebleness, defended them from their enemies, rejoiced in their prosperous growth, and now you gaze upon their spreading boughs and thickening shade with a sort of paternal pride and affection which you feel towards no other trees. Indeed, for our own part, we should shed few tears on being obliged to take a site without a tree upon it, —so far superior do we consider the pleasure of creating an attractive place of residence, to that of buying one already made. But tastes differ.

—COUNTRY GENTLEMAN. A. D. G.

ON UNIFORMITY IN NAME OF THE DIFFERENT ANIMALS OF THE FARM.

A considerable discussion is now going on throughout the country, relative to uniformity of weights and measures, The time, therefore, may not be inappropriate to introduce the subject as named above, embracing the multifarious and incongruous names as applied to the different farm animals, of the same age, kind, and character, in various parts of the country; a synopsis of which I give below. It is true that no great benefit is to be derived from adopting a uniform series of names to designate the same animals in different districts; but it seems to be very desirable for general information, and to give more simplicity to our farm designations. To foreigners, reading our works on agriculture, it must be very perplexing; and in our own country, our agricultural readers are often at a loss to understand the common and varied terms applied to the same animal in various localities, these terms by no means being descriptive of the animal, often the very contrary. Who would suppose the term "Hog" meant a sheep of one year old? Then, the terms "Chilver" and "Tiddlin," as applied to lambs; or Dinmont, Twinter, Gimmer, Theave, Hoggerill, Teg, Wether, as applied to older sheep; or again, the terms Kebbet, Guill, Eild, Guest, Shots, Crones, Crocks, as applied to the female sheep. What an inconsistent medley! many of these terms being unknown elsewhere than the locality where they are in common use. I might also instance many absurd names as applied to other animals, *i. e.*, Quey or Whye-calf, Wennel, Weanling, Stirk, Stot, Bud, Burling, Steer, Cuddock, &c., as applied to young cattle; or again, Drape, Dry, Gast, Gelt, Forra, Eild, Lease, Veer, Yule, as applied to cows; the meaning of which is almost unknown out of the respective districts where they are in use. Of horses and pigs I might give equally absurd names, but refer to my synopsis below. I have also thought it not inappropriate to couple with this subject the terms used in the driving and directing horses when in work. These are, if possible, still more unintelligible, not to say barbarous. The only remark I would make upon this point is, that it is highly important that one set of terms only should be in use upon the same farm, otherwise the horses are confused by a medley of sounds, and the wondering clodpole is astonished to find the horses do not comprehend him, and therefore frequently lashes them severely for his own fault. I am not about to suggest an alteration of this order of things by Act of Parliament, as in the agitation of the subject relating to weights and measures; but I would suggest a more uniform adoption of the best and most suitable terms by every intelligent agriculturist, by every agricultural writer, and by every agricultural journal or report. In this way, by continued perseverance, much may ultimately be done, and, as the intelligence of farmers is promoted, such relics of the olden time will fall into disuse. If I am asked who is to decide the precise terms to be adopted, I would reply that our great agricultural societies have mainly settled that question in their programmes and prize sheets. These terms I would adhere to with great pertinacity, so far as they are applicable: the many minor ones will, I think, eventually follow.

The following imperfect synopsis is taken from various sources:—

1st.—Names and designations relating to sheep, as used in different districts.

The male sheep is called a ram and a tup, almost universally.

The female sheep—a ewe (often pronounced yoe), almost universally.

The male lamb—a ram-lamb, a tup-lamb, weder-lamb, generally; and a pur-lamb, in the West of England.

The female lamb—a ewe-lamb, a sheder-lamb, very generally; a gimmer-lamb, in Scotland and the North of England; and a chilver, in the West of England.*

The male at one year—a lamb-hog, hog, a tup-hog, hogget, boggerill, wether-hog, teg.

The female at one year—a ewe-hog, a gimmer-hog, a ewe-teg, a sheder-hog.

Lambs brought up by hand—a cade-lamb, in Lincoln, &c.; and a tiddlin, in Wilts, Gloucester, &c.

The male at one and two years—a shearling, a shearing, a shear-hog, a shearling-wether, shearling-tup; a dinmont, in Scotland; and a twinter, in Stafford and North of England.

The female sheep at one and two years—a shearling-ewe, a two-toothed-ewe, a theave, a gimmer, a gimber.

Older sheep—a two-shear, a four-toothed, or a three-shear, a six-toothed-ewe or wether.

The female missing lambing—a barren-ewe, guile-ewe, eild-ewe, guest-ewe, tup-yeld-ewe.

The female having slipped her lamb—a kebbit ewe, cast-ewe.

Aged and rejected females—a cull-ewe, cast-ewe, shots, crones, crocks.

2nd.—Names and designations relating to cattle as used in different districts:

The male is called a bull, quite universally, *i.e.*, short-horned bull, Devon bull, Hereford bull, &c., &c.

The female—a cow, quite universally, short-horned cow, Devon cow, Hereford cow, &c., &c.

The male calf—a bull calf.

The female calf—a heifer calf, a quey calf, a whye calf.

The male castrated calf 1½ years—a yearling, a stirk, a weaned calf, a weanling, a burling, a bud, a stot.

The female calf 1½ years—a yearling heifer, weaned heifer, wennel heifer.

The male above 1½ to 3 years—a steer, a ha a hi (Scotland), two-year-olds, three-year-old steers, cuddocks.

The female above 1½ to 3 years—a heifer, a two-year, or a three-year-old heifer.

The barren female—a dry cow, eild cow, forra cow, drape cow, gast cow, gelt cow; or having missed calf, lease cow, veer cow, yule cow.

Cattle not having horns—a coost ox, dodded ox, hammelled cow or ox, mailed cow or ox, muil cow, mullock cow, not cow, powley cow or ox.

3rd.—Names and designations relating to horses as used in different districts:

The male is called a horse, a stallion, a coosar, a stoned horse, an entire horse.

The female—a mare, a nag mare, a cart mare, &c.

The young male—a colt foal, a yearling colt, a hog colt, a stag colt, a two-year-old colt, a three-year-old colt, a four-year-old horse, a gelding.

---

* I have not named a tithe of the districts where many of the same terms are in common use, nor have I enumerated all the names so used.

The young female—a filly-foal, a yearling-filly, a two-year-old filly, a three-year-old filly, a four-year-old mare.

4th.—Names and designations relating to pigs, as used in different districts:

The male is called a boar, a brawn, a hog-pig.
The female—a sow, a yilt.
The young male, castrated—a store pig, a gure, a shot, a yolk
The young female, spayed—a spayed sow, a clean cut sow, a sow pig.
The young female—a gilt, a young sow, a hilt, a gelt.
The birth of pigs—a litter of pigs, a fare or farrow of pigs, a farth of pigs, and pigging.
The smallest of the litter—a reckling, a krute, a rut.
The general terms are—bacon pigs, porkers, breeders, store pigs, grunters, piglings, &c.

5th.—Terms used in different districts in driving and directing horses in work, &c.:

To the right.	*To the left.*	*To go on.*	*To stop.*	*To hold back.*

THE LONDON, OR CENTRAL FARMERS' CLUB.

THE NECESSITY OF A UNIFORM SYSTEM IN THE SALE OF CORN.

The first monthly meeting of the members of the Club, for the present year, took place on Monday evening, February 1st, at the Club-House, New Bridge Street, Blackfriars.

Mr. Thomas Owen, of Clapton, Hungerford, Berks, presided as Chairman for the new year, supported by Messrs. H. Trethewy, J. Marshall, Owen Wallis, S. Skelton, B. P. Shearer, R. Baker, T. C. James, N. G. Barthropp, J. B. Spearing, C. Howard, W. Gray, J. Wood, J. Wood (Croydon), J. Cressingham, Robert Smith, E. Little, G. Smythies, W. Bullock Webster, H. Shotter, T. Congreve, M. Reynolds, J. L. Morton, L. Pearman, J. Tyler, John Thomas, G. S. Harrison, S. Sidney, J. Marsh, junr., H. H. Tatam, W. Eve, W. Cheffins, T. Hammond, J. G. King, C. Gorton, W. Brown, E. B. Acton, T. G. Dagg, &c., &c.

Mr. Owen Wallis, of Overstone-Grange, Northampton, undertook to introduce the subject for discussion:—"The necessity of a uniform system of weights or measure, in the sale of corn and other agricultural produce, throughout England and Wales."

The CHAIRMAN said, in occupying the chair for the first time, he begged to ask the indulgence of the Club, while he continued to preside over its proceedings; and he hoped he need scarcely say that he should use his best endeavours to promote the interests and prosperity of the Club (cheers). He trusted that the discussion of that evening would be carried on in that friendly spirit which had hitherto marked their proceedings. The subject on the card was one of great interest, not only to the Club, but to the community at large, and he hoped that they would be enabled to arrive at a decision which would guide the Legislature in a matter in which some alteration had long been required. He would now introduce Mr. Wallis, who would proceed to open the discussion, only adding, in conclusion, that he felt great diffidence in filling the chair which had been, during the last year, so ably occupied by that gentleman; but that he hoped, with the support of the members of the Club, to be enabled to perform in a satisfactory manner the duties which had devolved upon him (cheers).

Mr. WALLIS then rose and said: In appearing before you again at so early a period after quitting your chair, I feel that some explanation, if not apology, is necessary. On several occasions after our discussions last year, I called the attention of the Club to the anomalies existing in the weights and measures by which corn is sold in the different markets of the kingdom. My object in doing so, I need scarcely say, was to enlist the co-operation of this influential body; and by means of the publicity given to its proceedings in the agricultural press, to call the attention of the farmers, corn merchants, and millers to the evil, and by their united means ultimately to procure a remedy. A good deal of discussion ensued, and a committee was appointed to consider what steps should be taken by the Club in reference to the subject. At our meeting in June, it was thought very desirable to obtain the opinions of the public on so important a matter; and, with that view, a circular letter was placed at the head of the report of the discussion for that month, and in that way sent to the members of the Club. It was also forwarded in another form to all the boards of guardians, district farmers' clubs, and chambers of commerce in the kingdom, and replies to the questions contained therein requested. To this letter numerous answers have been received; and it was thought desirable that the substance of the opinions thus collected should be brought before the Club in a condensed form, and the whole subject again discussed, not incidentally, as during last year, but primarily, in order that a full report of the views and opinions of the Club may be circulated throughout the country. Having been instrumental in bringing the subject to your notice, I was requested to introduce it on this occasion; and though I felt assured that there were many members of your body more competent than myself for the task, I felt that I ought not to refuse, and thus impose upon another a duty I had myself declined. It was also thought desirable that the discussion should precede the regular meeting of Parliament, in order that the conclusions at which we may arrive should receive any consideration they may deserve, in case a measure for the establishment of a uniform standard of weights or measure for the sale of corn and other agricultural produce should be introduced in the House of Commons during the coming session. On that account it was placed first on the discussion card for the year, and it is for that reason I again appear so quickly before you. In accordance, therefore, with the expressed wishes of this Club, I have placed in a tabular form, which will be printed with this paper, the opinions of the different gentlemen who have been good enough to reply to our questions, and I pledge myself that they are, as far as I can gather them, a faithful transcript of those opinions (see pages 200 and 201).

Names of Clubs and Boards of Guardians.	For perfect uniformity.	To be made compulsory.	Will co-operate with Central Farmers' Club.	For Imperial Measure only.	For Weight only for all Corn.	For Measure with natural Weight stated.	Weights of Corn per Bushel.							Opinions expressed in the Returns to which they have reference.
							Wheat.	Barley.	Oats.	Rye.	Beans.	Peas.	Tares.	
							lb.	lb.	lb.	lb.	lb.	lb.	lb.	
Members of Central Farmers' Club.....	4	4	1	4	3	1	—	—	—	—	—	—	—	Eight members made returns, but I have not thought it right to state names.

These averages are very nearly, but not strictly correct.

* In taking the averages of weight at which wheat has been returned, I have not included this return. It has doubtless been given as a customary weight, and not as fairly representing the average weight of an Imperial bushel.

The returns are from eight members of this Club, twenty local farmers' clubs and agricultural societies, and sixty-four boards of guardians; and on reference to column No. 1, it will be seen that there is an entire unanimity as to the desirability of abolishing the great diversity of weights and measures at present existing, and of establishing a uniform standard. This, though very gratifying, is only what might have been expected. Indeed, the present system is altogether indefensible; and it seems perfectly marvellous that it has been tolerated so long. Time has been, when this mystification of the many was doubtless to the benefit of the few. That, however, has already passed, or is rapidly passing away; and as all concerned are inconvenienced, and very few profit by it, the desire for an entire change is rapidly gaining ground. It seems almost needless to dwell on this part of the subject, further than to place on the records of the Club a list of weights and measures by which corn is sold; and if it is instrumental in bringing about their destruction, and in establishing one only as a standard, it will not have existed in vain. The measures for wheat are as follows: The last of 10 qrs.; the load of 5 qrs., 5 bush., and 3 bush.; the quarter of 8 bushels; the coomb of 4 bushels; the bag of 3 bushels; the boll of 4 bushels and 2 bushels. The weights for wheat are as follows: The bushel of 80lb., 75lb., 72lb., 70lb., 67½lb., 65lb., 64lb., 63lb., 62lb., 61lb., and 60lb.; the load of 488lb., 280lb., and 261lb.; the boll of 240lb.; the bag of 12 score, 11 score and 10lb., 11 score and 4lb., and 11 score; the barrel of 238lb.; the windle of 220lb.; the hobbit of 168lb.; also by weight of 40 stone, 36 stone, 20 stone, and 14 stone; also by 480lb., 224lb., 190lb., 140lb., and 112lb. The measures for barley are—the quarter of 8 bushels; the coomb of 4 bushels: the bag of 3 bushels; and the bushel of 39 quarts and 38 quarts. The weights for barley are—416lb., 112lb.; the boll of 320lb.; the barrel of 224lb.; the hobbit of 147lb.; 32 stone, 30 stone, and 12 stone; the bushel of 60lb, 56lb., 54lb., 52½lb., 50lb., 40lb., and 38lb. Oats are sold by the qr. of 8 bushels; the bag of 3 bushels; the load of 196 quarts and 192 quarts: also by the following weights—The boll of 264lb.; the load of 240lb.; the barrel of 196lb.; the hobbit of 105lb.; the bag of 8 score; the cwt.; the stone; and the bushel of 45lb. and 40lb.; and by 24 stone. Beans by the qr. of 8 bushels; the load of 5 bushels, and of 144 quarts; and the bag of 3 bushels: also by the following weights—320lb., 280lb., 220lb., and 112lb.; by 10 score; by 38 stone; the windle of 220lb.; and the bushel of 66lb. and 63lb. Peas by the qr. of 8 bushels; the bag of 3 bushels; the bushel of 63lb.; and the boll of 280lb. Rye by the qr. of 8 bushels, and the bag of 3 bushels; and by weight of 320lb. Tares by the qr., the bag, and the bushel. Flour is also sold by the sack of 280lb.; the pack of 240lb.; the barrel of 196lb.; and the stone of 14lb. Indian meal by the load of 240lb, and the barrel of 196lb. Oatmeal by weight of 240lb. and 112lb. Indian corn by the qr. of 8 bushels; and by weight of 480lb. and 180lb. Malt by the qr. of 8 bushels, and the load of 6 bush. Such are the weights and measures by which corn, meal, and malt are now sold in the different markets of the United Kingdom, as far as I have been able to ascertain them; but there are, doubtless, many others. Those enumerated amount to a goodly number, being, for wheat alone, no less than 41; for barley, 20; oats, 14; beans, 13; peas, 4; rye, 3; tares, 3; Indian corn, 3; malt, 2; flour, 4; oatmeal, 2; and Indian meal, 2. They are, as a whole, a disgrace to the country in which they exist; and I hope shortly to hear the last of them, except as historical curiosities. I am not acquainted with the weights and measures of other civilized countries, but should fancy that ours can have no parallel. We have so far considered the question as effecting corn, meal, and malt only; but there are a host of weights and measures for meat, butter, cheese, potatoes, fruit, hay, straw, &c., alike perplexing and inconvenient, and therefore objectionable. Having pointed out the evils, we must now consider what is likely to be the best remedy; and I hope the members of this Club will be ready and willing to set an example to their brother-farmers and merchants throughout the kingdom, by showing an earnest disposition to submit to a temporary inconvenience in order to attain a great public good. There can be no such changes as that we are now contemplating, without a considerable amount of personal inconvenience; but prices would immediately adjust themselves to any given standard, and in a very short time we should find the new one quite as convenient as the old: and, by being of general, instead of only local use, it would be infinitely more satisfactory. The greatest obstacles to be contended with will be local prejudices. Each district thinks its own custom the right one, and makes a desperate stand for its retention. There are, as I have shown to you, more than forty different weights and measures in use for the sale of wheat alone; and if there are to be as many battles in the endeavours of each locality to secure the future use of the one it has been accustomed to, how small will be the chances of a beneficial result! Rely upon it, the change at which we are aiming can never be accomplished until those interested in its attainment are unanimous in their desire for it, and ready to make sacrifices in order to obtain it. They must also make that desire known to the Government in terms most unmistakable, for I believe no really beneficial change will ever be made till the Government takes the matter in hand. And now let us consider what that change should be. The first point to be decided is this: Are we to have a measure of capacity? or, are we to have one or more of weight? or are we to have a combination of the two? If a measure of capacity, the imperial bushel will answer every purpose; but if we adopt weight, we shall then have to consider what it shall be, or how far it will be right to use weight and measure together. In our endeavours to select a new standard of measure by which the sale of corn and other agricultural produce shall in future be conducted, we must be especially careful to select one on which perfect reliance can be placed for its unerring accuracy. Unless we do so, no Act of Parliament will ensure its adoption, and no amount of fines make its use compulsory. Now, does the bushel measure fulfil that necessary condition? I say most emphatically that it does not; and hence its use, except in name, is rapidly declining. It is by no means an accurate test of quantity. It was, in times past, the best available measure; but that is no longer the case. Its invention was probably coeval with the flail and the winnowing-fan; and it would be just as wise to revert to those implements for the purpose of thrashing and dressing all the corn we grow, as it will be to continue the bushel measure for the purpose of ascertaining the quantity of it. With the best possible intentions of doing right, the man has never existed who could measure up a quantity of corn with it, however uniform the bulk might be, without their being variations in the weight per sack, when tested by an accurate weighing machine; and it is very easy so to measure it that very large differences will be the result, and yet a person overlooking the operation could make no objection to the measure. In trying the experiment the other day with oats, we made as much as 3½ lbs. per bushel difference, and in no instance

could we get two bushels exactly alike in weight. I have been told by a corn-merchant that it is not at all uncommon to have corn delivered varying as much as 7 lbs. the sack of 4 bushels; and hence, I repeat, its almost general disuse. I would not dwell on this point, but from the circumstance that the imperial bushel has still many advocates. Judging, however, from the answers to the circular-letter issued by this Club, they are greatly in the minority, as will be seen by reference to the table of returns which I have drawn up. From this it appears that of the members of this Club four are for measure alone, three for weight alone, and one for measure and weight combined. Of the local farmers' clubs, three are for measure, ten for weight, and four for measure and weight. Of the boards of guardians, twelve are for measure only, thirty-six for weight only, and ten for measure with weight declared. The totals will therefore be—for measure alone, nineteen; weight alone, forty-nine; and measure, with weight stated, fifteen. This last is, in fact, selling by weight; for if the corn which is bought on these terms is delivered in accordance with the weight stated, and of the quality of the sample, no questions are asked as to the correctness of the measure. I contend, therefore, that the advocates of weight alone, and those for measure with weight stated, ought to be added together. The totals will then be 19 for measure, against 64 for weight. If we take this as a fair expression of public opinion—and I think we cannot do otherwise, collected as it is from all parts of the kingdom—the question of measure as against weight may be considered as settled in favour of the latter. We will next consider the propriety of selling corn by measure, but stating its natural weight. That this plan is very convenient to many gentlemen engaged in the corn trade, I have no doubt; indicating, as it does in some degree, the quality of the corn they are buying. But on this point I cannot do better than quote the opinions of the members of the Wirral Agricultural Improvement Society, as expressed in their very valuable report on this subject. They say, "That weight simply, without such an indication of the specific weight as is afforded by a statement of the weight per measure, affords no indication of quality, your committee unhesitatingly admit. But on the other hand, they must affirm that the proper purpose of weight or measure is not, and never has been, to indicate quality; that the mere specific gravity of corn cannot, in an average of cases, be taken to prove its value, in point of quality, within ten per cent; and that, in practice, neither corn nor other agricultural produce is ever bought without being seen and handled, either by the buyer or his agent." In this opinion I entirely concur; and further, I contend that the sellers of corn ought not to be called upon to incur the double expense of measuring and weighing. But there is a still greater objection to this plan. Quotations of prices can never fulfil their proper intention, and be of any real value, till they refer to fixed and definite quantities, and these we can never have with an ever-varying standard. We see a price quoted as to wheat in a distant market, but we do not know whether it has reference to sample weighing 54 lbs. or 66 lbs. per bushel, or any intermediate weight. The quotation is therefore valueless, and that consideration alone is, I think, an insuperable objection to such a standard. This objection applies also, with equal force, to measure without weight. We come last to a standard of weight, and we shall have to consider whether it will be best to have a variety of weights, one suitable to each variety of corn, and fairly representing an imperial bushel of each; or, whether we shall adopt one weight for the sale of all corn and other agricultural produce. If we are perfectly free to choose between the two—and I think it will be found that we are—I am strongly of opinion that it will be much better to adopt one standard than several. As between the buyer and the seller, it must be a matter of perfect indifference what the quantity is, so that it is fully understood; and the more I have thought of the subject, the stronger has become my conviction, that it will be an immense convenience, and greatly to our advantage, to sell all corn and other agricultural produce by one weight only. If corn and meal of all kinds, bran, pollard, oilcake, linseed, locust beans, hay, straw, roots, &c., were each sold by one weight, any one wanting to buy for feeding purposes would see at a glance which was best worth purchasing, without the necessity of troublesome calculations. The adoption of one weight only, is strongly advocated by the Wirral Agricultural Society, the Association of the Liverpool Corn Trade, the Corn Exchange Association of Hull, the Markets Committee of the Town Council of Edinburgh; and I have also received several letters from gentlemen residing in different parts of England, advocating such a standard. Some suggest 100 lbs. as a desirable weight, having in view future decimal weights and measures: others think the cwt. better, having no faith in the establishment of either decimal weights or coinage in our day; and to this opinion I also incline. Having all the necessary weights in use for carrying out a standard of 56 lbs. or 112 lbs., I should prefer one of these, if practicable. It will, I know, be urged that for the purposes of the tithe commutation and the corn rents, it will be absolutely necessary either to adhere to the imperial bushel, or fix upon a standard of weights that will fairly represent it, with respect to each variety of corn. I cannot imagine any great difficulty in this latter point, if fairly and honestly set about. There are numbers of millers who have the weight of every load of wheat they have purchased; and there are corn merchants and others, who can give similar evidence. The weight per bushel being settled—making that the datum for other calculations—I can scarcely think there can be any insurmountable difficulty in preparing a new set of tithe tables, showing what rent-charge shall be paid according to the average price of corn, upon a fixed standard of 56 lbs. or 112 lbs., or whatever it may be. I may possibly be wrong, and we may have to fall back upon weights representing a bushel of each corn. Should this be the case, I think it will be a matter to be regretted; but even that will be an immense improvement upon the present state of things, which I trust will no longer be tolerated. In conclusion, let me urge upon you, and all others, the necessity of thoroughly agitating the question in every part of England, and let each market in England send petitions to Parliament on the subject, or rest assured there will be no beneficial change. Let one and all leave *self* out of the question, not minding a little perplexity in having to sell corn by the cwt., or some other such standard of weight. It has been the custom of Ireland for ages; and what is perfectly convenient there, can be attended with no very great difficulties in England, Scotland, and Wales. With respect to the sale of barley by weight, I will read the following remarks from a correspondent of the *Economist* newspaper: "I perceive with satisfaction that others as well as myself are directing their attention to the fact that corn, like many other commodities, should be sold throughout the United Kingdom by weight alone, and not according to the present system of selling by dry measure. The superiority of the scale, in point of accuracy and impartiality between buyer and seller, cannot be questioned; and the inconsistency of our buying coals, &c., by pounds avoirdupois, and corn by cubic inches, must be equally apparent. Allow

me, sir, as one who feels some interest in this question, and who earnestly wishes to see the bushel measure superseded by the scale and balance wherever practicable, to suggest that it would be most desirable for maltsters to buy not only their grain by weight, but that the Excise officers, in computing the duty, should be guided by weight alone—or in other words, that the maltster should be charged according to the weight of raw grain which he intended to use, and not upon the gauge of the malt in the process of making. It is needless to dilate on the justness of such an assessment as I here propose, or to dwell upon the advantages which must result from so fair and simple a practice. The maltster would be spared much vexatious and unnecessary injury to his grain; the Excise officer would be relieved of half his labour and full three-quarters of his vigilance; and her Majesty's revenue be greatly benefited—first, by reason of the extreme simplicity of such a system; secondly, by the ease with which fraud could be prevented and Excise regulations enforced; and thirdly, by the extra amount of duty that would accrue to the Government on a large quantity of lighter barley which would under such an arrangement be certainly made into malt, but which under existing statutes could not be so employed, because it would entail only loss upon the manufacturer. I do not advocate the instant abrogation of the law as it now stands with respect to malting, and far less do I desire to abolish the heavy list of penalties, from which the fair trader has nothing to fear, for it is a protection rather than otherwise; but I think if her Majesty's Board of Inland Revenue could be induced to consider the subject, we might in a short time see maltsters paying their duty by the weight of barley to be wetted, and not by the uncertain and clumsy method of the gauge, and still more uncertain calculations of the exciseman, from whose decision there is little or no appeal." If this view of the question is a correct one, its adoption would be a great boon to the growers of second-rate barley, by causing a demand for it, for malting purposes, which does not at present exist. It has been suggested by the Louth Agricultural Society, and also by others, that this Club should agree upon a petition to the Legislature, and forward copies of it to other agricultural clubs for their adoption and use. I think this a desirable plan. I will not trespass longer upon your patience, further than to again urge the absolute necessity of a general and decided expression of public opinion in favour of the change we are advocating, as the only probable means of its accomplishment. Let me just add, that since I came here this evening I have received a letter from Mr. Bailey Denton, requesting me to call the attention of the Club to the irregularities of measures which prevail with regard to land. I have also received a communication of a similar nature from another gentleman. A land-agent residing in the neighbourhood of Liverpool says that within five miles of his own residence, no less than three kinds of acre measurement, are in common use. First there is the statute acre, of 5½ yards to the rod; next there is the Cheshire acre, of 7 yards; lastly there is the Derby acre, of 8 yards. Of course, such a state of things is very perplexing, and urgently requires attention. Having made these remarks, I sit down, thanking you all for the patience with which you have listened to me (cheers).

Mr. R. BAKER (of Writtle) said it could not be disputed that if one uniform system of weight or measure prevailed it would be much preferable to the variety which now existed throughout the kingdom. The question then was, whether weight or measure was the better of the two. Mr. Wallis had argued that if weight were established it would be a criterion of the value of grain that might be estimated by persons at a distance merely reading the report. He (Mr. Baker) differed from that opinion, for this reason, that weight had nothing to do with value; that quality entered more into the computation than either weight or measure, and that whenever a bargain was made the two must always operate upon the mind of the buyer. In Chelmsford market a bushel of wheat was generally estimated to weigh 62 lbs., whether it was red or white wheat, but the value was essentially dependent upon the quality; and there were many instances where wheat, grown in particular districts of the country, invariably made as much as 6s. per qr., or nearly a shilling a bushel, more than wheat which was grown in other districts. Besides, measure had always been the established mode by which corn had been sold in this kingdom for ages past. The Winchester bushel was for a long time the bushel of the country. That was increased to the imperial bushel, amounting to one thirty-second part more, and that bushel was now the standard measure of the kingdom at large. Upon that measure the tithe commutation, corn rents, and duties of import were based; and wherever any other measure existed, whether of weight or capacity, or of weight and capacity combined, it was in contravention of the law of the land. The act of parliament directed that the imperial bushel should be the universal measure; but very unwisely a provision was tacked to one of the clauses, which permitted the continued use of local measures in districts where they had long existed, and exempted them from penalties. This left a loop-hole for employing the measures and weights of various districts, in the same manner as if the act had never been passed; but it was not to be supposed, therefore, that the Legislature would retrace its steps and enact that certain weights, or measures and weights combined, should supersede the measure established by law. With regard to the difficulty of delivering by measure, all he (Mr. Baker) could say was that he himself delivered by measure all the year round, and had never had any complaint from the miller; indeed, there was no reason why there should be, where people were accustomed to put up corn. If a person measured a bushel of oats, as Mr. Wallis had stated, upon a shaky floor in a granary or mill, or did not take due precautions, then it was not improbable that it might make a difference of 3 lb. in the bushel. But it could not alter the quality whether it was sold by measure or weight. He held, then, that every farmer who went into the market could previously ascertain the weight per bushel of the corn he had to sell. It might be thought that that was an advantage which the seller had over the buyer; it was not so, however. Buyers could compute corn to the greatest nicety, as the following anecdote would sufficiently show: A certain miller made a wager that he would compute the weight of a sack of wheat nearer than ten farmers could weigh it, and he won the bet. The fact was, that each farmer weighed it in his own particular way, some with bad scales and others with steelyards, and the results could not be depended upon. The miller's judgment was so good that he computed the weight within 2 lbs., and that was nearer than the farmers could arrive at with their scales and weights. This showed that notwithstanding all the skill that the farmer might possess, the dealer on account of his great practice had an advantage over him in this respect. As representing in that Club the eastern district of this kingdom, where measure of capacity was universally adopted, he felt bound to state that the opinion of the farmers in that district was, that measure was the established principle on which corn should be bought and sold, and that their desire was to continue its use. If the system of weight were adopted, he had no doubt that the farmers of the eastern district would as easily fall in with it, as a farmer of the west could adapt himself to measure; but it should be recollected that they who did not possess weights would have

to incur considerable expense in order to procure them; whilst, on the other hand, the purchase of a measure would be a very trifling affair in comparison. The existing law having been enacted so recently, he did not think that any resolution which this Club might come to would induce the Legislature to alter it. In fact, he had arrived at the conviction, after maturely considering the question, that there was no necessity for an alteration, or any reason why the imperial bushel should not be the standard by which all weights and measures of corn should be adjusted (Hear, hear).

Mr. SKELTON (of Sutton Bridge, Wisbeach) said, having had considerable experience with regard to this subject, both as a farmer and as a corn-merchant—an experience extending over more than 30 years—he was desirous of making a few remarks. The necessity of having a uniform system was no longer disputed; they all felt that the crude and manifold modes of selling corn, which had hitherto prevailed in various parts of the kingdom, required immediate alteration. As regarded the practicability of attaining uniformity, he really saw no insuperable difficulties, though he must admit that penalties were not agreeable either to farmers or to the public at large (Hear, hear). What was spoken of on the card was "a uniform system for England and Wales." He could not understand why Scotland was omitted; in his opinion there ought to be uniformity throughout the kingdom (Hear, hear). Moreover, he thought the principle of uniformity should be applied not only to all the corn grown in the United Kingdom, but also to all the corn imported from abroad, so that the comparative value of the two might be ascertained through the same medium. Mr. Wallis had alluded to the local prejudices which were opposed to any change of the existing state of things. Having a very extensive circle of acquaintance connected with the corn-trade, he had been in correspondence with several gentlemen on the question under consideration, and the result was that persons who had been in the trade many years had pronounced the object almost impracticable. They referred to France, in support of their view, and remarked that in that country the government, notwithstanding all its arbitrary power, had hitherto failed to establish a uniform system. In the opinion of those gentlemen as to the impracticability of the object he did not concur, believing as he did that if the matter were duly discussed, were talked over at market ordinaries, and well considered in private, they would be enabled to arrive at a practical result. He could not help here remarking on the importance of having an amended system of taking the corn averages (Hear, hear). A friend of his, Mr. S. Sandars, who had had a very long and extensive experience in the corn trade, and well up to all the bearings of this subject, had suggested that no buyer should be required to make a return of any corn except that which he had purchased from the grower; the reason given by him for this suggestion being that the same corn had frequently been sold two or three times over, on a market day, the charges upon it being thus considerably increased. Under the existing law, the buyer was compelled to make a return of all the corn bought by him, without reference to the place where it came from, or the expenses which might have been added to it; and this was an important matter for those who had to pay the tithe rent-charge, or corn rents. He trusted that whenever a uniform system of selling corn was established, the subject of the mode of taking the averages would not be overlooked. As regarded the question more immediately before them, it should be borne in mind that the tithe rent-charge was based on returns made by measure, that the corn-rents were based on measure, and that import duties and freights were also founded on the same principle. With respect to weights, he thought it would be very difficult to arrive at a sound conclusion as to what should be the fixed weight for all seasons, for all soils, and for all districts (Hear, hear). They all knew very well that the seasons made a great difference (Hear, hear). In the year 1852, his shipments were generally made at from 57lbs. to 58lbs. per bushel; while in the year 1844, they were made at from 63 lbs. to 64 lbs. Such was the effect of the difference of seasons. Then, again, they all knew that different soils gave different weights; and hence he concurred in the remark of Mr. Baker, that weight did not always represent quality. It was well known that some soils yielded a thin-skinned wheat, which though superior in quality to the coarser wheat of other soils, was not equal to it in weight. He fully agreed with Mr. Baker in reference to the amount of ability and skill displayed by many persons who were engaged in the corn trade as millers and merchants; but he maintained that as it was an object with the seller and buyer to carry on their business to mutual advantage, in order that they might come together a second time, it was necessary when wheat was not in good condition that the seller should name a given weight; otherwise how could the buyer form a correct judgment? It was impossible that he could do so from a sample shown in the market, when the corn was out of condition; and it was but fair, therefore, that in such cases the seller should name a weight. Mr. Wallis had spoken of the double expense of weights and measure. In Norfolk, also around Wisbech, &c., it was the common practice, after the corn was dressed, to order the men to measure four bushels; and the weight of these having been ascertained, no further measuring was required; the farmer went to market, stating that he had so much corn to sell of that given weight. Now, he had received various suggestions with reference to this subject; some to the effect, that corn should be sold by the cwt., others in favour of the imperial measure, and others of a different nature. He should be very glad to see a uniform system, more intelligible and convenient than the present state of things; but the great question was to what it should be. The words on the card were "a uniform system of weight or measure." He should greatly object to the re-opening of the question of the tithe rent-charge, which had been settled to the satisfaction of all parties; and if it were re-opened, there could be no doubt that the clergy would, and he must say very properly, come forward to defend their rights; while many landlords would also become alarmed. His own opinion was that the imperial measure should be retained; but its use should be enforced universally, not only throughout England and Wales, but also in Scotland and Ireland, and that all foreign corn should be included in the operation of the law.

Mr. TATAM observed that foreign corn already paid duty by measure.

Mr. SKELTON continued: His own observation and experience were in favour of adherence to measure; and he would recommend that Parliament should be petitioned to enforce uniformity by the Imperial quarter of 8 bushels.

Mr. G. SMYTHIES (Marlow, Leintwardine) said he entirely concurred in the able address of Mr. Wallis; he did not recollect a single word in it from which he dissented. In his own county he was in the habit of attending three markets, and at those three markets he was obliged to sell by different weights. It was all weight, not measure; and from his experience on the subject he was quite sure that in those districts where weight was already established, no legislative enactment for carrying out the principle of measure could be enforced. Weight was so much preferred to measure by those who had tried it, that he felt certain that the imposition of penalties could

never induce those who had habitually used the former to adopt the latter in its stead. He did not believe were a dozen farmers in his district who had there departed from the old system of selling by weight since the last enactment first came into operation; so superior had selling by weight been found in practice to selling by measure. There seemed to be a general desire, not only in that room, but throughout the country, that some uniform standard should be adopted. The question to be determined was what the standard should be; and, as selling by measure had been tried and found wanting, he thought all parties must soon follow the plan of selling by weight. He doubted whether the country was yet ripe for the adoption of either weight or measure as a universal system, but he was confident that the discussion of the subject would ere long lead to a satisfactory decision. Sale by 56 lbs. or 100 lbs. would be a very convenient mode of selling. Either of those weights would form a very suitable load for one man, whereas it was impossible to assert anything of that kind with respect to 4 cwt.

Mr. H. Trethewy (Silsoe, Ampthill) said it appeared that whether they adopted a resolution in favour of weight or one in favour of measure, they would equally offend the prejudices of many districts of the country (Hear, hear). They were told by Mr. Baker that in Essex measure had been adopted and acted upon for many years, and had proved perfectly satisfactory; while, on the other hand, the last speaker said, in effect, that in his part of the country parties would not listen to a proposal to sell by measure. It was quite obvious, therefore, that whatever course might be recommended by that Club, the recommendation would meet with great opposition in certain districts. It was of course very desirable that some specific course should be followed; but he must confess that the question appeared to him an exceedingly difficult one. If they had to start afresh, weight would no doubt be generally preferred to measure, as being the most easy and practicable system; but, on the other hand, when all commercial regulations were, so far as corn was concerned, based on measure, it was extremely questionable whether weight could be universally substituted for it. When this subject was first mooted in the Club, the tithe rent-charge seemed to him to present a great obstacle to any alteration; and the more he had thought on the matter since, the more had he felt the force of that objection. The tithe-rent being based on a bushel of wheat, if the bushel were required to co ıtain so many pounds, in districts where the wheat was light the farmer would have to pay an increased tithe-rent; and, in like manner, the producer who paid a corn-rent might, under certain circumstances, be made to pay a higher rent than the landlord was fairly entitled to receive. These appeared to him very great obstacles to any alteration which was to be carried out everywhere; and he entertained very strong doubts whether the Legislature could be prevailed upon, through any resolution which they might adopt that evening, or on any future occasion, to retrace its steps (Hear, hear). The imperial measure now appeared so natural—all the calculations connected with corn were so much based upon it—that in his opinion it would be impossible to upset it. He cordially concurred in many of the remarks made by Mr. Wallis; but he saw much greater obstacles to the establishment of a uniform system than appeared to have presented themselves to the mind of that gentleman (Hear, hear).

Mr. H. Tatam (Moultan, Spalding) must remind the meeting that the imperial bushel consisted legally of so many square inches of water, which was to be of a certain heat; so that when they went back to the primary state of affairs, they found that a bushel of wheat was constituted by weight. He did not believe there would be any difficulty in arriving at a fair average weight for the whole kingdom, or in prevailing upon the Legislature to establish a uniform system.

Mr. S. Sidney (of Peckham) said there could not be the slightest doubt that the question under discussion involved difficulties, but he saw no reason why they should not attempt to grapple with them. A few years ago every county had a metropolis of its own, and the farmers living in it never dreamt of sending their corn to the London market; but a great change had since occurred, and it was absurd to think of adhering to a system, simply because it had prevailed among their ancestors. Here was corn sold in half-a-dozen different ways in different districts, so that between weight and measure it seemed almost impossible to understand the operations of the corn trade. Under these circumstances the question was, how they could best attain uniformity. They certainly could not attain it by each dwelling on the particular plans followed in their respective counties, and contending that theirs was the only plan that could be carried out universally (Hear, hear). It was an important fact, that wherever a tendency had been exhibited towards change, it had been in the direction of weight (Hear, hear). That was a fact which the advocates of measure could not deny, and the inference from which was obvious. They had before them, as it were, that evening, the measure system on the one side, and the weight system on the other; and he hoped they were not going to separate without having taken a step towards telling the Legislature which of these systems they thought best for the whole country (Hear, hear). They might depend upon it that if they did not contribute to the settlement of the question, it would be settled without them. No one could imagine that the present absurd state of things would continue very long. If a resolution were adopted in favour of some uniform system of weights, the wide extension of the educational movement would secure the requisite knowledge for carrying it out in the schools scattered throughout the country.

Mr. Thomas (Bletsoe, Bedfordshire) said he regarded the question under consideration as a question of weight or measure. He entirely concurred in the remark that from 2lbs. to 3lbs. more or less might be put in a bushel by one person than by another, according to the mode in which the thing was done; and, when that was the case, why, he asked, should the imperial bushel be adhered to? For a considerable time he was not able to deal with a particular miller, because the miller said his bushel was not large enough (great laughter). Under these circumstances he offered to send his bushel to the county town, to be tried by the regular tester, with the condition that he should forfeit £5 if it were not true, and the further condition that the miller should send his bushel also to be tested, and forfeit £5 in case that were found defective. In point of fact, he sent his own bushel, and it proved to be perfectly correct. The miller then refused to imitate him in that respect, and the dispute was terminated over a bottle of wine. It was then agreed between them that his (Mr. Thomas's) bushel should in future represent a certain weight; and after that principle had been adopted, he sold to his friend a large quantity of corn, and they went on very amicably. He mentioned this merely to illustrate the difficulty there was in always making the same weight with the imperial bushel

(Hear, hear). He found that there were variations in the sacks, which sometimes amounted to as much as two or three pounds. He maintained, therefore, that the imperial bushel was not a fair standard, and that there should be some weight to represent the imperial bushel, as nearly as possible, throughout England and Wales, and also throughout Ireland and Scotland. It was admitted, he thought, on all hands, that there was no fairer test than dead weight. Why, then, should not the imperial bushel be represented by a certain dead weight? Whether the standard weight should be sixty, sixty-one, sixty-two pounds, or more, was of course a matter for consideration; but he thought that, on an average of years, sixty pounds would be found the nearest to the mark. Since the subject was discussed last year he had taken the trouble to make inquiries of his neighbours, and of other persons in various localities, as to their opinions in reference to this matter, and he found that a decided majority of them were in favour of having some uniform weight, representing as nearly as possible the imperial bushel. He quite agreed with Mr. Wallis, that this difficulty of ascertaining the value of wheat, from the quotations of customary local weights or measures, was ordinarily far greater in the case of the farmer than in that of the corn-merchant and the miller. The latter always had their Ready-reckoners with them, and could soon arrive at a correct estimate of value—a matter often of considerable difficulty to the producer. For these reasons, he was of opinion that the establishment of a uniform weight would be the best settlement of this vexed question.

Mr. DAGG (Hatfield, Herts) observed that, with the exception of the last speaker, no person who had taken part in the discussion had stated whether he had himself bought or sold by weight or by measure. When he first went to Mark Lane to buy corn, he asked the weight per bushel, but could never get any one to tell it; and this was an impediment to transactions. For the last seven years he had never bought in any way except by measure, with a guaranteed weight; and he was of opinion that measure should be retained, it being left to the buyer and seller to make their own bargain with respect to weight (Hear, hear). In fifty quarters of oats he had deducted as much as six shillings and sixpence for sixty-six pounds of deficient weight. The Norfolk plan seemed very fair dealing, and on the whole, he thought the use of the imperial bushel, accompanied with a guaranteed weight as between buyer and seller, was the best system that could be adopted; and he believed that, practically, such a system would not interfere with the tithe rent-charge, the duty on importations, or any existing arrangement.

Mr. LITTLE (Landhill, Chippenham) said, having adopted the plan just described by Mr. Dagg, he begged to say he had found it very advantageous to him as a farmer. In his own county—Wiltshire—it was very much the practice for farmers to combine a guaranteed weight with the imperial bushel, and it was a practice which had generally proved very satisfactory to all concerned. He really believed that it was the best system that could be established as a uniform system, and the best compromise that could be effected.

The Rev. C. T. JAMES said it was important to remember that the tenor of the act of Parliament was decidedly against weight, and in favour of measure. It was only by an *addendum*, as it were, to the act—an *addendum* which seemed to have been introduced inadvertently—that farmers were enabled to sell by weight. He should be heartily glad, if it were practicable, that all corn was sold by weight, because in the arrangement of our animals, we should then more largely feed by weight; but he could not overlook the manifest intention of the Legislature. The 5th and 6th Will. IV. abolished the use of all local and customary measures. This was done in the 6th clause, as follows: "And be it enacted, That from and after the passing of this Act the Measure called the *Winchester* Bushel, and the Lineal Measure called the *Scotch* Ell, and *all local or customary Measures, shall be abolished;* and every person who shall sell, by any Denomination of Measure other than One of the Imperial Measures, or some Multiple or some aliquot Part, such as Half, the Quarter, the Eighth, the Sixteenth, or the Thirty-second Parts thereof, shall, on Conviction, be liable to a Penalty not exceeding the Sum of Forty Shillings for every such Sale." Those words he could easily understand. But then came a proviso in the same clause, which was inconsistent with what preceded it: "Provided always, that nothing herein contained shall prevent the Sale of any Articles in any Vessel, where such Vessel is not represented as containing any Amount of Imperial Measure, or of any fixed, local, or customary Measure heretofore in use." Thus the second part of the clause nullified the first, and gave a sanction to selling by weight, which was not contemplated, probably, when the act was passed. The 8th clause, which was also a very important one, was as follows: "And whereas some Articles heretofore sold by Heaped Measure are from their Size and Shape incapable of being stricken"—the use of the word "stricken" was very significant, as showing that Parliament intended all sales to be made by measure—"and from their Nature and Quality may not be conveniently sold by Weight: Be it therefore enacted, That all such Articles may henceforth be sold by a Bushel Measure," &c. Again, in the 16th clause, Parliament said: "And be it enacted, That in *Scotland*, from and after the passing of this Act, the Fiar Prices of all Grain in every County shall be struck by the Imperial Quarter, and all other Returns of the Prices of Grain shall be set forth by the same, without any Reference to any other Measure whatsoever; and that any Sheriff Clerk, Clerk of a Market, or other Person who shall offend against this Provision shall forfeit a Sum not exceeding Five Pounds." Notwithstanding this enactment, the greatest diversity still prevailed in Scotland. He (Mr. James) had himself resided and occupied land within reach of four market-towns, in every one of which a distinct system of purchase and sale prevailed. Such diversity was very inconvenient and injurious to the seller, was very perplexing to the merchant, was fraught with evil consequences to the miller and the baker, and was in numerous instances very unjust and distressing to the hard-working and meritorious poor (Hear, hear). He held in his hand a letter from a miller, which appeared to him deserving of attention. The writer said: "There is a general complaint that farmers do not deliver as sample. Wheat weighs from 65 to 52lb. per bushel; and, in consequence of its being *made* a certain weight, it is impossible to discriminate. The buyer is deprived of the *best guide*, the *natural weight*. The argument that disputes would arise, is not a business view of the question: we have abundant cause of dispute now. It is evident that bargains by weight make the seller careless and the buyer less strict. If the seller deliver the bulk inferior to sample, of course the buyer is prejudiced. It is most decidedly an indirect permission to do so, if the corn is made a certain weight: it is a premium for slovenly management. I see farmers generally make the sheaves too large; and in two or three days, the corn is removed to the barn or rick. The consequence is, the first six months after harvest, English wheat will not make a good sack-flour; and millers

are obliged to have recourse to strong Baltic or other foreign wheat, at a cost of generally 5s. to 15s. a quarter more than home-grown. The winnowing also is generally very carelessly done. Now, I believe this carelessness is induced in a great degree by the *selling by weight*, which I, therefore, protest against as an injury to the miller, more so to the baker and the public, and a national disadvantage. The imperial bushel, with a guarantee of the natural weight, is the best guide; and if the weight is not stated, we use our judgment; and, if foolish enough to overestimate the quality or weight, it is no fault of the seller. We should then buy inferior quality at its relative value; and the tithe would be fairly charged, with a uniform measure throughout the kingdom." In these remarks he entirely concurred. In conclusion, he would observe that, so long as such an anomalous clause as the 6th clause of that act continued on the statute-book, there could be no uniform system; and, in his opinion, they should, at all events, petition the Legislature not to continue to stultify itself by a clause so inconsistent with the manifest intention of the act.

Mr. ACTON (of the Temple) said, there could be no doubt from the turn the discussion had taken that measure was the prominent mode of selling corn in the Eastern and Western counties, whilst weight seemed to prevail in the Northern and Midland districts, and although he agreed with Mr. Sidney that there ought to be some uniformity in London to guide other markets, owing to the rapid advances of steam transit, he should vote with Mr. Baker and the *wise men from the East* for an improved measure. We had lately heard much of one great social evil, which was very difficult to deal with; but not so with another one which hinged on this question, viz., the prostitution of common honesty towards the poor and needy, in many of the districts around London, and especially in the one he resided in—Camberwell. Now, if a deputation went up to the Government in this matter, he would suggest that a more general supervision of weights and measures should be enforced than at present, and that the fair day's wages for a fair day's work which that Club wished to enforce, should not be frittered away by the iniquities which now daily took place in poor neighbourhoods.

The CHAIRMAN said he had only a few words to offer in closing the discussion. Like Mr. Baker, he was very sorry to differ from his friend Mr. Wallis; but he must declare that he was certainly in favour of measure which had prevailed in his own county (Berkshire) for a very long period. He had no wish, indeed, to deny that what Mr. Skelton advocated, namely, measure with a guaranteed weight, might be an improvement on measure alone, and he thought such a system would be generally acceptable in his own county. Having, however, made numerous inquiries in the district to which he belonged, he was convinced that while there would be no objection to the system which Mr. Skelton advocated, there would be the stongest objection to the simple use of a standard weight. Not only are the tithe rent-charge and corn rents, but all the valuations which took place throughout the country were based on measure, not on weight; and he was sure that valuers would have the greatest difficulty in arriving at correct conclusions if weight were substituted for measure. Moreover thrashing and other operations of the farm were regulated by measure; and he thought the establishment of measure as a universal rule would interfere far less with all existing customs than the establishment of a standard weight. He quite agreed with preceding speakers as to the desirableness of adopting, if practicable, some uniform standard for the sale of corn (Hear, hear).

Mr. WALLIS then replied: Notwithstanding, he said, all that he had heard to the contrary that evening, he was still of opinion that weight was far preferable to measure as a uniform system; and if there were to be any change at all, it was of course desirable that it should be a change to the best system that could be adopted. The majority of persons interested in the matter were manifestly in favour of weight, which was in very many places entirely superseding measure. What Mr. Skelton advocated was, in fact, selling by weight.

Mr. SKELTON observed that it was a uniform weight that he objected to.

Mr. WALLIS continued: The bushel varied with almost every sample; and to call it a standard, therefore, was altogether a mistake. It was quite certain that the country could not now go back from weight to measure, and therefore if there were to be a uniform system it must be based on weight.

Considerable discussion ensued as to the form in which the question at issue should be submitted to the meeting. Ultimately,

Mr. WALLIS proposed, and Mr. B. WEBSTER seconded, the following resolution:—"That it is the opinion of this meeting that a standard of weight is preferable to a standard of measure."

Mr. SKELTON moved, and Mr. LITTLE seconded, the following amendment:—"That all sellers and buyers of corn in this kingdom should come to the conclusion to petition Parliament to enforce a uniformity of measure of 8 imperial bushels."

The amendment, after having been seconded, was put from the chair, when 13 hands were held up in favour of it, and 13 against it. The chairman then gave his casting vote in favour of the amendment, and the effect of this was of course to carry it. As the original resolution involved the same question as the amendment, and had virtually been negatived, it was not submitted to the meeting.

On the motion of Mr. WOOD, seconded by Mr. THOMAS, of Bletsoe, thanks were voted to Mr. Wallis as the introducer of the question which had been discussed.

Mr. WALLIS, after acknowledging the compliment, expressed his regret that the decision of the Club on the subject which he had brought forward was not in accordance with the opinions of the majority of farmers and corn merchants, adding, that he was not without hope that the time was not far distant when a very different view would be taken of the matter, even in that room.

On the motion of Mr. GREY, seconded by Mr. WALLIS, a vote of thanks was given to the Chairman; and, after a brief response from that gentleman, the meeting separated.

HALESWORTH FARMERS' CLUB.—The members of this Club have been engaged in an interesting discussion on the "Principles of Rating." The question was introduced in an able speech by Mr. J. Howlett, of Wisset; and the discussion which ensued extended to considerable length. We must content ourselves with recording the following resolution, which was unanimously adopted: "That the principles of rating having undergone a lengthened discussion, it is the opinion of the members present that, in order to secure one uniform rate, as prescribed by Act of Parliament, the several boards of guardians throughout the country should be vested with full powers of correcting not only any inequalities which may be presumed to exist as between parish and parish, but also as between their respective unions; and further, that all poor-rates should hereafter be levied and made by the authorities so constituted, instead of by the different churchwardens and overseers."

THE IMPERIAL BUSHEL THE BEST STANDARD MEASURE.

The difficulties to be encountered in arriving at any uniform system of Weight or Measure in the sale of corn were very forcibly illustrated at the February meeting of the Farmers' Club. Of course, the great advantage of a central body like this is, that it combines the opinions and experience of almost every part of the country. The uses of such a power could never be more apparent than when applied to the consideration of the subject here brought under discussion. Any merely local Society — be it a district Club, a Board of Guardians, or a Corn-market Committee — would, and have, most probably, made very short work of such a question. They would just resolve and recommend in accordance with their own habits and practice. Let the uniform standard be their own; let everybody come round to this, and then we shall do very well. At the London Club, however, nearly every man represented a district, and, more or less, a system of his own. Indeed, we really believe that, when at last a definite motion had to be put, there was scarcely a member present but who, had the opportunity been allowed him, would have proposed, amended, or suggested something a little different from that of his neighbour—A neighbour, be it understood, sitting in the next chair to him at the meeting, but coming from quite another quarter of the kingdom. It is, we must repeat, such component parts as these which give peculiar value and importance to the proceedings.

Under these circumstances Mr. Owen Wallis' well-arranged tables and careful series of results told by no means so strongly as might, perhaps, have been expected. It appeared to signify very little what the Dolgelly Union or the Arundel Farmers' Club thought about the matter, as everybody came manifestly prepared to think for himself. Mr. Wallis, in fact, did not read the digest of evidence we give in our report. With very sound discretion he contented himself with stating what the tendency of this was, and how thoroughly he agreed with the majority. Everybody, as a rule, insisted on the necessity of uniformity, either of weight or measure; while a far greater number of the opinions thus collected were recorded in favour of sale by weight. In the discussion, on the contrary, the preponderance was the other way. The two most able and suggestive of all the speakers who followed the introducer of the subject were Mr. Robert Baker and Mr. Spencer Skelton, and both these advocated a measure of capacity; or, in other words, the more general recognition of our present standard, the imperial bushel. There is no doubt, either, but that the addresses of these two gentlemen had considerable effect upon the audience, and that they are mainly responsible for the conclusion arrived at. Figures and tables do not go for much, on occasions like these; but a good plain argument is sure to make its way.

When the Central Club, during the past year, took up this question, certain of the leading members resolved themselves into a special committee. The opening of Mr. Wallis' address will show what steps they took to put themselves in communication with the country, while his paper may be regarded as embodying the sense of this correspondence. Previously, however, to issuing their circular, the committee started with two propositions, which they severally moved, passed, and eventually embodied in their public letter. The first of these formally declared, "That a uniform system of weight or measure for the sale of corn is desirable." The second stated more definitely, "That this Special Committee feels justified, from the communications received, as well as from the opinions expressed, in recommending the sale of corn by weight as the best means of establishing uniformity of system in the sale of agricultural produce." Now, it will be found from the conclusion arrived at on Monday evening, that a general meeting of the members have corrected this opinion of their committee. In the face of the increased evidence in favour of weight, a majority, with the Chairman to head it, have declared themselves in open council for the imperial bushel. This is pretty sure to be regarded in many different ways—as stultifying what has already been done—opposed to the general feeling of the country, and so forth. There was some little demur as to the order in which the resolutions were put; but considering that Mr. Skelton's amendment was clearly carried, we do not see much to complain of. It should be explained that many members had left before the division took place; not that we think, had this been asked for earlier, would there have been any other result.

We shall venture even a little beyond this, in saying that we see nothing whatever to complain of, in such a termination to the proceedings. We consider it to have been the most practical determination that the Club could possibly have arrived at. We believe that, if in our generation, we are to have any uniformity of system, it will be accomplished only by the imperial bushel. We have some reason for thinking that if the Government does interfere, in answer to the wishes of the country, it will be only to more rigidly enforce its own standard. We are very sanguine that by such a means the object is feasible. On the other hand, a measure of weight is positively hedged in with obstacles. The Government will not merely have to ignore the principle it has so far maintained, but to upset and revolutionize with this many a subsequent measure engrafted upon it. There is the Tithe Commutation Act, riding easily and pleasantly at last—all to be done de novo. There are our corn rents, and so forth, all to be fresh arranged. And there are the many districts—in the majority, as we imagine—which are now accustomed to the imperial bushel, and the fact of eight bushels making one quarter, to be untaught, and then schooled over again, by the same master!

It is not our purpose to go very minutely here into the merits of the two systems. The decussion will show that much may be said, for and against either. A farmer's man, according to Mr. Wallis' experiment, cannot measure up a bushel of corn twice alike—so much for measure; while by Mr. Baker's story, a miller can *guess* nearer to the weight of a sack of corn than ten farmers can actually weigh it to—so much for weight. Perhaps, after all, the better plan would be, as is now often done, to combine the two, and deliver a *bushel* of corn of a *certain weight*. Call this what we may, a measure of capacity or of weight, it has the recommendation of going for its fixed standard to the already acknowledged one of the country. By such a path we might hope to find our way out of this difficulty. By any other we fear we should only become involved in a labyrinth that few would care to help us to explore.

In the hands of our rulers this resolution of the

Farmers' Club should, in short, be a strong and ready weapon. The whole country demands uniformity; and when you gather together the delegates of the whole country, who offer you evidence quite as valuable as that you would obtain by the slow, tedious process of a committee, what do these ask you to do? Is it the dangerous or costly experiment of a new system? Is it something that the people know little of, and that they will take to with proportionately little liking? Nothing of the kind. The buyers and sellers of corn simply request that you will be good enough to stand by your own act. You have said there should be an imperial bushel by which all such transactions should be regulated. Granted. We are willing to obey the law if you are only ready to enforce it. There is an old joke against a certain county member who drew up a most meritorious measure, but who forgot to insert any penalty for its non-observance. In this instance the framers of the bill would appear most carefully to have "provided always" that people should not use the imperial bushel without they cared to.

We shall obtain no uniformity by such half-measures as these. What the country simply wants is "the Bill, the whole Bill, and nothing but the Bill." Let the question be argued as it will, there is no doubt but that we are becoming more and more accustomed to the imperial standard; and its general enforcement would be attended with little inconvenience or annoyance. Comparatively, there is no other such a means so ready to our hand; and we cannot help thinking that the Farmers' Club resolution will stand as a tolerably good finger-post. It points to the safest way and the shortest.

ON THE TRANSFUSION OF BLOOD IN THE HORSE.

By Mr. James Farrell, V. S. to the Lord-Lieutenant and Constabulary force in Ireland.

During the autumn of 1856, and spring of 1857, an epidemic prevailed in and about Dublin; indeed, I believe, all over Ireland, to a greater or less extent; which at its outset presented the leading features of influenza, but of a low typhoid character; it was much more prevalent along the eastern coast than on the western, or in the midland counties. In Dublin it was very fatal, and in most of the cases which I was called on to see I found intense debility, which in some instances had come on within a few hours after the disease had first manifested itself. Horses were seen to eat their food in the morning with every appearance of health and good spirits, and before evening they were found resting against the side of their stables for support; so rapidly had debility followed the first symptoms of the disease.

With all these cases the principal difficulty was to support the strength, watching at the same time closely the symptoms which manifested themselves as the case progressed. Sometimes the urinary organs became affected, and repeated evacuations caused the patient to sink rapidly. In others the bowels were involved, and to such an extent as to resemble bad cases of cholera in the human subject; but the worst forms of this disease that I witnessed were those in which the animals had been bled previously to my having seen them. With those cases which had not been bled, I had, in treating them, an average amount of success; but in most of those that had, I am bound to admit, I was by no means so fortunate. I found that everything I could do to restore the vital powers was, in the majority of cases, useless, and, save in the instance of some young, vigorous horses, collapse set in within a few hours after the abstraction of the blood.

I gave a fair trial to all the usual remedies. In cases where influenza had assumed a typhoid form, and in which the leading symptoms were a feeble, thready pulse, quick and laboured breathing, cold extremities, clammy mouth, drooping eyelids, utter prostration of strength, and, in short, the usual symptoms of collapse, especially such as had been reduced to this state by loss of blood, or by excessive purgation, I was generally unsuccessful. Discouraged by repeated failures, I determined to try the effect of "transfusion," believing it to be a not unnatural restorative, especially in cases where the improper abstraction of blood had superinduced the symptoms above alluded to.

To enable me, therefore, to give this operation a fair trial, I commenced a series of experiments, so as to discover the simplest, safest, and most effectual method of conveying blood from one animal into another: I first tried the transfusion syringe, which has been used by medical practitioners for this purpose; but, whether from want of skill in its use, or from some defect in the instrument (which had been recommended to me as one of the best), or from some other cause, I cannot tell, but certain it is I was in no case so successful with it as I was with a more simple apparatus. I fancied that the blood lost much of its vitality by being exposed to atmospheric action, and also by its being forced and compressed within the cylinder of the instrument. These impressions as to the cause of failure induced me to undertake several experiments, with a view to the construction of an instrument which would fulfil the requisite indications, viz., to allow the blood to pass freely from the vein of the healthy into that of the diseased subject without coming in contact with the atmosphere, and without alteration of its temperature. I at length adopted an exceedingly simple apparatus, which may be described in a few words. It consists of an india-rubber tube some two-and-a-half feet in length, and three-eighths of an inch in diameter—that is, about the calibre of the vein in the adult horse. To either end of this is fitted a silver tube, curved somewhat like a syphon, so that the end, which is slightly rounded at the point, might be passed easily into the vein, both tubes being exactly alike. A narrow zinc or tin trough is required to contain hot water, in which two-thirds of the tube should be immersed during the time that the blood is flowing. This completes the apparatus, and, being prepared, and the horses ready, held by assistants, the jugular vein of the healthy horse, from which the supply is to be taken, may be opened, and into it one of the silver tubes carefully passed, point upwards, so as to receive the current of blood as it flows back from the head; the operator holding the other end, and, having previously opened the corresponding vein in the patient, he should wait till the current is passing freely down the tube from the healthy horse, and then bring it in contact with that which is now flowing slowly from the patient; he should pass the end of the tube carefully into the vein, point downwards, by which means the possibility of any air getting into the tube is avoided. The quantity to be transfused is readily ascertained by watching the expression of the eyes, and noting the pulse carefully. So long as there is no dilation of the pupils, and so long as the heart's action is not very much affected, the blood may be allowed to flow on uninterruptedly; but as soon as the pupils become dilated, it is necessary to lessen the supply gradually, by compressing the tube with the finger and thumb. If the dilatation disappear after a minute or two, the blood may be again allowed to flow; but if it increases, further transfusion must be stopped, or otherwise injurious consequences will result. In the cases of two animals which I purchased for the purpose of experiment, I purposely allowed the blood to flow after the dilatation of the pupil had manifested itself, in order that I might see the result; and I found it to increase: and in one of the cases, after winking both eyes three or four times in rapid succession, the horse reared up, and fell back. In the other case, I forced the blood in from an india-rubber enema bottle. The pupils first became still more dilated, the breathing very quick and difficult; the eyes assumed a wild, agonized look; and the animal, with a sudden bound forward, fell dead. I had my finger on the artery during the entire time, and observed a great unsteadiness and fluttering of the pulse, which increased in frequency until the instant before he fell. In the first of these cases I did not force the blood into the vein, but allowed it to flow until I perceived the injurious

effects on the horse. He tottered and fell, but in a short time recovered, and was walked back to his stable. He died in the course of the night; and, on examining his head next day, I found considerable congestion of the brain. The tube used for these experiments transferred about three quarts of blood in eight minutes—at least, so might be inferred from the fact that, when used as a syphon, it passed three-and-a-half quarts of water (and a little less of oil) from one vessel to another in that time.

In one of my successful cases, *phlebitis* supervened both in the healthy and diseased horse. I think I am correct in saying that this disease is by no means so likely to occur in horses as in human beings, and is certainly not so formidable; but, nevertheless, I am quite sure that it may happen as a consequence of the operation, if the instrument be not kept scrupulously clean, and also if great care be not taken in its introduction into the vein. Having, from these and other experiments not necessary to detail, determined on the mode of operating most likely to be successful, I shall now proceed to state the result of four cases in which I have operated, and which I think I may look upon as having been followed with entire success. In three of the cases, the patients had been bled a short time previous to my having seen them, and were so much weakened that they could scarcely walk. In the fourth case, a drastic purgative had been administered, causing super-purgation and great prostration of strength. In each of the four cases, the condition of the patient was so similar, that the description I have already given may answer for all. Having selected a healthy young horse, from which to obtain the blood to be transfused, I opened the jugular vein in the patient and in the healthy subject; and having inserted the tube, as before described, into the vein of the healthy horse, I placed the Inida-rubber tube in the tin trough containing the hot water to maintain its temperature, and the other curved tube into the descending portion of the vein in the patient. As soon as the current from the healthy horse had completely expelled all atmospheric air, the instrument being thus arranged, the blood flowed freely from the vein of one horse into that of the other in an unbroken current. The average quantity of blood transfused in each of these cases was about three quarts. I observed no particular symptoms to follow from the transfusion, until two quarts or more had passed from the healthy to the diseased subject; but as soon as about that quantity had flowed, there appeared to be produced an amount of stimulation indicated by an increased action of the heart; at the same time the pupils began to dilate, and the countenance evinced an anxious expression. My former experiments led me to watch with great care the progressive dilatation of the pupil, and I deemed it expedient in each case, when this symptom was well developed, to compress the tube so as to diminish the current and allow the transfusion to proceed more gradually and slowly. Occasionally I almost completely interrupted the current until the subsidence of this symptom; and I found that, when about three quarts had been transfused, any additional quantity was followed by unpleasant symptoms, which indicated the necessity of stopping the operation. On removing the tube and closing the vein, all symptoms of irritation gradually subsided; and the pulse, from being rapid and irritable, became slower, stronger, and fuller, gradually approaching the healthy standard.

In each of these four cases the reaction was steady and progressive. The natural warmth of the extremities was gradually restored; and in the course of ten or twelve hours the patient presented other equally unmistakable symptoms of amendment, such as returning appetite, more quiet and steady respiration, cheerfulness of countenance, and a willingness to move about: from this point there was a gradual improvement, and in a short time they were pronounced cured.

I have been induced to submit these few remarks, much less with a view to record any little success I may have had in performing the operation myself than with a hope that others, far more capable, will take up the matter and test it thoroughly; for whatever obstacles and objections there may be to its performance in the human subject, there are none to prevent its becoming a most valuable agent in veterinary science.—*Dublin Quarterly Journal of Medical Science.*

MR. POPPY, OF WITNESHAM.

TO THE EDITOR OF THE IPSWICH JOURNAL.

DEAR SIR,—The letter which I enclose was addressed to me at the Grundisburgh Farmers' Club, on Monday last, and read at the meeting. The members who were present were unanimously of opinion that a subscription should be immediately entered into, in behalf of Mr. Poppy, and they thought it advisable that his case and claim to the sympathy of the agricultural community should be made known through the columns of your *Journal*, the *Suffolk Chronicle*, and the *Mark Lane Express*.

I fully concur in the statement made by Mr. Biddell, and I earnestly hope that steps will be immediately taken to assist the worthy promoter of agricultural progress.

I am, dear Sir, yours truly,

G. D. BADHAM.

The Sparrow's Nest, Jan. 27, 1858.

MY DEAR SIR,—May I beg of you, as president of the Grundisburgh Farmers' Club, to lay before the meeting the present position and circumstances of Mr. Poppy, of Witnesham, and his claims to the sympathy of those who have been interested in the prosperity of agriculture.

Forty-five years ago, and long afterwards, no man did more, nor hardly any half so much, in proportion to their means, as he did, to promote the general cultivation of Swede turnips and mangold wurtzel—proved now to be the most valuable roots introduced in farming within living memory. I remember the exertions he made, year after year, to convince farmers of the value of beet roots. He set the example of growing them in his fields. He induced persons (myself amongst others) to send stock upon his land to eat them, to prove their value. He distributed seed in several counties, and wrote about them in pamphlets and newspapers; and I believe the general growth of swedes and beet in this county was many years earlier on account of Mr. Poppy's exertions to bring them into notice. I never heard of the white Belgium carrots till they were brought from that country (or France) by Mr. Poppy many years ago (probably upwards of thirty). His experiments and publications on securing Swede turnips from flies, procured him a gold medal from an eminent distant agricultural association. Upwards of thirty years ago, he urged the advantages likely to arise from country farmers' clubs, and was chairman and principal manager of the first established in this county—that at Ashbocking—from whence arose, directly or indirectly, those of Framlingham, Halesworth, Harleston, and others, which had the advantage of his correspondence. His experiments and writings to preserve young turnips from flies, and his examination of expedients that have been tried to effect that purpose during the last thirty or forty years, deserve notice; but particularly his recently proving (so far as two or three years are proof) that drilling only two or three rows of thick mustard will effectually preserve a whole field of young turnips from flies. This discovery is entirely Mr. Poppy's; and, assuming it to be effective, is of incalculable value to the farming interest. He has never had an interested motive in what he has done, beyond the wish that others might profit by his experience.

Under these circumstances may I beg that you will propose to the meeting some moderate subscription for him, and promote that object in any way you may think advisable. Mr. Poppy is now at the age of eighty-five, and his wife nearly eighty. They are living in a cottage, respected by all who know them, upon very small, precarious means, insufficient for the common requirements of comfortable humble life.

My state of health prevents my rendering you any assistance in forwarding the object I have mentioned, but I shall be happy to receive any contribution which may be forwarded to me for Mr. Poppy's benefit. It is much to be wished that some of your influential friends may co-operate with you in getting up a subscription as the reward of merit for Mr. Poppy, in a wider circle than the respectable club over which you preside.

I am, my dear Sir, with every respect,

Yours sincerely,

Playford, Jan. 25, 1858. ARTHUR BIDDELL.

[We need not say that we shall be happy to do anything in our power to promote the object of Mr. Biddell's letter,—EDITOR FAR. MAG.]

FARMYARD DUNG: PREPARATION AND APPLICATION.

No subject in the varied course of agriculture obtrudes a more general notice, or deserves a more important consideration, than the application of farmyard dung. The article is produced on all lands on which grains grow and animals are kept, and is the most efficacious of all manures that are yet known. It is a mixed body of straws and excrements, urinary and solid, possessing the quick action of the latter substances, and the more durable qualities of the former materials. All other manures are brought from foreign places, and purchased by a ready cost; farmyard dung is daily produced, and of a constant repetition. The use is varied and of a great value, and the application is no less important.

An approved and long-continued mode of preparing farmyard dung prevails in the celebrated turnip-growing Border counties, of placing the contents of the cattle yards in square piles about six feet in height, in the corner of the fields to be planted with green crops. The yards are concave or dish-shaped, retaining and spreading the moisture equally over the mass, and supplied with straws that absorb all the moisture from rains, snows, and urine. The contents are carried out at two different times during winter, and no pressure is allowed on the piles, except the weight of one or two persons to spread the materials evenly and thinly over the heap. In this condition, a fermentation reduces the heap into a saponaceous mass for use in May and June, and in a condition that is easily divided by hand-forks, well moistened, and from which the heat of fermentation has in most cases nearly altogether vanished. Much bulk is lost by this mode of preparation, but it is reckoned the best for the use of green crops.

Having been educated under the above system of preparing farmyard dung, I practised the mode with the usual success in various parts of the kingdom. In later years I adopted another mode, from the observation of a very large loss of bulk, and from a wish to use a fresher condition of the dung. At any times of convenience during winter, the contents of the yards are carried to the green-crop fields, and laid in a heap sloping at both ends, over which the carts pass to deposit the loads, and over which the materials are spread evenly and thinly, in order to mix the substances, and that no part remain in a dry state. The consolidation from the pressure of the carts prevents the fermentation of the heap, which is formed at convenient times, from November to the month of April, and later when the yards are duly moist and the straws thinly used. Potatoesare the first-planted green crop; and about ten days before the dung is required for use, the heap is turned over with forks, laid loosely together, and the lumps well broken, and the dry outside of the heap thrown into the middle of the new aggregation. A very active fermentation immediately commences, which is prevailing during the deposition of the dung in the drills, which are immediately reversed and the seed sown. This mode produces fully equal if not superior results to the first-mentioned preparation: it affords a larger bulk, and more convenience in forming the heaps at different times; while the former requires to be done at one time, or not at distant periods.

For some considerable time past, I have doubted the fermentation of farmyard dung, having had freshly-voided fæces, carried from the cow-shed, laid into drills for turnips, which were a superior crop to the parts of the field treated with fermented dung. This result happened on several occasions, constituting a fact, from a majority of similar results. In order to facilitate the application of fresh dung, I have long ago recommended that all straws for litter should be cut into short lengths by the thrashing machinery, and that the dung be mixed with the prepared turnip-lands by contrary workings of Finlayson's harrow, and raised into ridglets by one furrow of the common plough, in which the seeds are sown by the common two-drill machine, or with a portion of bones or guano by Hornsby's drop drill. This practice will supersede the fermenting heap of farmyard dung, and remove the objection of long straws not covering into the ground, by cutting into short lengths. The fæces and short straws will be convenient for Chandler's liquid manure drill, when Mr. Kemp's theory has advanced into a more general notice.

The application is most excellent of farmyard dung as a top-dressing of young grass seeds; and for that purpose, the fresh, strawy condition is preferable. The crops of clover are largely increased, and also the following crops of wheat. I have long ago suggested that the farmyard dung generally applied on bare clay fallows, for wheat, be applied as a top-dressing on the young wheats, in March, by means of moveable timber railways placed on the ground. But, most unfortunately, now-a-days, no opinion, theory, idea, or suggestion meets with any notice, except it emanates from a society or a club. Individuals languish in obscurity, and are held in insignificance.

The use of food being to produce caloric to plants and organic bodies, the chief consideration is, how to apply the manures as food for that purpose, and, in order to yield that element in the least expensive manner and most ample quantity. I wholly dissent from chemistry —that rotten dung is more efficacious than fresh dung: weight for weight, and quantity for quantity, the latter must prevail in the abundance. The many statements made, of chemical agencies and transformations, are of small account.

With regard to covered and uncovered feeding-stalls, the former may suit in certain places; but in the majority of situations, the straw could not be reduced without the rains and snows that fall in the yards; and, under the covered sheds, the want of moisture produces a dry putrefaction. Even with the present open yards, much difficulty is experienced in reducing the straws into an impregnated condition with rain and urine.

I have not the pleasure of an acquaintance with Mr. Baker, of Writtle, nor do I know his appearance from sight; but I have ever admired the sound and enlightened judgment displayed by him on all practical subjects, and the strong sense that he brings to bear on the reveries of cognate auxiliaries. These aids are but puny, shallow, and evanescent; apt to dazzle and deceive, to bewilder and mislead; and often noisy as the tinman's trade. An enlightened practice must lead and confirm.

J. D.

KENNINGTON AGRICULTURAL AND CHEMICAL COLLEGE.

LECTURES ON THE GENERAL PHENOMENA OF THE EARTH, HAVING REFERENCE TO THE PRODUCTION AND MAINTENANCE OF ORGANIC LIFE.

BY CHARLES JOHNSON, ESQ., PROFESSOR OF BOTANY, GUY'S HOSPITAL.

LECTURE XIII.

While the minuter forms of the Alga are continually employed in preparing their aquatic abode, whether sea or river, lucid lake or turbid pool, for the development of higher grades of vegetable life, parallel creations on the land are equally active to a similar end, working alike unseen, and even unsuspected in the earliest fulfilment of their functions. These are the Lichens, the first in our classification of terrestrial plants, and the natural precursors of the groups which follow on the scale. The cause of their first appearance, in any particular locality, is as much of a mystery to the human observer as is that of their aquatic brethren; though, as in the case of the latter, their after-propagation is the result of laws, the action of which is generally recognized in vegetation of a higher grade, however insufficient theory may yet have proved to its elucidation.

Let us examine the history of Lichen production and successional development—not critically, and under the influence of philosophical prejudices, which too often tend to lead us to false conclusions, but, as it may be read on the page of Nature. A newly-bared surface of rock, or sand, or soil, a brick or tile, nay, even a pane of glass, exposed to air and light, becomes the resting-place of myriads of microscopic atoms, which enlarge and multiply their kind; that kind is the simplest organism imagined or recognized by human senses: it is the cell again; the *cell* is the plant itself, developing the *cell* its germ, its beginning and its end the same. Such is ever vegetation in its earliest appearance, where organic elements are wanting for the production of a higher or more complicated frame; and our microscopic atoms are the first colonizers of the hitherto barren spot of earth—the pulverulent Lichens. We may pause awhile, to speculate as to whence they come. The minuteness of the germs—(seeds we will call them, though the botanist may cavil about the term)—of these little plants, is such, that the lightest movement of the air may dislodge, and bear them to incalculable distances; and, without exaggeration, we may assume that, like the moisture which is mingled with the atmosphere as viewless vapour, they may be constantly present throughout its whole expause, be inhaled with our breath, and distributed with every wind that blows. I am not, in this assumption, violating the compact just made, at the commencement of the present paragraph, to avoid for the moment all mere theory, and examine fact as it exists, alone and without bias. The origin of a living being is required; and when we note the successors of such being making their appearance under circumstances of universal operation, we are justified in seeking a corresponding source for itself. The doctrine, ascribing the apparently spontaneous development of individuals, belonging to the lowest classes of vegetation, to this constant presence of their seeds floating in the atmosphere, cannot be proved to demonstration; but when we learn that certain of the simpler forms of fungus, as mould, &c., are found in the diseased tissues of living animals, and only upon such as are exposed to contact with the air, as upon the surface of their bodies, or in the air-cells and tubercular cavities in the lungs, as well of mankind as of the inferior animals, their origin surely is too evident to admit of misconception: wherever seen, they are the produce of such air-borne germs, which require only a resting-place to commence the career of growth and reproduction.

Linnæus, comparing, in a fanciful mood, the aspects and functions of the individuals composing the great natural families of the vegetable kingdom with the several grades of human society, bestowed the Latin title of *Vernaculi*, or bond-slaves, on the Algæ; under which denomination he included both the plants so called by modern botanists, and the Lichens, the relative structures of which seem to have been prefigured in his mind at a period when microscopic research had yet done little or nothing towards the elucidation of such resemblances. The title is, as observed by the late Professor Gilbert Burnett, of King's College, London, peculiarly appropriate to the Lichens, "which are, as it were, chained to the soil they labour to improve for the benefit of others, though from it they derive no nourishment themselves." The latter assumption is, in most instances, probably incorrect, as may appear from our coming inquiry; a circumstance, however, that does not greatly interfere with the justness of the comparison.

The modern system of farming by rotation crops, superseding the antiquated process of fallowing, is only the adoption of principles constantly in action under the government of Nature; and the history of the little plants before us strongly exemplifies a fact, of which our stubborn ancestors, and even many of their less-informed successors, were long in becoming convinced, namely, the influence of the unseen and intactible upon the visible and tangible. The necessity of accumulating the proximate elements belonging to the higher forms of life, before the introduction of the latter upon the face of the world, has been already remarked upon, in one of our previous lectures; and where are the constituents of these compounds, the true elements, to be found? whence are they to be elaborated, but from the rock, the air, and the water, each in itself incompetent to their necessary elaboration! Life must precede life. This is the grand law under which organic being, once produced, can alone be maintained; a law enunciated when creation was an act, and which has remained such since that act was fulfilled. No chemical manipulation of the inorganic atoms of the fire-tempered granite or greenstone produces the required compounds of animal and vegetable substance; the vital principle alone being capable of adjusting their proportions, modifying their affinities to such a purpose, and eliciting the mysterious combinations. The modern practitioner in that glorious art, which seems to sport with the elements of simple matter, bidding them unite and separate at will, fails in this. True! he can arrange and disarrange the organic atoms, force them to assume a different form, and, so long as they remain organic, control results, even as he acts upon the mineral; but he has no producing power. He may call forth the starch, the sugar, that did not exist as such before; nay, even the odours of the rose and of the violet, where no flowers are at hand to yield them. But, the products of organization, that are here his playthings, are only compelled into action under their own affinities with surrounding matter; and those affinities, once overcome, once unbound, his power over them as organic elements ceases, and a renewed subjection to the laws of life alone can restore them to their former condition.

In contributing to this recurring change and recomposition, every member of both animal and vegetable kingdoms is constantly and actively employed, as a necessary consequence of its existence. But, their mutual operations are too complicated to admit of separate examination, beyond the point of commencement, and a few stages upward upon the scale. On the land, the lichen is, as heretofore remarked, the earliest perceptible agent. But it may be inquired, What is a lichen? The question is as simple and pertinent as might be, What is a grass, a flower, or a tree? but is less easily answered so as to be satisfactory to the uninitiated. The botanist defines a lichen to be a "perennial plant, often spreading over the surface of the earth, or rocks, or trees, in dry places, in the form of a lobed and foliaceous, or hard and crustaceous, or leprous substance, called a thallus, &c., &c." Will this definition

answer our purpose? As it is to be feared not, we will try again. The lichens I have before described as constituting a numerous and diversified tribe, and no general definition will convey an idea of what they are in the aggregate. Their simplest forms are seen in the several species of Lepraria, so termed from the Greek *lepra*, scurf or leprosy; and the most common and universally distributed of these, is the green powder, that, in all parts of the country, makes its appearance upon the walls of old buildings, park-paling, and the trunks and branches of trees. A magnifying glass shows it to consist of minute globular or oval grains, closely clustered together. These are the single microscopic cells of which mention has been already made; and the uncertain limits of the lower groups of vegetable life are instanced in the fact that this *Lepraria viridis* has been referred alternately, by different botanists, to the algæ and to the lichens. It is a point of little moment, so far as our present purpose is concerned, to which group it really appertains, as both it and its brethren of similar simple structure and habit are equally pioneers of vegetation. Conspicuous on the objects and in the situations just mentioned, they are no less common on the ground everywhere, where their propagation proceeds more rapidly on exposed and newly-turned soil than among growing crops. To the student of Nature, who thus observes them, it would be an absurdity to deny that their appearance is associated with a function: our common parent admits of no sinecures, no superfluous offices, under her government; whatever is, must act or cease to be; presence is inseparable from need; and the living microscopic atom must work, or die and become the medium of support to others.

The powdery lichen, unseen by the cultivator, or unregarded and despised as is the dust on which he treads, is truly a valuable *bond-slave*, pursuing a slow, but unintermitting toil for his benefit, and elaborating the first organic compounds of hydrogen, carbon, and oxygen, that are destined, on its decay, to become the basis of a higher vegetable form. But it is not within the limits of an agricultural district that we are to expect to see any striking manifestation of the lichen fulfilling the purposes of its existence. We must ascend the mountain towards the verge of perpetual snow, examine the smooth worn surface of rocks recently abandoned by the sea, or walk over the scarcely-cooled lavas of some volcanic region, to trace the progress of primeval plant-development, and learn to admire, and estimate at their true value, the operations of these its hardiest pioneers. The investigator of earlier lichen history must set aside all previous views of vegetable growth, as associated with the necessary presence of soil and root-extension. The barest, nay, almost polished surface, to which adhesion would seem scarcely possible, yields a sufficient resting-place: the imperceptible moisture of the driest atmosphere affords the required medium of sustenance. Many of the tribe appear in the form of a white or grey powder only, and bear so little resemblance to organic substance, that a person unaccustomed to the study would, in most instances, mistake them for casual stains upon the surface of a flint or a saline efflorescence on a mass of granite; indeed it often requires no small degree of familiarity with the general structure of the family, and a glass of high magnifying power, to distinguish some of them from the rock or earth on which they grow. The decay of these minute and obscure kinds, however, affords a thin stratum of soil sufficient for the habitation of other species of more complicated organization, larger size, and more interesting appearance. Some of the higher grades of lichenaceous plants are remarkable for their beauty, elegance of outline, and diversity, as well as brilliancy, of hue.

The remark of an author previously quoted—that, while lichens improve the soil for the benefit of other plants, they derive no nutriment from it themselves—is apparently opposed to circumstances attending their development, different species being found on different substances. This fact is especially instanced in those which are most conspicuous, giving colour to rocks, trunks of trees, walls, and buildings; many of them ranking among the highest forms of their order: and the practical botanist is well aware of the preferences they exhibit. The various primitive, secondary, and igneous rocks yield resting-places to particular species; and so invariable is the attachment of certain kinds to peculiar media, that the geological collector may often determine, by the hue of its surface, clothed with a thin coating of primeval vegetation, the nature and composition of the rock he is approaching. Granite, slate, sandstone, limestone, trap, &c., are each likely to be thus distinguished; and in a similar manner the greater number of the epiphytic lichens, or those which grow on the bark of trees, are not indiscriminately scattered upon the stems of different species constituting the forests of the same climate, but vegetate exclusively upon the surface of those which afford them the necessary texture to which Nature has adapted their powers of adherence. A skilful landscape-painter, observing the effect thus produced, adapts his colours, accordingly, to the trank of any particular kind of tree he may be desirous of representing. He sees that of the oak invariably differing from that of the beech in the hue of its humble dependants, that of the elm from that of the willow, and so on of others; and so perceiving, his picture becomes a transcript of reality.

This preference of the lichenaceous plant for specific *habitats* is without doubt associated with difference of texture; but it is no less unquestionably attributable to other causes likewise. The lichen, as a cellular vegetable organism, derives much of its subsistence by absorption from the atmosphere, in the same manner as the alga does from the water in which it is submerged; but the elements held in solution by the former are insufficient to supply certain principles which are invariably present in the plants now before us. They must be obtained from other sources; and the succession in which the species appear, following each other always in a corresponding series, is a further and unmistakeable manifestation of the fact. Metallic oxides (that of iron especially), earthy and alkaline salts, are present in all of the higher forms; and the bases of these proximate principles existing in the supporting medium, whether earth, rock, or tree, their separation from it by organic action might be anticipated. Again, if we examine closely the attachment of many of the more minute, and even of the larger, crustaceous kinds (understand by this latter denomination, those which adhere like a crust to the substance on which they vegetate), we shall find that their under-sides are not superficially adherent only, but actually imbedded. This is the case with some which grow upon the hardest siliceous rocks and stones, and even on the glass of old windows; and it probably arises from the elaboration, during their growth, of oxalic and other vegetable acids, which, however weak and powerless in their action on such substances when mechanically applied, overcome the cohesion of their atoms during the slower process of organic assimilation. By whatever means, however, such an effect may be produced, its importance is the same; and the ministry of the lichen, commencing with the modification of the mineral elements of the fluid-water and viewless atmosphere, is succeeded by a corresponding action upon the solid crust of the earth.

The more conspicuous and complicated species of these plants, though they may often be observed covering spaces of considerable extent, to the apparent exclusion of all others, are, individually, only so many grades in the grand natural scheme of fertilization. In describing one of the most beautiful of the series, the *Stereocaulon paschale* of botanists, Sir James E. Smith, mentions having observed it coating the lavas of Vesuvius, which looked, at a distance, in many parts, as though they were covered with snow, owing to the abundance in which it vegetated there; but this species, chiefly, if not entirely, confined to volcanic and plutonic rocks, only appears upon them as the successor of many others, which have from time to time vegetated and decayed to form a soil fitted for its development; and the same may be affirmed of its equally or more distinguished brethren. Mere microscopic specks, like grains of impalpable powder, commence the mighty operation, solidify the air and moisture, soften and abrade the rock; broader and denser, and at length leaf-like, expansions follow in their turn, survive their time, and decay, until the deepening soil is prepared to receive the green moss, the grass, and the herb, and eventually becomes clothed with an exuberant vegetation. The course of changes under which the fertilization of a world has been produced has attracted the attention of an English poet, whom, as a correct observer of nature, a naturalist may venture to quote—

> "Seeds, to our eyes invisible, will find
> On the rude rock the bed that fits their kind.
> There in the rugged soil they safely dwell,
> Till showers and snows the subtle atoms swell,
> And spread the enduring foliage; then we trace
> The freckled flower upon the flinty base.
> These all increase, till in unnoted years
> The stony tower as grey with age appears:

With coats of vegetation thinly spread,
Coat above coat, the living on the dead;
These then dissolve to dust, and make a way
For bolder foliage, nursed by their decay.
The long-enduring ferns in time will all
Die, and depose their dust upon the wall;
Where the winged seed may rest, till many a flower
Shows Flora's triumph o'er the falling tower."

The lichens being the first purveyors of soil, it might be naturally supposed that these plants—whose invisible seeds seem to be ever at hand to fulfil their allotted function—would exist on all parts of the earth; and it is so. Their tissues are so little affected by the extremes of heat and cold, that the same apparent species is sometimes found occupying climates the most adverse, situations the most dissimilar in this respect; and regarding the order, or group, collectively, it may be stated as being distributed from the poles to the equator, and from the sea-level to the highest mountain summit, where certain species clothe the perpendicular rocks, amidst snows and glaciers, in the regions of ever-during frost. In these lofty alpine districts and lands, far beyond the Arctic circle, vegetation does not advance beyond the production of these obscure plants; but they are forming in such situations the basis of a soil which, under some future condition of our globe, may be hereafter destined to the support of vegetation of a higher cast. Thus circumstanced, they seem to constitute the first step between death and vitality; they have been called "the first heralds of life," but it is of a life which here commences and terminates with themselves.

The number of known species of lichen it is difficult to estimate with any approach to correctness, on account of the variations in aspect induced by difference of climate, exposure, and other circumstances. According to the enumeration of Fée, there exist between two and three thousand, but not more than half that number has been hitherto accurately examined and described; and of those which have been subjected to this ordeal, many are, doubtless, mere varieties of well-authenticated species in different stages of development.

Taken in the aggregate, the lichens present a structure and appearance too much diversified to admit of any general description devoid of the technicalities of botanical science, or, even if so encumbered, without illustrative figures. But we may take the green powder, already spoken of under the name of *Lepraria viridis*, as an example of one of the simplest forms of the tribe. An examination of the sides of a chalk-pit or open stone quarry will make us acquainted with a higher series, in the condition of minute black or coloured specks scattered over those parts which have remained for a few months undisturbed. A lens or magnifying-glass will be requisite to detect their organic character; but many of these are of beautiful and complicated structure, and in noticing them we have made, not one step, but over-strided many on the scale of vegetable creation. Patches, often circular in outline, of white, yellow, brown, or grey occurring on the walls of ancient buildings, rocks, stones, &c., lead us a few grades further. Some species, again, of thin leathery or papery consistence, overrun the ground in woods; others are clustered in bunches round the branches of trees, or hang from them like rags or hair; while several of equally varied aspect vegetate among the slender grasses and heaths on our moors, some branching like tufts of white coral, others spreading over the soil as a grey crust, and sending up numerous little greenish-grey stemmed cups or miniature goblets, bordered with studs of the most vivid crimson. Such are some of the more conspicuous members of the lichen family.

Highly valuable in the economy of nature, these plants are—like their aquatic parallels, the algæ—of comparatively small account in that of man. Consisting chiefly of a proximate principle allied to starch, they are generally more or less nutritive; a circumstance that, in cold climates, renders some of them useful articles of subsistence.

The species which has most attracted attention in this respect is the Iceland moss of our druggists—*Cetraria Islandica* of botanists—a plant that has long been a popular remedy in consumption and diseases of the chest. Though a native of North Britain, all that is used here is imported from Iceland and Norway. In Iceland, it is a common and much prized item in domestic economy, and is collected in large quantities for winter use as food; and the inhabitants of that barren and uncultivatable land, have a current expression that "the bounty of the Almighty gives them bread out of the very stones;" the lavas and volcanic stones on the western coasts of their island being covered with it. Previous to using they steep it in cold water, which extracts a bitter principle found in many of the lichens in their natural state; it is afterwards dried and reduced to a powder resembling meal or flour, which is either kneaded into cakes, or boiled with milk and eaten as porridge; in the latter state it is said to constitute one of the most wholesome and palatable articles of Icelandic diet. Some other species belonging to the genus *Gyrophora*, and growing abundantly on the rocks of Arctic America, are eaten by the hunters of Canada and of the Hudson's Bay Company, under scarcity of more nourishing food, being known among them by the name of rock-tripe or *Tripe de Roche*. Another lichen is the favourite food of the reindeer: this is the *Cladonia rangiferina*, or rein-deer moss; a species which, in Lapland and other high northern regions, attains the height of a foot or eighteen inches, and supplies the place of grass; covering the ground, according to Linnæus, over hundreds of miles in extent, and presenting to the eye of the traveller the appearance of a vast tract of snow during the summer.

Several of the lichens yield valuable dyes: of these archill or litmus, prepared from a maritime species *Roccella tinctoria*, and cudbear, obtained from *Lecanora tartarea*, a crustaceous kind, common on our mountains, are the principal.

A few species are said to be poisonous, but the repute is doubtful.

With few exceptions our hardy vegetable pioneers are left undisturbed by their fellow-beings of the animal kingdom, from the insect to the man, that the work so essential to the welfare of every grade of existence may be fulfilled without stint or measure; and wise indeed has been that dispensation under which their earliest and most important functions are concealed from human eye, and placed beyond the control of human judgment, allied as are all its actions with human caprice and blindness to future results.

THE NEW POWER, AND ITS FURTHER APPLICATION TO AGRICULTURAL PURPOSES.

In drawing attention to the plough, we have purposely avoided referring to a defect, which, according to many, is productive of the greatest practical evil in working—we allude to the padding or poaching of the soil by the horses' feet. Although it is necessarily an evil always attendant upon the plough, it is but right to admit that it is one which is shared in by all cultivating implements, rotary or otherwise, which are dragged, or proposed to be dragged over the land by the power of horses. It is an evil attendant upon the mode of working the plough, but has no direct reference to the plough itself; it is simply a necessity of the mode of working it. It is obvious that this evil can only be got rid of by the introduction of a new power, which shall be able to drag the implement, of whatever kind employed, on and through the soil, without in any degree interfering with the state of its surface, that the soil which the implement has to contend with shall be its natural state; and that the very means employed to work it shall *not*, as in the

case of the horse with its poaching feet, bring about a state or condition which shall require the implement in some measure to do away with this if it be possible. Everything around us tells us that this new power must be steam. We have bound this power to be our willing slave, with its might that can shatter an oak, yet be controlled by an infant's hand; and have set it to whirl the wheel, drag the car, and propel the ship; and shall we, in view of the giant aid it affords us in those things, doubt of its capacity to till the soil and reap its products for us?

But in endeavouring to avail ourselves of a new power, it is of the utmost importance that we should consider how, and in what manner, we can most economically make use of it. It by no means follows that we do all, if we simply try to adapt the new power to an old and established implement or system of culture. On the contrary, sound philosophy no less than common business prudence, leads us to consider whether a new implement or a new mode of culture will not probably be required before we can take advantage of the capabilities of a new power. If we look at what has been done in manufacturing machinery—and the best amongst us need fear no shame, or will incur no charge of inefficiency, by taking a lesson from our brother mechanicians who dwell amongst the "cotton men"—we find that this principle is almost invariably acted upon: new machines with new processes, on the adaptation of a new power. It would be as easy as we hope it is unnecessary to cite numerous exemplifications of the truth of this. There is, indeed, everything to induce our agricultural mechanics, on the one hand, to think well as to the best means of availing themselves of the capabilities of this new power by the adoption of a new implement; and our agriculturists, on the other, on the introduction of a new method of *preparing* land for the operation of this new implement; but of this latter consideration more hereafter. There is no such degree of perfection in the work performed by the plough, or such economy in the doing of it, as to induce a belief that our successors will be as much wedded to it as we are ourselves; on the contrary, we have shown that it possesses defects acknowledged by all; and that these, in place of being overcome, may be aggravated by the application of a steady power like that of steam. If the plough is to be retained with steam as the traction power, those defects must be overcome if we wish to attain economy in the working power as well as efficiency in the work performed. But even granting that with these defects overcome, the work performed shall satisfy the cultural requirements of the question, there are many who think that sound mechanical reasoning inevitably leads to the conclusion, that a machine on a principle distinct in its operation from that of the plough will be required, to satisfy at once mechanical as well as its cultural requirements. Modifications of its mechanism may make the plough do good work; it is questionable whether steam-power will enable it to do as cheap work as would be done by steam working an implement expressly designed to aid its peculiarities. There are at all events many reasons for supposing that the plough is not adapted to the new power; hence before much further outlay is made in the direction of applying the new power to the old implement, it will be as well to consider in *all* its bearings the important question. In what direction must efforts be made to avail ourselves of the power of steam for the cultivation of our lands? Too much stress cannot be laid upon the injunction—common-place enough, doubtless, but too often lost sight of, probably from being so very common-place—that the direction in which we are to go must be decided on before any true progress can be made. He would be deemed but a poor navigator who set out from one port to reach another, without providing himself with charts, or information as to the shortest way of reaching his proposed destination. It is not to be wondered at, therefore, that not a few amongst us look upon all plans for steam-*ploughing*, and for substituting the direct traction of a locomotive for that of the horse, as movements by no means in a philosophical direction, although gladly enough admitting their value as transition plans, tending gradually to an appreciation of the capabilities of the new power; forcing our train of thought out of the grooves in which it ordinarily runs, and showing to thinking minds what might be done, not so much from what those plans do, as from what they cannot do.

Leaving then the question as to what the mechanic has to do to bring about the application of steam-power to the culture of land in this transition state, to which the discussions and projects of the last few years have brought it, we proceed to proffer a few remarks on what must, we think, be the duty of the agriculturist in aiding the mechanic in his important task.

If it is true that in certain branches of our manufactures the adaptation of a new power necessitates the invention of new machines, it is not the less true that these new machines necessitate on the other hand increased care in the preparation of the material on which they have to operate; hence we find processes of preparation as well as realization or finishing. It is, we believe, an axiom in mechanical operations, that to make the application of steam power pay for the outlay and the cost of maintaining it in operation, this operation must be continuous. If the process which it is designed to aid be subjected to a series of annoying stoppages through any internal fault in the construction of the machine which carries it on, or through the bad state of the material on which it operates, then a continual drain on the capabilities of the working power is kept up, and much of the advantages lost which render it, in cases where it is working under fair circumstances, so superior to manual or animal labour. There must be a mutual adaptation of material and machinery; the machine must be fitted to work the material into the final condition which is desiderated, and the material must not present any peculiarities which will prevent the machine giving its best and its quickest work. It is not giving a machine a fair trial to bring it to do work under circumstances presenting obstacles which it was never designed to overcome. And yet this is what has been done by many of our farmers. They have asked our mechanists to invent machines; and when they have been brought out, designed to do work under certain circumstances, they have failed because these circumstances have not existed, and have been blamed for a fault which did not originate with their designers. The manufacturer, in asking a mechanic to devise a machine, informs him of the process through which the material is to be put, and the mechanic adapts his mechanism accordingly; but it is on the understanding that the material is prepared to suit its action; and this preparation of material is effected by machinery or processes possibly as expensive in their first construction and operation as those destined for the finishing of the article; and yet he who grudged these processes of preparation would be laughed at; they form part of the manufacture, and can be no more left out than the part of the Dane in the play of "Hamlet." It will be seen then to what conclusion we are evidently drifting. If the mechanic has his part to do in the invention of a machine or implement to till the land under very different circumstances from those existing under the old system, the agriculturist

has no less his duty to attend to, in the preparation of the land, so as to aid to the utmost the adaptation of this new power, and the working of the new implement. There is a position held by many now, namely, that culture of the soil by the power of steam, whether this be effected by the plough or by any other machine or implement, must be a process subsequent to another or others, this or those having for its or their object the preparation of the land so as to aid the cultural operation. If the fields are cramped in dimensions by hedge-rows or ditches, the one must be remorselessly pulled down, the other unhesitatingly filled up; if hillocks or hollows impede the progress of the machine, the redundancy of the one must be cut down to afford material to fill up the vacancy of the other; if huge boulders threaten to stop, or, if not to stop, to damage or injure the mechanism of the implement, these, at whatever cost of time and trouble, must be exterminated. Every obstacle, in short, must be removed, which can tend to impede, and every facility be granted which can tend to aid the progress of the steam-worked cultural implement. We do not say that it will pay to do all this; this is obviously another consideration which belongs to the province of the farmer himself; but taking simply and solely the mechanical view of the question, there can be little doubt that if the steam-dragged plough, or the steam-impelled cultivator, be expected to do all the work of which it is undoubtedly capable, this previous preparation of the land must be gone into. There can be no doubt of the truth of this position, whatever doubt there may be as to the paying capabilities of this thorough system of operation. Half work may pay better than whole; but if whole work, which—to be truthful—is the only real work, is ultimately judged the most expedient to be carried out in the cultivation of land, the whole preparation must also be made. The locomotive without the rails would not attain the lightning speed it does, and the rails would be an expensive investment if horse traction was to be used; the line and the locomotive both, are required to perfect the railway system. So in steam cultivation: there must be a mutual adaptation of the power to the material, and *vice versâ*. In stating these views, we but echo the opinions of many gifted and far-seeing agriculturists and mechanicians; and we are glad to avail ourselves of the opportunity here presented to us, by giving, as closely relating to the point, the opinion of Mr. William Fairbairn, one of the most eminent of our engineers; the remarks were made with special reference to reaping machines; but they have, as will be seen, a close bearing upon the question which has occupied our attention. "There is, however, another element equally important and essential to the efficiency of the process of reaping, and that is the *preparation of the land;* and, in fact, before we can look forward to ultimate success, the surface must be levelled, and the present injurious system of ridges dispensed with. To a casual observer it is obvious that our present state of culture, as pursued in most parts of Europe, is not calculated to afford the necessary facilities for ensuring a successful progression into machinery. To supply machines successfully to the labours of a farm, the land must be prepared, not for hand, but machine labour; and the successful introduction of reaping machines will chiefly depend upon the preparations that are made for their reception. The system of ridges may be tolerated and overcome by the sickle; but to give to the new process of reaping by machinery its full effect, a totally different plan of operations must be pursued, and the fields laid down with a perfectly smooth surface. The larger description of stones and other obstructions should be removed, and in place of the superfluous water not required for the nourishment of the plants being allowed to flow between the ridges on the surface of the field, sweeping in heavy streams, as it now does, everything before it, the new system of drainage will require to be adopted, and the water carried under in place of running over the surface.

To make a machine, such as a reaping machine, work well, everything must not be left to the machine; the agriculturist must do his duty as well as the engineer; and that duty once performed on both sides, a certainty of action will be secured, which will solve the problem, and effect satisfactory results. Having arrived at these happy results, we may then, *and not till then*, reasonably look forward to the crops being well and quickly gathered by machinery, to the exclusion of a laborious process, effected with difficulty and often imperfectly by the human hand."

AIR: HOW INVALUABLE TO THE SUCCESSFUL HUSBANDRY OF THE SOIL AND ITS PRODUCE, ANIMAL AND VEGETABLE.

In our former observations on this subject we directed attention to a general view of it, promising to notice on a subsequent occasion the individual case of soils, plants, and animals, under the different atmospheric circumstances in which they are found. We now propose fulfilling that promise.

In doing so, let us examine wheat, grass, and turnips, grown in different soils, climates, and under different systems of cultivation.

Under the first, as to soil, the practical question at issue may be thus stated, How far does the atmosphere affect the quality of wheat on any individual soil? That the nature of the soil and its atmosphere influences the composition of both the grain and straw of this cereal, is a fact with which farmers have been familiar from time immemorial. To what extent, therefore, is this dependent upon atmospheric phenomena? Calcareous soils, for example, and others abounding in organic substances, yield wheat containing a larger proportion of gluten or nitrogenous matter, than do soils of an opposite quality. How much of this nitrogen is due to the nitrogen of the atmosphere, and how much to that of the manure incorporated with them?

In the case of a calcareous soil, the decomposition of lime by means of air and water obviously works up the oxygen of both the latter, liberating their nitrogen and hydrogen; while they, uniting together under favourable circumstances, form ammonia (N 1 + H 3). In this manner 82.545 lbs. of nitrogen, and 17.455 of hydrogen would make 100 lbs. of ammonia, requiring the decomposition of 107.2 lbs. of common air and 167 lbs. of water. Now, as this quantity of ammonia is a sufficient dose for two acres of land, yielding an ordinary crop of wheat, it will readily be seen that the decomposition of this quantity of air and water over such an area, the liberation of this quantity of nitrogen and hydrogen, and their uniting together, is the most likely source from whence the growing wheat plant derives a large portion of its nitrogen.

Pure ammonia, however, cannot thus be formed in a

calcareous soil, as it always combines with other substances; but this does not in the slightest degree affect the question at issue, for it signifies little what salt of ammonia may be formed, so long as it is formed and consumed by the plant.

In soils, again, rich in animal and vegetable matter, a similar result takes place during the process of decomposition. As in the case of calcareous matter, air and water are necessary to effect this change, during which the oxygen of both produces, with the vegetable matter, carbonic, ulmic, and other acids, while the nitrogen and hydrogen liberated form ammonia.

If, however, we suppose such a vegetable soil improperly drained, so that decomposition takes place in the absence of air, or a sufficient supply of it, then the vegetable matter and oxygen form the carbonic and other acids; but the hydrogen now unites with the carbon, forming carburetted hydrogen, or the gas of low-lying marshy lands—a gas alike injurious to animal and vegetable life.

Wet marshy soils of this class are, perhaps, the worst for wheat culture of any, being deficient of ammonia to supply nitrogen for the manufacture of gluten. For the successful growth of this cereal, proper drainage and aëration are essential requisites. A certain degree of moisture is, no doubt, necessary to supply hydrogen; but in our moist climate, few crops require so little rain as wheat, while none require a larger supply of atmosphere, beans and peas excepted.

On sandstone and clay soils, naturally deficient of organic matter, and where the inorganic is less subject to decomposition, on the contrary, wheat seldom yields very abundantly, while the quality of the flour is inferior, owing to the small per-centage of gluten which it contains.

This deficiency of crop, and the inferiority of quality, are thus accounted for: In the first place, the inorganic matter being less subject to the action of oxygen than limestone, the decomposition of air and water is consequently also less, so that the supply of naturally manufactured food, both organic and inorganic, is insufficient to supply the wants of a healthy and luxuriant vegetation. And in the second place, the decomposition of air and water being less, the manufacture of ammonia is also less, and, hence, the formation of gluten.

In the case of grass crops again, results are similar, the produce of dry calcareous or vegetable soils being better for rearing and fattening stock, than that of others of a different quality not so subject to the decomposing influence of the atmosphere. We might quote many examples from the rich grazing districts of England and Ireland, in proof of this proposition, were it necessary.

In low-lying, marshy grass-lands, however, the example is widely different from that of wheat-land, in more respects than one. In the first, for example, luxuriant crops of an inferior quality are often produced by this class of soils; and although not equal to straw as food for cattle, they make nevertheless excellent manure. As such we have used immense quantities, both in a green state and dry, for littering stock, and always had fine crops.

For pasturage they are not well adapted; the marshy gases arising contaminating the atmosphere, and thus injuring the respiratory functions of stock, or otherwise affecting their health. In corroboration of this, we shall mention two examples: In the first, large tubercular swellings break out, principally about the neck and chest of cattle, the malady generally terminating fatally. And not only are they affected thus when grazing, but also when consuming in the straw-yard, alike in summer as winter, the produce of such lands, as turnips, hay, and straw. In the second example, cattle never thrive well; while they change their colour, whatever it may be, to a "dirty dun."

Some low-lying wet grass-lands, we must observe, are exceptions from the above examples, the produce being rich in quality and abundant in quantity. This is owing to the water not being stagnant, but rising to the roots of plants by capillary action, and bringing a sufficiency of lime, alkaline, and other salts, in solution, to counteract acidity and supply the necessary quality of food which otherwise would be wanting. The grass, however, owing to the decomposition of air being less (and consequently the produce of naturally-formed ammonia), is generally deficient of nitrogenous element, and therefore is better adapted for yielding butter than cheese or butcher-meat; but in practice this deficiency is easily supplied by the addition of a little pea or bean-meal and cake.

Like grass, the turnip delights in a rich, well-drained, calcareous soil, or one full of vegetable matter, with a moist climate, both top and bottom having a liberal supply of air. An abundance of pure air is essential for the growth of this invaluable plant; for without plenty of room, a well-pulverized soil, and an atmosphere free from deleterious matter, a heavy crop cannot be grown. At the same time more water appears to be assimilated in the process of vegetation than nitrogen from the atmosphere; thus proving that as the turnip is a large consumer of ammonia—a great decomposer of air and water—nitrogen-gas must be given off from its leaves.

With regard to climate, it is much more diversified than is generally imagined. In common conversation we talk of the north, south, east, and west, as cardinal distinctions; but when we come to examine the details of even a single province, let it be situate where it may, how different is the atmospheric circumstances of one farm from that of another! and how unlike are the results on animal and vegetable life!

Such diversities are to be attributed no less to geological than geographical causes. When we enter the field, may it not be said, How little is yet known of the "chemistry of common life!" for here the undivided labours of the farmer are directed to one continued process of decomposition! as if man had but one grand object in view—viz., to pull down as fast as Nature builds up the animal and vegetable kingdoms! Nor are results to be measured by his own individual efforts; for mechanical appliances without number are now being brought to bear upon the soil, exposing it more effectually to the decomposing influence of the atmosphere, in order to increase both produce and consumption.

This decomposition of the soil and its produce must affect the contiguous atmosphere less or more, and hence the quality of the crop. The smell of newly-ploughed land is sensibly felt, for instance, on entering the field, and from different qualities of soil it is equally different. From time immemorial, ploughmen have experienced certain localities more healthy than others; and the difference is obviously to be attributed to climate, as affected by the volatile matter given off in the process of decomposition.

We might here enter into a large amount of detail, quoting examples from different geological formations, did our limits permit; but this blank we shall leave our readers to fill up themselves. If they take up a clod and break it, they may easily detect what the smell or volatile matter given off into the atmosphere is composed of. Or if they can analyze it, they may also be able to say what will be liberated in the process of decomposition. All that we shall add is this—Were every farmer in possession of the analyses of the different qualities of soil he cultivates, and volatile matter given off in the process of decomposition, it would prove an interesting source of information to him; and when a few sovereigns would obtain it, why should it not be had?

The atmosphere, again, is sensibly affected by different crops, and that differently at different stages of

their growth. Who has not felt, for example, the intoxicating aroma of peas, beans, and clover in flower?—the fragrance of the meadow during hay-making?—the pungent smell of turnips when growing rapidly?—and that of a field of barley behind the reapers or reaping machine in harvest? These, although prominent examples, are only a few of what experience is familiar with, and which might readily be quoted for the sake of illustration.

Our next topic is cultivation. How does it affect the influence of the atmosphere upon the soil and its produce?

With regard to the soil, it is only when accompanied with a sufficiency of moisture that the atmosphere can enrich it. If divested of water, the scorching effects of a summer's sun would render our fields as barren as the deserts of Arabia; but with the requisite supply of this invaluable fertilizer, the rays of the sun are powerful auxiliaries to the enriching of them. To "keep in the sap" and "out the drought," and yet admit the free circulation of the atmosphere, has long been acknowledged one of the cardinal points in good farming.

Deep culture and drainage, again, by increasing the capacity of the soil for holding air, add greatly to the means of enriching it. Probably more of the success of the Lois-Weedon system depends upon this, than to the mere fallowing of the "intervals" between the beds of wheat or other kinds of crop; so that the question may yet be raised whether equally deep culture, with proper attention to seeding the ground uniformly, may not produce equally beneficial results. But be this as it may, the chemical effect of air and water in a greater depth of soil is manifest from what has already been said; for the decomposition of the soil, air, and water (and hence the formation of soluble matter and ammonia) will be directly as this depth—twice the depth of ordinary cultivation by the plough producing twice the quantity of fertilizing matter, while from the greater depth there will be less escape or waste of volatile substances.

The free circulation of air, again, access of light, and rays of the sun, among growing crops, are questions of equal importance. In this respect wide drilling is highly advantageous, while intervals may produce a more healthy and free circulation. But much of this will depend upon special circumstances; for clean flinty straw on the wide-drill system may admit of a freer circulation than coarse flaggy straw deficient of silica with wide intervals.

Many exceptions may no doubt be taken to the wholesale manufacture of ammonia, as advocated, from the nitrogen set free in the decomposition of air, uniting with the hydrogen of water when undergoing a similar process; but granting them to be true, the practical question in the field is obviously to reduce exceptions of this kind to the common rule. This may be done in various ways—as by draining; deepening the soil; adding clay, calcareous, and vegetable matter to sandy lands, to retain moisture and produce decomposition; sand, vegetable, and calcareous matter to clay lands, to promote the free circulation of the atmosphere, and its decomposition along with that of water; in short, anything which will promote the decomposition of air and water in the soil, so that the nitrogen and hydrogen set free shall be united so as to form ammonia. We see no other way of accounting for the extraordinary fertility produced by improvements of the above kind, than by working up the nitrogen and hydrogen set free in the process of decomposition into ammonia, or some of its compounds, as food for plants. The decomposition of farmyard manure in the soil, and even clean straw in clay lands, obviously works up the nitrogen of the atmosphere and hydrogen of water into matter more fertilizing than their own constituent elements will satisfactorily account for. The advocates of exclusive liquid manuring overlook the economy of decomposing vegetable matter in the soil, and the additional supply of ammonia derived from this source by means of the nitrogen and hydrogen liberated in the process.

THE GRADUAL IMPROVEMENT IN THE THRASHING MACHINE.

"Portable thrashing machines," wrote Loudon twenty-five years ago, "are very common in Suffolk; it being not unusual for an industrious labourer, who may have saved thirty or forty pounds, to own one worked by three or four horses. Reaping-machines and steam ploughing-machines will probably in a few years be owned and let out for hire in a similar manner." After more than "a few years," reapers and steam-ploughs have not yet attained a similar position with itinerant thrashing-machines, although rapidly coming into extensive adoption by large farmers. However, thrashing-machines themselves have taken a form that our author never anticipated: the portable steam-engine, and that marvellously compact piece of mechanism, the combined thrashing, shaking, winnowing, and finishing-dressing "drum," "barn-works" or "mill," having completely raised the character of agricultural machinery, and as a necessary consequence multiplied mechanical knowledge among farmers and their workmen. Directly it was proved that steam power could be advantageously conveyed from farm to farm, not only a higher velocity of the drum, and a greater amount of work in a given time was achieved, but the operations of straw-shaking and winnowing, previously confined almost entirely to thrashing machinery erected in buildings, were now added to the portable machines. As far as mere knocking out of the grain is concerned, we have now comparatively little to wish for, and may expect only slight improvements in augmenting the quantity done, economising the motive-power, avoiding splitting, and accommodating the beaters and concave to all conditions of "stuff." In the apparatus for separating the corn, chaff, and straw, considerable advances may yet be made; and as next July will try what our inventors and manufacturers can do for us in this department, it may be well for farmers to devote some consideration to it beforehand.

One of the earliest ideas in connexion with thrashing by machinery was that the separation of corn, chaff, and straw, should be effected, as well as mere shelling out the grain from the ear. Thus Michael Sterling, more than a hundred years ago, applied the principle of flax-hulling to beat out corn, in a machine consisting of a vertical shaft carrying arms or blades revolving in a cylinder—the corn being fed in at top, and the straw and grain separated by riddles and fanners underneath. This was thirty years before the invention of the drum and beaters by Meikle. In 1789, three years after Meikle's first machine was constructed, with a drum of four scutch-beaters and a pair of feed-rollers, the first machine having a circular rake attached for shaking the straw, and fanners below for cleansing the grain, was erected in Northumberland. In 1795, Wigfull, of Lynn, in Norfolk, patented a machine in which the corn falling from the drum was

carried by means of a shaking screen and rolling-cloth or endless web to the blast of a fan, where it was separated from the chaff. Of course our space will not permit us to chronicle here all the successive improvements in thrashing machinery; but these instances show how ancient is the addition of shaker, riddle, and fan, which we are still labouring to improve. The straw-shakers of the old Scotch machines are generally known as being large drums, armed with rakes, revolving above fixed curved racks or screens, over which they pass the straw; some machines having one of these drums "overshot," and furnished with brushes as well as rakes or forks. The separating apparatus consisted of a couple of winnowing-machines underneath, similar to those made for hand-power, catching the grain and chaff from the drum and shakers by means of a large deep hopper.

The parallel-motion shaker, so much in favour now, appears to have been invented in 1840, by Mr. Morton, of Whitfield Example-farm, and erected as part of the steam-thrashing machinery there by Mr. Clyburn, of Uley Works. It consisted of parallel spars of wood, 6 feet long, and three-quarters of an inch thick, with three-quarter inch spaces between them; these being joined together in two alternating sets, were jumped by double cranks on two revolving shafts, as our present box-shakers are. This was about the first time that straw was subjected to a real "shaking." Other parts of this machinery were equally ingenious. The corn fell before the blast of a fanner, then down before another; the light grain and short straws thrown out by this first winnowing being taken up by an "elevator" again to the feeding-board of the drum. The winnowed corn was carried up by other elevators to another winnower, or rather two, one under the other, with two fans, and was finally again elevated to the sacks, or passed through a "barley-hummeller." An endless web was tied at the mouth of the drum, to carry the unthrashed straw gradually to the beaters. Since that time, this web has been abandoned; another first winnower has been added, fed by an endless web beneath the drum and shaker; and the corn after falling before the first blast is sifted sideways into the hopper of the two lower dressing-machines; and a horizontal cylindrical sieve or "separator" was also applied. The idea of adapting winnowing apparatus to *portable* thrashing-machines, carried into effect by the Lynn machine-maker, in 1795, was revived just half a century afterwards. Earl Ducie exhibited at the Southampton Meeting, in 1844, a "recent and scarcely completed machine," the invention of Messrs. G. Parsons and R. Clyburn, which Mr. Miles reported as being "truly original." At Shrewsbury, in 1845, this machine was driven by Dean of Birmingham's portable engine, itself a great novelty, and awarded a prize of £10. It thrashed, cleaned, and finally sacked the grain; and Mr. Parkes in his report said, "It is a powerful machine, and possibly adapted to the very large rather than to the moderate-sized farm." In 1846, at Newcastle, a thrashing-machine was exhibited by Cambridge, having a reciprocating rake attached, for the purpose of collecting and passing the straw from the drum without harbouring the grain; and the lower part of the machine was inclosed so as to form a box or receptacle for the grain to fall into. But up to a year later than this period we find that improved horse-power machines without dressing apparatus occupied the most prominent place in the catalogues of the great makers; while hand-power thrashing machines were much in request as novelties. At Northampton, in 1847, Hornsby showed a thrashing-machine with a revolving shaker; Cambridge one also with, a shaking apparatus attached; and J. Cornes, jun., of Market Drayton, a thrasher with straw-shaker and elevator, the shaker six feet long; Hayes, of Elton, had a straw-shaker; and Clyburn exhibited a horizontal cylindrcal "separator." Ryland and Dean, of Birmingham, however, showed a complete machine for thrashing, winnowing, and bagging the grain. At York, in 1848, Hornsby had his improvement of Clyburn's shaker; Summers, of Wold Newton, a rotary straw-shaker; Scott, of Belfast, a revolving-rake shaker; Humphries, of Pershore, a thrasher with winnowing appraatus and shaker; Garrett, a thrasher with straw-shaker and jogging screen for separating the colder and refuse from the grain; while Abbey, of Dunnington, exhibited a horse-power thrashing-machine with blowing-case, riddles, and elevators which filled the sacks with corn; and Burrell, of Thetford, gained a silver medal for his portable thrashing and dressing machine with parallel-bar shaker, invented by W. Palmer, of Southacre, capable of thrashing five or six quarters per hour, and delivering the corn, chaff, straw, and siftings or short straws in separate places. The price was only £75, yet the machine was at that time supposed to be very cumbrous for ordinary farm use. At Norwich, the next year, Clayton and Shuttleworth produced their box-shaker, three feet wide, and fourteen feet long; Crosskill, also had a shaker, "on a new principle"; Hornsby showed a double-cranked or jumping straw-shaker; and Sargison, of Wisbeach, a shaker having sieves or riddles of perforated galvanized-iron, which propelled the straw and pulse forward, while the grain sifted through. In addition to Burrell's thrashing and dressing machine, Cambridge showed one invented by Humphries, for thrashing, winnowing, and weighing; Holmes, of Norwich, a horse-power machine with a newly-invented jog colder riddle, and a new straw-shaker; Garrett, a thrasher with chaffing apparatus; and Ferrabee, of Stroud, a machine with double-crank shaker, and an endless band for delivering the corn and chaff to and elevator which carried it to an ordinary winnowing-machine. And it is noticeable that the manufacturers felt it necessary to call attention to the fact that their portable machines for doing all this work at once did not require to be removed from the carriage-wheels on which they were mounted. In the *Farmer's Almanac* for 1850 appeared the first engraving of a portable combined thrashing-machine, viz., Garrett's; the shaker consisting of spars with spikes rotating upon cranks at the inner end and vibrating on rocking-bars at the other. About the same time came out Clayton and Shuttleworth's portable combined machine; the shaker-boxes having a parallel motion, by means of wheels and spindles connecting the crank-shafts, instead of connecting-rod and cranks as before; and there was a vibrating trough extending the whole length of the machine. Tuxford's table shaker-off was also introduced; at first having a rotary jumping movement by means of mitre-wheels and a spindle connecting two crank-shafts underneath, instead of hanging on slings as at present.

It is only six or seven years, therefore, since we obtained the portable thrashing-machine in its present form; that is the vital parts which are now being improved and altered (but still generally adhered to) in every possible form. We may mention as one of the greatest and most extensively-adopted improvements, Humphries' divided and reciprocating trough or shoe; and as variations from the common form, Ransome's revolving Brinsmead shaker, and Hornsby's worm or screw for feeding the riddles.

THE INCRUSTATION OF CEREAL AND OTHER SEEDS.

By F. R. de la Trehonnais

I.

Formerly, when science was still in its infancy, experience to a certain extent, but routine especially, were the only guides of agriculturists in their modes of preparing the ground for the reception of the seed. Farmyard manures and bare fallows were the only means of restoring the spent energies of the soil; and these were then, and are even now to a great extent, indiscriminately resorted to, without any regard to the chemical constitution of the soil, or the requirements of the plants that are to grow upon it. Analytic science, and the wonderful discoveries of vegetable physiology, have of late years thrown a great deal of light upon the subject of manure, its mode of application to the soil, and its assimilation by the plants. And yet, practically, little progress has been made. We have superphosphate, it is true: we see a great many kinds of artificial manures daily advertised in our agricultural papers; but, after all, the progress we have accomplished is by no means adequate to the strides which science has made in the analytic knowledge of manures, in the exact appreciation of their fertilizing qualities, and their action upon vegetation in various plants. We still cart away to our fields the same ponderous loads of farm-yard dung, a large percentage of which is of no earthly use, and can only be regarded as the huge vehicle of a very minute proportion of ammonia and alkaline salts. Even guano and superphosphate of lime are encumbered with a large proportion of useless ingredients, all of which are costly to purchase and cumbersome, and therefore expensive to carry. Besides, what a large proportion of the manure which we lay over our fields is utterly lost to the crop we want to grow! what a large per-centage is eaten up by noxious weeds, or disseminated through a part of the soil untouched by the ramifications of the roots, and therefore immediately useless! On the other hand, we know, from clear demonstration, what the substances are which each kind of crops draws from the soil; we know to a fraction the quantity of each of those substances respectively; and when we come to compare their aggregate weight at per acre, with the quantity of manure which we have laid over that extent of ground, we are astounded at the difference in bulk and weight.

II.

If a plant is dried and burnt, the little pinch of ashes that remains, after complete combustion, represents the amount of mineral substances which the plant has drawn from the soil. The rest, which has evaporated in the air by the process of combustion, represents those constituent parts which the plant has derived from the air. Chemistry tells us exactly what substances the ashes contain, and in what proportionate quantities. It is then obvious, that either the soil or the manures put on it, or, as is more generally the case, both combined, have supplied those substances to the plant, without which it could not have arrived at maturity. But here we may well pause, and ask ourselves whether, in order to administer to the plant so small a quantity of matters—another and a more simple mode cannot be found; for that quantity, though it be multiplied by the number of plants in an acre of ground, still remains comparatively minute in the extreme, when we compare it with the bulk and weight of the 20 or 25 cubic yards of dung we have laid over it, besides the pulverulent artificial manure or guano we have drilled with our seed. Again, if we calculate the cost of that manure and the value of the labour which its use has necessitated, we find that the little heap of ashes which has been the result, has cost us an immense sum of money; in fact, a much higher sum than the pure chemicals of which it consists could be bought for in the trade.

III.

Hence, the general tendency of efforts on the part of both scientific men and practical agriculturists towards concentrated manures, that is, diminishing the bulk of useless substances, serving merely as vehicles to the really fertilizing element, in order to render them more portable, and more energetic, proportionately with their bulk. Abstractedly, this is evidently the goal of our progressive ideas in agriculture; that is, the simplification of all the means, either in labour or manures—the one by concentration of fertilizing energies; the other by means of ingenious machinery, and especially the use of steam-power in field as well as barn operations. It is true to a certain extent that, apart from the primary purpose of restoring the exhausted fertility of the soil, stable and other bulky manure have other advantages, mechanical and thermal; for instance, in dividing a stiff soil, and imparting to it a higher temperature by decomposition from fermentation. But, with thorough drainage, these advantages have become less depending from the action of stable manure; and I have no doubt but, as we progress with time, the corn-growing farmer will no longer be obliged to have recourse to the present troublesome and expensive mode of manufacturing his manure. A more definite delineation will divide the operations of the corn-growing from those of the breeding and grazing agriculturists, by which the pursuits of the farmer will become less complicated, demanding a smaller capital, diminishing his risks, and materially adding to his gain. Every farmer in England knows well that the lean stock he is obliged to feed on his farm brings him no immediate profit; and, were it not for the manure, he would incur a positive loss—setting for nothing the labour, anxiety, risks of mortality, and the locking up of capital, which the feeding of lean stock entails.

IV.

From the foregoing preliminary observations, we are naturally led to ask the question, How are these disadvantages to be removed? How are we to turn scientific discoveries to a practical account? How are we to concentrate our manures, and simplify their fertilizing constituents, so as to reduce them to the bulk of the amount actually assimilated by the crop; and, having succeeded in this, how are we to apply them?

A few weeks ago I communicated to this paper the translation of a very remarkable memoir upon the nutrition of plants, by the celebrated Boussingault, describing a series of experiments which clearly demonstrated the possibility of enabling a plant to accomplish all the phases of its existence, viz., its germination, normal growth, bloom, fructification, and maturity, in pure calcined sand, in which were introduced pure phosphate of lime, vegetable ashes, and nitrate of potash, which contain the mineral constituents of the plant selected for the experiment — *Helianthus argophyllus*. Here, it is very obvious that the soil was essentially used only as a

vehicle to the plant wherein it might strike its roots, and also to the ingredients which were added as food for its development and maturity. So it matters not how destitute of every nutritive element a soil may be, if it do not contain any substance noxious to vegetation—provided it can be supplied with the constituents of the plant which is to grow from it. If those constituents may be so placed in close proximity to the roots that they may be all absorbed by the plant in the course of its development, there is no necessity of placing in the soil a larger quantity than will be assimilated by the plant. In other words, if the analysis of the ashes of the plant shows that it has absorbed, say ten grains of the various elements added to the soil, and, in respective quantities, if it were possible to introduce those substance in so close a proximity to the roots that the whole might be integrally assimilated, there is no doubt but the mere addition of exactly ten grains of the mixture, in the same proportion as found in the ashes, would be quite sufficient to insure the normal development of the plant.

It must be admitted, however abstract the foregoing proposition may be, that if the principle it propounds could be practically applied, it would be the very limit to which progress can attain; and as I have already remarked, it is impossible not to perceive that it is to that concentration and simplification of means that we are now directing all the efforts of our skill, knowledge, and ingenuity.

Boussingault, in his recent experiments in the production of what he calls a *limit* plant, has proved that the seeds of many plants contain the necessary quantity of nitrogen, not only for the germination of the plant and the nutrition of the nascent stem and leaves before the radicles have been sufficiently developed to draw a supply from the soil, but also to the production of a perfectly organized plant, though exceedingly reduced in its dimensions. In fact, such a plant—after several months' existence in the open air, or even in a confined atmosphere—has been found to weigh but very little more than the seed from which it sprang. This clearly shows that the extent of the organism of that plant was limited by the quantity of the nitrogenous principles contained in the seed; but as soon as he applied to the soil (exclusively composed of calcined quartz sand, not containing a particle of decomposed matter or mineral manure) a small quantity of phosphate of lime, nitrate of potash, and vegetable ashes rich in silicate of potash, the plant immediately sprang up from its torpor, and grew luxuriant and strong, bloomed, and brought forth matured seed as well and as rapidly as another plant of the same kind had done upon a garden-strip richly manured.

This experiment clearly shows that the soil upon which the plant grew exercised no immediate influence whatever upon the growth of the plant, as far as its nutrition went, but merely as a vehicle for heat and moisture, as well as the holder of the plant and of the pure mineral salts upon which it lived and developed itself. This naturally leads us to ask the question, whether, instead of incurring great expense and trouble in manuring the soil thoroughly with heaps of dung containing but a small percentage of fertilizing matter, which is still reduced and less available to the plant by being disseminated over a larger surface than the roots of the plant can possibly compass, it be not possible to manure the seed itself, that is, surround it by a crust formed of the very mineral substances which are necessary to its growth, in the same proportion as they are found to exist in the seed, and in a sufficient quantity to represent exactly the weight of the aggregate mineral substances which are abstracted from the soil by the well-matured normal plant? This crust could then be considered as the mere extension of the seed to a larger bulk; and as the seed contains what is necessary to feed germination, and even to form a complete plant, though limited in weight to the extent of food contained in the seed, so the seed being increased to any required number of times its size and weight by the agglomeration of substances, such as phosphates, nitrates, and silicates, would be enabled to supply to the growing plant the necessary elements of normal growth and perfect maturity.

VI.

This is indeed no new theory, and many have been the attempts even in times of remote antiquity to realize it in a practical manner. Many are the inventors of wonderful liquids, in which the seeds were to be steeped, and thereby imbibe all the required elements of nutrition and fertility. All these have failed, not because the principle was not a sound one, but because it was not properly applied. For it is obvious that a liquid manure, however rich in fertilizing elements, could not fix these round the seed in a sufficient quantity so as to increase its store of nutritive matters—this can only be done in a solid form. Then, until very recently there was also the insuperable difficulty arising from ignorance, science not having yet shed the light of its discoveries on the mysteries of vegetation; and the wonderful action of phosphates, nitrates, and silicates upon vegetation, although practically known, had not been determined with sufficient minuteness and accuracy to lead to anything like an authentic formula of proportion and quantity. But failures, however complete they may be, in carrying out great ideas, are no arguments against a renewal of efforts; and when those failures, as in the case of steam-engines, railways, reaping-machines, or the application of steam to the cultivation of the soil, are found to act rather as incentives to the ingenuity of men, instead of damping their energy and the buoyancy of their hopes, we know it from the experience of the last thirty years that it is a sure sign that the idea is good, and will be ultimately carried out.

VII.

But there are objections to this system. What system is free from objections? Some say that the mineral matter with which the seed is enveloped, on being dissolved in the soil, will settle immediately around the neck of the roots, which will naturally dive away from it, and it will then become useless to the progress of the plant after it has attained a certain development. I believe that this objection is more specious than real; for every one must have observed that when a seed has fallen upon a manure heap, and there germinated to a plant, if that plant be pulled up, it is found that the roots are very short and shaggy, and do not seem to have penetrated beyond a very limited area, the number of rootlets making up for the deficiency of their length. This seems to me easily accounted for; because the roots, finding in their immediate vicinity a sufficient supply of nutritive elements, have no inducement to dive at any great length in search of them. The instinct displayed by the roots in search of food is truly wonderful, and many examples of their astounding sagacity might be adduced. I have read somewhere the instance of the radicle of a plant diving to the depth of many feet, and fixing itself into a bone that was buried there, and in search of which it had evidently dived at so unusual a distance from the surface. It is not, therefore, unnatural to surmise that the roots of the plants, finding within their immediate vicinity *all* the nutriment required for the plant whose mouths they are, quietly settle in that spot, and contentedly relinquish their erratic propensities.

VIII.

However plausible this and other objections may be, the best test, after all, is the test of experience; and that system, which I have called, for want of a better word,

the incrustation of seeds, must live or die by that great test. A French gentleman has recently come to this country, to submit his invention of a machine for preparing the seed, and the formulas regulating the nature, proportions, and quantities of the mineral substances to be used, to the verdict of English practical farmers; and I am in a position to state that his appeal has been favourably received, and experiments are being made in various parts of England with the view of testing the value of that gentleman's discoveries. Messrs. Burgess and Key have been entrusted with the construction of the simple machine for the incrustation of the seed. This machine consists in a hollow cylinder, suspended by two leather straps from a pulley, to which a rotary motion of about forty revolutions in a minute is imparted, either from a steam-engine or any other motive-power. In the cylinder the seed is introduced mixed with an agglutinous mixture, itself rich in nitrogen; and then the mineral substances, reduced to a fine powder, are added, and from the rotary motion of the cylinder adhere to the seed in a regular coating; this is repeated until the entire quantity has been fixed. In order to prevent the humidity of the agglutinous mixture from acting upon the seed, and causing it to germinate before it is put into the soil, an hygrometric substance is mixed with the mineral powders, which abstracts all the excess of humidity from the glue, and besides dries up the crusted seeds almost immediately.

Previous to his coming to this country, Mons. D'Illiers has satisfied himself by numerous experiments of the value of his discovery; and at the late sowing season, a large area has been sown with his prepared seed in various parts of France, so that at the time of next harvest I shall be enabled to give an authentic account of experiments tried both in France and in England, under every variety of local circumstances of soil, climate, and modes of husbandry.

Norwood, Jan. 8, 1858.

LAND DRAINAGE—ITS ACTION AND EFFECT.

In a former article we pointed out the discrepancy of opinion that existed upon the practice of draining, and we concluded our observations by stating a few leading principles that appertain to the subject. We may pursue these with advantage a little further.

As a surcharge of water in any description of cultivable soil must at all times be injurious, it becomes absolutely necessary that it be discharged as quickly as possible; and as the amount of rainfall is different in different portions of the kingdom, the means applied must have relation to the quantity to be discharged by the drains. Consequently, in districts where the rainfall exceeds 30 inches annually, the means resorted to for its removal must be in relation. The permeability of the soil also forms a strong consideration; the more retentive it is, the nearer together must the drains be placed; and *vice versâ* the greater the porosity of the subsoil. The depth of the drains will depend upon the nature of the upper soil and substratum: if exceedingly retentive, and only slightly permeable, then the depth of the drains must be compensated by the distance betwixt them. On such soils drains of 30 to 36 inches in depth will be found sufficient, the distance between varying from 15 to 20 feet; but when the substrata become more permeable, the depth of the drains should be increased, and the space between them extended. It rarely happens, however, that any soil affected by surface water requires drains more than 48 inches in depth, or will allow a distance of more than 30 feet apart. This may be accepted as a principle necessary in application, upon soils affected only by what is termed *top water*, or such water only as is supplied from above. Upon the permeability or impermeability of the substratum the application must invariably depend; but as many drainers contend that all soils are more or less permeable, it may be well at once to advert to that point. To a certain depth it undoubtedly is the case; but frequently at a depth of 18 inches some of our strongest clays become impermeable, unless for short periods after excessive drought, when, by their having shrunk, fissures have been formed by which water becomes freely admitted, but which, when again saturated, become impervious to the further admission of water. Or, as is the case in many tenacious clays, small veins of *silt* exist in stratified order, and accomplish the object of allowing the water to pass off slowly by their assistance. Professor Ansted, in speaking of the London clay, says, "It is tough, and of course impermeable;" and this has been proved over and over again to be correct.

Much of late has been advanced upon the benefit to be derived by not allowing any of the rain water to be carried off by surface drains, but that the whole of it should be admitted, and pass through the soil to the drains below. The argument advanced in favour of such a practice is assuredly carried too far. It is true that rain water contains some fertilizing properties, more especially as regards the ammonia and nitric acid that become combined with it, but which, at all times minute in quantity, during very rainy seasons exist in the smallest perceptible proportions. Whenever these enter into and become combined with the soil, they are by their affinity immediately taken up by it, and retained to be given out to plants vegetating upon its surface. The greatest amount of injury sustained by soils surcharged with water arises from the exclusion of air and the lowering of its temperature, as well as by the admixture of mineral ingredients with it, which become injurious to vegetation. Air contains substances equally beneficial to vegetation as those contained by rain water: those properties in the latter, before referred to, being taken up in its passage through the air as the rain-water descends to the earth. After long periods of drought, when the air has become highly charged with those substances, the quantity brought down by the first shower that falls is far greater in amount than what is brought down by the next and succeeding showers. In long continuous seasons of rain it ceases altogether. As it is during such seasons that a surcharge of water to the soil becomes most injurious, it is at once apparent that, if a large portion of this matter can at once be carried off from the surface, the necessity of an increased area of drainage below may be dispensed with, especially in districts where the amount of annual rainfall is greatest.

Water in a state of evaporation from a surface discharges the heat also; and, therefore, if no other means exist whereby water can be discharged from the soil, it must remain until sufficient heat is produced by the rays of the sun, or by increased temperature of the atmosphere upon the surface to again convert it into vapour. During this process the heat of the soil becomes diminished, especially at the immediate surface; and a soil of a district of naturally higher temperature is reduced to the temperature of one of

higher latitude or elevation. This effect has, however, been greatly exaggerated. It has been recently computed that the heat lost in the process of evaporation by the sun's rays an inch-fall of rain would be sufficient to reduce the temperature of the soil, to a depth of ten inches, no less than 99 degrees! The more porous the soil, the more rapid is the evaporation; and consequently we have an explanation why crops upon gravelly subsoils become most affected in the early spring months, and at the same time arrive at a remedy in relieving them from surplus water by drainage. The radiation of heat from a surface coming into contact with vapour discharges the heat at the immediate point of contact, and explains the cause of hoar frost when the thermometer shows, at a few inches from the surface, no frost actually existing. The drainage of land, therefore, by lessening the amount of evaporation from the surface, consequently lessens the discharge of heat from its surface, and thereby benefits vegetation.

The third point to be referred to, is the injury sustained by plants whenever mineral substances, entering into combination with water stagnant in the soil, rise to the surface, and become injurious to vegetation. This more especially takes place upon soils highly charged with peroxide of iron, which most soils in a greater or less degree contain, especially those wherever the subsoil is of a red colour. To such an extent does this frequently exist, as to tinge the water passing through it with this red colour, and its deposit.

AGRICULTURE IN CHINA.

HONGKONG, NOVEMBER, 1857.—A revisit to the scenes of the Canton River has impressed me still more not only with the extraordinary beauty of the scenery upon its banks, but also with the singular geological formation of the country. Upon a first view, especially if the attention is absorbed by warlike operations, one does not observe the general coincidence in character between the district of the Pearl River and that of the Yang-Tse. We are struck rather by the points of difference. In the one the eye meets at every point ranges round-topped granite hills; in the other the vision wanders unchecked over a dead flat. Yet both are enormous deltas of alluvial soil, through which the internal waters descend in one large river and a thousand streams. In the north the deposits were spread upon the level bed of a great sea, and silted it up into a solid plain; in the south the rich mud was brought down into an archipelago of granite islets, drove out the sea, and produced a region of rich valleys intersected or dominated by granite mountains. The crops we see upon the banks of the Pearl and upon the banks of the Wangpo owe their luxuriance to the same alluvial qualities of the soil. On the Canton River they are just now gathering their second crop of rice, the bananas are still clustered upon the trees, and the patches of sugarcane look green and reedy. I should have been glad of an opportunity of examining the agriculture of the south more nearly. Three Englishmen at Hongkong resolved, in the spirit of Chevy Chase chivalry, to hunt, or rather to shoot for three days upon the enemy's territory. I was to have accompanied them, but was drawn away by the more imperative duty of accompanying the reconnaissance up the river. On my return I found they had accomplished their vow. Bristing with revolvers and accompanied by five Coolies to each man, they had landed at Mirs Bay, passed through several villages, beat with pointers and beaters the hills overhanging the battlements of a walled city, and, in spite of angry looks and muttered maledictions, had returned with whole skins and a bag of 16 pheasants and some quail.

The best way to see the agriculture of a country is to shoot over it. A landlord who shoots over his estate knows the rotation of crops in every field, and his tenant will not wisely be too persistent in his straw crops. With a view to this same sort of minute acquaintance with the agriculture of the flowery land, I employed some of my enforced leisure at the north in little expeditions after the China pheasants. I used to take a Soochau boat, and go away up the rivers and creeks, some 20 or 30 miles, and anchor off some likely spot for the night. Next morning my servant went to the nearest village and hired three peasants with long bamboos, and we went forth scouring the country. There is no game law in China. The land is free to all, and consequently the result was not great sport. Moreover, every inch of ground was covered by some standing crop, and I had no dogs. Hospitable as the Shanghai folk are, they do not like lending their dogs, and I sighed in vain for my faithful four-footed friends. The only resource was to try whether the habits of the wild pheasant of China, which has cost no one a guinea to preserve, are the same as those of their more costly brethren of England. I used to steal in early morning, and again just before sundown, to the sides of the bamboo plantations. The ground round these plantations, which are always attached to houses, is cultivated in lands, like allotment grounds in England—a land of cotton, another of peas, a third of indigo, a fourth of white turnips, and so on. But in China, as in England, the pheasants are not easy to approach at feeding time. I seldom got a shot at less than 70 yards, and if I brought down my bird "a runner" he was lost to me and my heirs for ever. The fields were all alive with sharp-eyed *indigenes*, who watched the course of the wounded game, and followed it up when I was gone. In the daytime I had a very numerous following of spectators, and I shot many birds of curious plumage for their amusement and for the satisfaction of my own curiosity. It was very critical shooting. It was scarcely possible to point your gun without finding a Chinaman at the end of your barrels; and if you peppered one of these spectators or cotton-pickers by accident, you would be bound up in bamboo thongs and sent to Shanghai in a cage. Altogether, therefore, the October shooting in China is not quite worth following for itself alone. But for the exercise, and as an excuse for exploring the country, it is greatly to be cultivated, and the birds, when you do get them, are very handsome. All the cocks have the white ring round their necks, and, strangely enough, the cocks get up more freely before you than the hens.

After investigation carried on with these opportunities, I am convinced that England has nothing to learn from China in the art of agriculture. It is true the Chinese have no summer fallows; but then they have no stiff clays. They have no couch grass, no thistles contending for the full possession of the land, as we see in Wales; no uninvited poppies, no straggling stalky crops, the poverty-stricken covering of an exhausted soil. At rare intervals we see a large rich-coloured cock's-comb flaunting himself among the cotton; but, generally speaking, there is not a leaf above the ground which does not appertain to the crop to which the field is appropriated. Rice and cotton are the staples of the great district of which I am now speaking. These crops often extend in unbroken breadth over tracts of thousands of acres. The peas, and wheat, and indigo, and turnips, and bringalls lie in patches round the villages. The ground is not only clean, but the soil is so exquisitely pulverized that after a week's rain I have sometimes looked about in vain for a clod to throw into a pond to startle the water-fowl.

We may be accustomed to mark the course of agriculture throughout the breadth of our own land—the light loams of our Lincolnshire wolds, the turnip and barley lands of Norfolk, the strong flats of Suffolk; then westward to the rich pastures of Leicester, the mixed dairy and arable farms of Derbyshire, across the coalfields to the successive and attenuating oat crops on the shores of Bala, and down the valley of the Tivey—yet we shall see nothing like the cultivation of this great plain of China.

The art is exercised under different conditions. The Chinese cultivator is not asked for milk, or butter, or cheese, or mutton, or beef. The Chinaman does not object to a little buffalo or goat's milk with his rice; and if some curious accident should have brought buffalo flesh into his basin, he will eat it. But he rarely or never buys it. In his recent voyage of discovery up the "Great Junk" or "Great Western River," Commander Elliott and Captain Edgell saw droves of buffaloes upon the uplands to the north of Canton, and we know that milk and mutton are common food in Tartary; bnt I am speaking of those parts of China where agriculture is supposed to reach perfection, not of the mountain pastures. Pork, poultry, and vegetables, and the creatures that swim or crawl about his rivers and canals, are the Chinaman's natural dainties. Stall feeding, therefore, would not pay even so moderately (taking sale of stock only into consideration) as it does with us, and grass is only seen growing rank on graves. One or two buffaloes to turn the irrigating wheel and plough the paddy fields, two or three goats, a breeding sow, a quantity of those ugly, long-legged fowls so ignorantly called "Cochin-Chinas" in England, and a flock of ducks and geese—such is the live stock of a Chinese farm which maintains a hundred labourers.

Stable-yard manure, therefore, is scant. Nor is it much coveted. Human ordure is, in a Chinaman's opinion, the only perfect fertilizer. This is collected with the most oppressive care. In the cities and in the neighbourhood of cities enormous dark open earthenware pans offend the senses at every town, poisoning the air, inviting, and too often receiving, the contributions of the passers-by. The privilege of collection is sold for a large price, and the Cantonese have a proverb that a fortune every day passes in that form out of their gates. In the suburbs every cottage has its open earthenware cesspool. In the country every house has its public latrine, ostentatiously placed with its open doorless entrance to the public path. In these temples the Chinese worship with a deliberate solemnity which savours of the ostentatious performance of a religious rite. The numbers and suffocating effluvia of these opposition manure-traps are to an Englishman a never-ceasing horror. They constitute his first and last impression of the country. Like everything else in China, the favour awarded by law and custom to the collection of manure is used as a contrivance for extortion. At Ningpo two immense pans lie opposite to the entrance-door of the first native merchant in that city, awaiting the payment of 2,000 dollars, which is the price of their removal. The boats which convey this produce through the inner waters will bring up close to you at night, and will remove only for a consideration. I knew an Englishman at Shanghai who was obliged to pay 30 dollars upon one occasion of this kind; but then he, in Britannic fashion, had knocked the extortioner into the midst of his liquid cargo.

These details of the "sordida rura" are not pleasant to write; at all times "difficile est propriè communia dicere," but if the object be to depict or to comprehend China, they must be written and read. This manure is sprinkled over the plant. It is too precious to be worked into the ground. The straw and the burnt hulm of the cotton plant are returned to the soil—that is all. The Chinese transplant every root of rice by hand, just as we should transplant young trees, and each has its little blessing of liquid manure as it is sown. This homœopathic system would not do, I apprehend, with our hungry clay lands.

The art of agriculture is, I repeat, exercised under different conditions in China to what it is in England. Give an English farmer a thousand acres of vegetable loam of an unexplored depth—a reticulation of waterways, which enables him to flood at pleasure every acre of his soil—an unfailing supply of manual labour at 4d. a day—and cheap communication, by tidal creeks, with large markets; give him also periodical rains, perfect drainage, and abundance of quickly ripening sunshine, and see what crops of corn and pulse and pot-herbs he would produce. I say nothing of tea, and cotton, and mulberry leaves; for our friend Giles would have to scratch his head a little before he could start on a race to overtake these Chinamen, who are 4,000 years of practice a head of him.

But then, *per contra*, it must be recollected that this park of Ceres is infested by poachers. These happy fields are overrun by extortionate mandarins, pillaging soldiers, marauders, who in small bands are called robbers, and in large bands aspire to be rebels and to be led by "kings," river pirates who levy blackmail, and occasional swarms of locusts which darken the sun. Simple folk may chatter about the horrible injustice of coercing the governing powers of China: but a Government which exacts and does not protect is only a badly-organized brigandage. I see no act of duty in rescuing a fly from a spider or a sparrow from a hawk, yet I do not regard either deed as unlawful. Quite sure I am that the larger interest of humanity would be subserved by any train of circumstances which should bring the Chinese population to comprehend not only our Western notions of probity and honour, but also our Western habits of working those notions into practice.

A curious instance has just occurred of the promptitude and ingenuity with which the Chinese seize upon occasions for extortion. Rumours had reached the ears of the Admiral that some Chinamen were levying contributions in the towns and villages on the banks of the river, and that they were doing so in the name of the English fleet. Commander Fellowes, in the Cruiser, accompanied by Mr. Wade, chief of the interpreter staff, were sent to inquire into this. These officers, with a small force, landed and proceeded from village to village, prosecuting their inquiries under much discouragement, for the suspicious inhabitants apparently imagined that the collectors of the barbarian tribute were come among them. It was only by slow degrees that Mr. Wade gained some credit to his declarations that he was not come to "squeeze." Then the quick eye of the Commander detected a rowboat, built to imitate a man-of-war's boat, but having points of difference enough to show a seaman that it had been constructed by Chinese hands. Soon afterwards Mr. Wade's attention was attracted to a notice posted in one of the more remote villages, and purporting to proceed from the honourable English nation. This proclamation stated that some of the husbandmen had not paid the regulated grain-tax due to the English fleet for protecting their crops, and threatened the defaulters that if the amount were not paid upon a certain day the ships would commence firing upon the villages. Following up this clue, the exploring party at last found that there was a society calling themselves the "Hall of Patriotism and Peace," who were in active collection of this tribute money; and that they actually had a prison well filled with victims within musket-shot of the ships. Of course, the prisoners (six of whom were found loaded with chains) were set at liberty; and the Admiral has circulated a notice in Chinese, disavowing any connection with such exactions. It was believed, however, that the Chinamen who contract to supply the fleet with provisions were at the head of this society; and subsequent inquiry discovered that there was a small fleet of row-boats, some got up to imitate English boats, and others having Chinese equipments and mandarin banners, which lurked by day in the creeks and came out at night. These boats all belonged to the "Hall of Patriotism and Peace," and they levied contributions alternately in the name of each of the belligerent Powers. The grand master of this lodge has been treated to four dozen lashes, and has had his head shaved; but he is no Chinaman if he will not incur a similar flogging for a similar object to-morrow.—Times.

FUNNY RAT TRAP.—A correspondent of the *Genessee Farmer* relates the following funny way of catching rats:—"I build my corn crib on posts about eighteen inches high, made rat-proof except at one of the back corners. Here, where they will like it best, make a nice hole with a spout five inches long on the outside, where they can go in and out and eat at pleasure. Then, if I think the rats are too numerous, I take a bag, after dark, and slip the mouth over the spout on the outside of the granary. Then send "Ben" in at the door with a light, and the rats and mice will run into the bag. Then slip the bag off the spout, and slap it once or twice against the side of the granary. Turn out the dead, and in an hour or two repeat the process. After all are killed, stop up the hole till new recruits arrive, which catch the same way."

THE IMPLEMENTS OF THE FARM—TO IMPROVE OR INVENT.

With reference to the implements succeeding the plough, which still further pulverize the soil, and which finish its surface, as the clod-crusher, the Norwegian harrow, and all the varieties of this important class, it is difficult to estimate in what direction further improvement must be made in their arrangement or construction so as to produce better work. What they have to do is done with admirable precision, so that although minor improvements may be made, no great revolution in their style of working can be reasonably expected. The remedy may be found yet further on. We are quite aware how ungracious is the task of "finding fault;" and having apparently done so much in this way already, if we still continue doing so, we shall doubtless be set down as utterly and in all things heterodox, and as continually indulging in dreams Utopian. But at the commencement of our articles, the task we set ourselves was one which had for its main object the endeavour to point out the probable direction in which agricultural mechanism was likely to progress; and to trace the impulses, if any, which tended to drive men's thoughts out of the long-maintained track of wont and usage. In following out this task, we have not been desirous so much to set before our readers our own notions on the subject as those of others. We have, in truth, been mainly attempting to become the exponent of what "men have been and are now thinking" on the all-engrossing subject of agricultural progress, and our remarks therefore must be considered in this light, rather than as the result of personal convictions.

To come, then, to our rather startling conjecture—namely, that this class of implements now under consideration may be, at some period more or less remote, rendered unnecessary. It may seem strange to some to doubt that clods and hardened nodules of soil are natural concomitants of the cultivated soil. Some do doubt this nevertheless, holding that these defects in cultivated soil are simply caused by defects in the system by which it is cultivated; so that if the soil was properly prepared, these defects would have no existence. Mr. Stephens, in his work explanatory of the "Yester Deep Land Culture," has the following:—"Many of the most costly implements employed on farms, such as Norwegian harrows, Crosskill's clod-crushers, grubbers, rollers, are only used for pulverizing the soil. The occupation of such implements is gone in the Yester deep land culture. The subsoil trench-ploughing, by the double operation, effectually and permanently pulverizes not only the soil, but the subsoil, to the depth of 19 or 20 inches; and the Tweeddale plough itself afterwards maintains the soil in a state of pulverization to the depth of 15 inches, having still a stirred subsoil of 4 or 5 inches beneath a really unusually deep furrow. Experience has fully established that from the pulverized state of the soil in spring, no other implements are wanting for the cultivation of the soil than the plough described above, together with the common harrow with long tines." This is sufficiently suggestive. There can be no doubt that the Yester system is a great fact, and has resulted in an established success; moreover the result of the closest investigation into its peculiarities can discover nothing which prevents its adoption in other districts. Indeed, the facts established by it afford the strongest argument in favour of the plough—when philosophically used—as being in reality the best and cheapest implement which can be used for the cultivation of the land. Nothing, in our opinion, would tend so forcibly to lead away many minds from attempts to supersede the plough, as the wide adoption of the Yester, or some similar system, which seems to afford the best work of which the plough is capable; and gives the deeply-pulverized seed-bed with inverted furrow, so strenuously insisted upon by all thinking agriculturists who advocate its use. We are glad to see that attention to this system is becoming widely spread. It certainly does not seem to follow—at least there is no reason to conclude—that these clods and hard nodules of soil should be an invariable concomitant of some, if not the majority, of cultivated soils. One prolific cause, in heavy clay soils, of these clods, is the stirring of the soil while in a wet state. Now in the Yester deep land culture there is a complete cessation of ploughing "from the autumn cross ploughing of the stubble, to the making up of the land for turnips in spring." The soil remaining in a pulverized state, the farmer is in a measure independent of the weather both in winter and spring, "as the land can wait for the best weather." There seems then a probability that good thorough cultivation will put and *maintain* the land in such a state, that many implements which are now considered—and are indeed—essential, may be entirely disused. There is no doubt also that the power of steam applied to the working of cultural implements will tend greatly to prevent the formation of clods and a hardened surface, by doing away with the poaching and puddling of the horses' feet. An eminent man once remarked to us, that in view of the simple elementary implements, the plough and the harrow, which were for so long a period considered the only ones essential to secure good cultivation, the long array of complicated machines to be seen at our great agricultural shows was really very puzzling, and was calculated to make one wonder whether they were really all required or not. It will be odd indeed if experience in cultivation brings us back again to the use of these two implements only, the plough and the harrow; the experience of the Yester system points at all events to this result. There is such a thing as a *variety* of machines being necessitated solely by the badness of a system of procedure.

Broadcast and drill-sowing are now known as respectively the "old and the new" school of procedure. There is something thoroughly sound and satisfactory in the principle of a corn drill; and something as sound in the mechanism by which it is carried out. The "swing lever" was just the thing wanted to take the machine out of the category of doubtful, and place it in that of accomplished pieces of mechanism. But the "drill," looked upon by many as the ultimatum of sowing machinery, beyond which no progress can be made, is perhaps destined to be rivalled by another machine acting on a different principle. A rising class are now advocating the "dibbling" system as productive of infinitely higher results than even the drill; that it is, in fact, as much above this machine in efficiency as the drill is above the broadcast system. If these opinions with reference to the value of the dibbling system gain ground—and there is apparently too much soundness in the principle to allow of its dying away, without gaining a wider trial than it has yet met with—a wide field in which to exercise their ingenuity will be

opened up to our mechanicians. The problem to be solved, in the perfecting of a dibbling machine capable of a higher rate of working and economy than has yet been effected, is, however, a much more difficult one than may at first sight be imagined. Unfailing deposit of the seed, uniformity of depth in its deposition, and undeviating regularity of operation, must all be attended to. The weight of evidence is apparently in favour of the deposition of several grains in the hole rather than in that of one or a "single" grain only.

It is obvious that steam-power, if brought into requisition for cultivating the soil, will be made to aid in succeeding operations—in our sowing, and in our harvesting. In view of this extended application of the new power, considerable modifications will be necessitated in the management of our "drills." To obtain the full economy and efficiency of steam, its operation must be as continuous as possible: once set in motion, the machine which it operates must or should go on until its work is performed: all stoppage to arrange or modify its mechanism is just so much loss, and must therefore be avoided. Hence with steam-drawn drills a higher class of workmanship, with mechanism calculated to make the machine meet its own wants with as little human interference as possible, will inevitably be required. We fear that the attempt to apply the present machines — admirably adapted as they may seem, and indeed are, to our present system—to steam-power will only result in disappointment, with loss of time and money. As we have before said, the new power will necessitate the use of new implements and machines; not necessarily new in the principle of their operation, but new in mechanical arrangements, suited to the vastly different circumstances under which the processes they are designed to serve, will be carried when the new power is predominant.

The same remark applies to hay-making machines and reaping-machines.

While examining with a pardonable wonder the curiously complicated, but withal most efficient machines used in the various branches of our manufactures, as the cotton, the wool, or the silk, we are apt to think it strange that the same facility of mechanical adaptation has not been observable in agricultural machinery. But, while far from ignoring the fact that comparatively little has been where much might have been done, we should remember that the difficulties surrounding all attempts to adapt finely constituted mechanism to agricultural operations are much greater, indeed generally of a totally different kind, than those which surround similar attempts in manufacturing mechanism. On this point, we venture to quote a few remarks given elsewhere:—"In many of the processes of our manufacturers, however much we may be astonished at the precision with which operations are carried on by the aid of machinery alone —operations which seem to demand some share in the human will—the obstacles which presented themselves in adapting mechanism to carry on these have been of a nature comparatively easy to be overcome. The nature of the material to be operated upon is generally unvarying; or at least, where changes do occur, they are of such a nature that simple mechanical arrangements obviate all inconveniences resulting therefrom. Not so, however, with reaping-machines. The material to be operated upon is continually changing; and the difference between a rainy day and a dry one—between hilly ground and level—between laid grain and standing—is just all the difference that is required to make the material either that which affords facilities to these machines in cutting, or, on the other hand, of throwing such obstacles in their way as to render it almost an impossibility to cut it at all. But the capability of *merely* cutting corn under all circumstances of time, place, and condition, is not the only work which a reaping-machine has to perform. The gathering-in and distributing of the corn after being cut, ready for the binders, is an equally important part of its duties. Nor, in fact, does its mission end here: a perfect reaping-machine should be capable not only of cutting the corn with undeviating regularity, but of arranging it into bundles of defined and unvarying size; leaving, as the only labour to be performed by the hand, the tying of these bundles, and the placing of them in the field in the form of 'stooks.' Performing this wider range of duties, the machine is better distinguished by the American term of 'Harvester.' As in machine-spinning, so in machine-reaping, the less there is for human hands to do, the more perfect the machine. But herein lies the difficulty of effecting machine-reaping: as we have shown, the material on which, and the circumstances under which it operates, are varying in character, and do not present that uniformity which opens up much hope that with our present system of culture, we shall be able to rival the automaton performance of our manufacturing mechanism."

In this department of agricultural mechanics the implement-maker must be aided by the farmer, and exactly in the way we have indicated when treating of the application of steam-power to culture. If the preparation of the land previous to the operation of the cultural-machine is, as we have endeavoured to show, essential to the full perfecting o the steam-working system, it is no less essential we conceive to the perfect working, or at least greatly increased efficiency, of the reaping-machine. And here comes, in full force, the opinion of the gifted mechanician whose words we quoted at the conclusion of a recent article, and to which we again refer the reader. If, then, the agricultural mechanic can obtain fields calculated to aid the operation of his machine, rather than to retard it and throw difficulties in the way of its performance—as too many fields do now; if, moreover, by the more extensive adoption of that system of sowing which, as its advocates say, gives us thick strong straw, little liable to be laid by winds and rain, there can be little doubt that our reaping-machines will soon be brought to that state of mechanical perfection which will enable them to carry out those complete operations that will be demanded of them should the power of steam ever be adapted to their working. What these complete operations are we have endeavoured to show.

SIZE OF FARMS IN AMERICA.—In the wheat region, south of Lake Ontaria, the farms are usually from 150 to 200 acres in extent, though many are much larger. The farmhouses are roomy and comfortable, impressing one favourably with the condition of the occupants. The female members of the family have ample employment in the cleaning and cooking departments, and the table at the different meals is loaded with a profusion of dishes. House servants are dispensed with as far as possible. Butcher-meat appears at breakfast, dinner, and supper. The Americans no doubt eat a vast deal too much of such stimulating food. Indeed, I do not think that any class in England consumes so much butcher-meat as all classes do here. It is a remarkable circumstance that farms have a tendency to decrease in size more rapidly where the land is poor than where it is rich.—*North America; its Agriculture and Climate. By Robert Russell.*

INQUIRY RESPECTING THE QUANTITY OF NITRATES CONTAINED IN THE SOIL AND IN THE WATERS.

[TRANSLATED FROM THE FRENCH OF THE "JOURNAL D'AGRICULTURE PRATIQUE."]

In a former paper I endeavoured to demonstrate that saltpetre acts directly upon the development of plants. I mentioned the experiments made upon the employment of nitrate of soda of Peru in extensive farming, and called to mind that nitrates had been detected, for a great length of time, in arable lands possessed of a high degree of fertility, by Bowles, Praust, and Einhoff, in the waters of brooks, rivers, and springs; in meteoric waters by Bergmann and Berzelius; and, more recently, by the remarkable labours of Messrs. Bineau, Henri St. Claire Deville, Brandes, Liebig, Bence Jones, and Barral.

In the researches I have had the honour to lay before the Academy, I proposed to myself to extend the investigations of my predecessors, by determining what, at a given moment, is the quantity of nitrates contained in a hectare of arable land, a hectare of meadow, a hectare of forest land, and a cubic metre of river and of spring-water.

The nitrates have been found in forty samples of earth; but, before presenting the result of these discoveries, I must first make known the circumstance which has induced me to undertake the work.

I had had occasion to observe that the plants brought from the kitchen-garden of the ancient monastery of Liebfrauenberg contained considerable quantities of nitrates. Beet-roots, which I had cultivated in 1854 at the request of M. Peligot, contained also so large a proportion, that it became nearly impossible to extract the sugar from them.

Each year the kitchen-garden received in autumn a heavy manuring with rotten stable-dung. The soil is light, being a disintegration of the sandstone of the Vosges, and other motley kinds. The water is not retained in it, because the porosity of the earth descends to a considerable depth.

On the 9th of August, 1856, after fourteen days of drought, accompanied with great heat, we took some vegetable earth from a bed, and to one kilogramme of that earth, dried in the sun, we applied the equivalent of 0.211 grammes of nitrate of potash. The litre of dry earth, weighing 1.500 kilos., we have 516.05 grs. of nitrate to the cubic metre; so that on the 9th of August we might estimate the saltpetre contained in a hectare of the kitchen-garden at 1.055 kilos., taking 0.33 inch as the mean depth of the vegetable mould.

Such a proportion of nitrate, in a soil very heavily manured, has nothing surprising in it; in fact, to incorporate a soil well mellowed with stable-dung in an advanced state of decomposition, with either ashes or marl—to dig it thoroughly, so as to mix and let in the air to the whole mass—to form trenches to prevent stagnant water from accumulating, is, in fact, equivalent to manuring, and prepares a field to yield abundant harvests. Well, a little reflection will show us that this is exactly the process we adopt when we form an artificial nitre-bed. The only difference lies in that, in a moist climate, the nitre-bed ought to be sheltered, in order to preserve in the earths salts so soluble as nitrates; and that, however little continuous it may be, the rain does not fail to draw, or at least to penetrate into, the adjacent subsoil. Thus, from the 9th to the 29th of August, it rained every day at Liebfrauenberg, and they measured in the udometer 0.053 in. of water. The 29th of August, immediately after the rain had ceased, we collected earth in the same bed from which we had taken it on the 9th: after drying, 1 kilo. of this earth yielded 0.0087 grammes of nitrate; consequently, in 1 cubic metre, the equivalent of 0.13 kilos. of nitrate of potash, or 45 kilos. per hectare: the greatest part of the saltpetre had, therefore, disappeared from the surface of the earth.

In the month of September it rained fifteen times, and there fell 0.108 in. of water. On the 10th October, after fourteen days' drought, the soil of the kitchen-garden, under the influence of a continued wind, had lost its excess of moisture, and had become dry enough to require watering. From earth taken from the foot of a wall breast-high, after having been dried, was obtained 0.298 grammes of nitre per kilo., or 447 grs. per cubic metre, or 1.490 kilos. per hectare, which rather surpasses that obtained by the dose on the 9th of August. The alternations of drought and moisture the soil had undergone, explain the enormous variations that we have noticed in the proportions of nitrates found in the soil. As to the great quantity of these salts, it proceeds, beyond a doubt, from the prodigality with which we manure, at all times, a kitchen-garden—the true type of intense culture. It is proper, therefore, to apply doses of saltpetre to soils which never receive manure, such as forest-lands, or which are only slightly manured, as lands tilled under a normal cultivation.

I have examined seven samples of forest-soil. The earth taken on the 27th October in a forest of pines near Ferreste, in the Upper Rhine, furnished no indications of nitrates.

The earth of a pine-forest, situated on the summit of a mountain of the Vosges, and in such a position as to be watered only by the rains, contained, on the 4th of September, the proportion of 7 grammes of nitrate of potash per cubic metre.

Sand taken on the 15th October, in the forest of Fontainebleau, contained per cubic metre the equivalent of 3.27 grammes of nitrate of potash.

In a heath soil collected on the 15th August, in the forest of Hatten (a short distance from the Rhine), we found the equivalent of 12 grammes of nitrate.

In meadow-lands, taken in September and October on the banks of the Saüer, in a valley of the Vosges, and a pasturage situated near Roedersdorf (Upper Rhine), the proportion of nitrate of potash has varied from 1 to 11 grammes per cubic metre of earth.

Of nineteen samples of arable earths, of good quality, taken in September and October in the valleys of the Rhine, the Loire, the Marne, and the Seine, four yielded no nitre. The lands which contained the least were taken from a field of maize at Hoerdt (Lower Rhine), from the vineyard of Liebfrauenberg, and from a field of beetroots on the banks of the Saüer. The cubic metre of earth did not contain, respectively, more than 0.8 grammes, 1.28 grs., and 1.35 grs. in equivalent of nitrate of potash.

I had not waited for this last result, in seeking nitrates in the calcareous *amendements* which are applied to the

soil in large dressings. The shell-marl formed, as we are aware, of the debris of cockles, had become incorporated with the earth we are about to speak of, in consequence of an application of 70 cubic metres per hectare. In 1 kilogramme of this shell-marl, recently taken from the pit, I was not able to detect the least trace of nitrate.

A very white marl, from La Chaise, near Louzouer (Loiret), examined immediately after its extraction, contained the proportion of 7.2 grs. of nitrate of potash per cubic metre. In the marl of the same deposit, extracted in 1853, and which, since that time, had remained in a lump on the edge of the marl-pit, we obtained from the same volume 19 grammes of nitrate. A very argillaceous marl, from the hills of Chaumont, contained 25 grammes.

The chalk at Meudon is extracted from three overlying workings. The limestone taken from the upper stratum, in a cutting actively worked at a point where the quarriers were engaged, contained per cubic metre the equivalent of 16 grammes of nitrate. A fact worthy of observation is, that we have found no nitre in the inferior (lower) beds of chalk. When we know what is the mass of calcareous matter we incorporate with the soil in a dressing of marl, we can understand that, in spite of the weak proportion of nitrates they contain, they must be sought for, since they may form part of the substances which are held enclosed in the marls in only very minute quantities, but which at the same time are not less efficacious, such as phosphates of lime and alkaline carbonates.

With some exceptions, we have met with saltpetre in the earths examined in sufficiently weak proportions. But we ought not to forget that the experiments have been executed during a rainy autumn, and that the rain tends to take away, or at least to displace the nitrates. We have ascertained, in fact, that the nitre of a cubic metre of earth from a kitchen-garden has varied from 316 to 13 grammes, according as they were extracted before or after the occurrence of the rainy days. What is, above all, necesssary to observe in the results obtained, is the fact of the frequency of saltpetre in vegetable earth, whether it belongs to the forest-soil, situated at such a height above valleys, that it receives as manure nothing else than the rain, or makes part of a tilled soil to which the most intense manuring is applied.

As water tends to dissolve the nitrates, we should expect to find a stronger proportion of these salts in a soil moderately manured, kept sheltered from the rain. I have, in point of fact, met with very remarkable quantities of saltpetre in the soil of hothouses, which has more than one analogy with artificial nitre-beds.

In one kilogramme of earth of a hotbed in the Jardin des Plantes, I found the proportion of 6 centigrammes of nitrate of potash, or 89 grammes per cubic metre. A kilogramme of earth, taken from another hotbed in the same establishment, has yielded the equivalent of 6 decigrammes of nitrate of potash, or 804 grammes per cubic metre.*

Our learned contemporary, M. Moquin Tandon, having readily authorized me to take from the hothouse of the botanic garden of the College of Medicine the samples which I required, I have been enabled to detect, in 1 kilogramme of the light black mould from the surface of the frame, the equivalent of 0.121 grammes of nitrate of potash, or 161 grammes per cubic metre.

In one kilogramme of strong earth, taken at the depth of 30 centimetres below the light mould, we obtained the equivalent of 0.107 grammes of nitrate of potash, or 185 grammes per cubic metre. It will not, perhaps, be useless to observe here, that it is precisely in this same hothouse of the College of Medicine that M. de Luca has made his interesting experiments upon the nitrification of potash by the elements of the atmosphere.

Whether the nitrates, of which I have given the large dose in the soil of hothouses, have their origin in the atmosphere, or that they may be formed as the result of modifications which the organic matters in manure gradually undergo, in presence of alkaline or earthy bases; or, still further, that they result simply from the successive accumulations of nitrates brought by the water employed in watering it; or, lastly, from these various causes united; it is still clear that their continuance in the earth depends essentially on this circumstance, that the pluvial waters do not carry them away. Setting aside also the favourable influence of the temperature of humidity, everything leads us to believe, that it is in a hothouse that a manure produces its maximum of beneficial effect. On this subject I may be permitted to offer some reflections.

In the actual state of our knowledge it is natural to attribute the azoteous principles of vegetables whether in the form of ammonia or of nitric acids, regard being had to the question of ascertaining if the azote of the acid does not pass into the state of ammoniac under the influence of vegetable organism. The azote of albumen, of casein, and of fibrine of plants, has very probably formed part of a sal ammoniac or a nitrate. Perhaps we might add to these two salts a brown matter which we obtain from manure. But even with the adjunction of this matter, still so imperfectly known, it remains an established fact that every immediately active element of a manure is soluble, and, consequently, that a manured soil, when exposed to continued rain, loses a portion more or less strong, of the fertilizing agents which have been given to it; besides, we constantly find in drainage waters the true lixiviate of the land—nitrates and sal-ammoniacs. And if it be true that the summits of mountains and elevated table-lands have no other manure than the mineral substances derived from the rocks from which they are found, and the meteoric waters, it is not less so that in the most ordinary conditions of cultivation, a soil strongly ameliorated yields to the pluvial waters which pass through it more fertilizing principles than it receives from it. In giving to the soil a coat of manure in a slightly advanced stage of decomposition, containing by that means, rather the elements of ammoniacal products and nitrates, than of those salts themselves, the inconvenience resulting from the action of protracted rains, is less than if they gave it rotten dung, in which the soluble salts already predominate. Besides, amongst the incontestable advantages arising from the application of liquid manures, I think we ought to place in the first rank, that of bringing to the plants cultivated, only matters properly modified to be absorbable, offering them to the plants only in proportion to their wants; the true dressing bearing a certain resemblance to the most delicate proceedings of experimental physiology, and which preserves the manure from the dissolvent action of the rain waters.

If the meteoric-waters over which the agriculturist has no command, produce often an effect unfavourable to his cultivation, by their abundance and, above all, their unseasonable intervention, it is not thus with spring and river waters, brought by irrigation; or those which are held by absorption in a valley in a suitable state of moisture. These waters, when we measure them to the soil, yield to it the entire of the useful substances they hold in solution or in suspension; calcareous and alkaline salts, carbonic acid, organic matters, &c., and in order to show in what large proportion these dissolved or attracted substances are introduced, I shall recapitulate that in a series of experiments which I had under-

* These earths had not the same density; but I report from memory the weight of the litre of each earth examined.

taken in order to determine the volume of water necessary to irrigation in our climate during summer, I was able easily to produce an absorption per hectare on land strongly seeded with trefoil, ninety-seven cubic metres of water every twenty-four hours. This was, after all, not more than a watering to the extent of 9.07t. of liquid per square metre. It was casting upon the soil a covering of water of less than 0.01 in. thickness.

Amongst the salts useful to vegetation conveyed by irrigation to the soil, we ought to distinguish the nitrates, the fertilizing effects of which had not escaped the sagacity of M. Henri Sainte-Claire Deville in the classic work he has published on the composition of potable waters, and from which he has deduced as a consequence, that the waters of springs and rivers are for meadows a powerful manure by the silica and alkalies they bring and by the organic substances and *nitrates*, in which the plants find the azote indispensable to their organization.*

It is not necessary to insist upon the interest that might be attached in detecting in the waters so active a manure as saltpetre; the results at which I have arrived, by showing to what an extent the proportion of that element varies, justify besides the opportunity of executing similar researches.

Thus I have scarcely been able to ascertain the nitrates in those enormous masses of water contained in the mountain lakes of the Vosges.

The water of the Seven Lake with the same valley, a little below Lake Stern, and from whence flows the Doller, has yielded per litre the equivalent of .07m. of nitrate of potash.

The pond at Soultzbach, near Woorth (Lower Rhine), formed by the dam of the little river of Soultzbach, is surrounded with mountains of sandstone of the Vosges. In a litre there was but .03m. of nitrate.

Spring Waters.—I have examined the waters of fourteen springs. The poorest in nitre were those of Liebfrauenberg, and of the ruins of Fleckenstein. Both proceed from the sandstone of the Vosges, and the litre contains from 0.03m. to 0.14m. of nitrate of potash.

The spring waters in which I have found the most saltpetre are those of the Ebersbronn (Lower Rhine), and of Roppurtzwiller (Upper Rhine), which yielded respectively 14 and 11 grammes of nitrate. These waters are used for irrigation.

Waters of Rivers.—Of the river waters analyzed the least charged with saltpetre are those of the Seltz and the Saüer, tributaries of the Rhine, which respectively yielded 0.07m. to 0.08m. per cubic metre.

Those which contained the largest proportion of nitrate are the Veste in Champagne, and the Seine; the water of the former holding 12 grammes, and that of the Seine 9 grammes per cubic metre. This last result is deduced from six determinations made between the 29th of November, 1856, and the 18th of January, 1857. In 1846 M. H. Sainte-Claire Deville detected in the water of the Seine, in nitrate of soda and magnesia, the equivalent of 18 grammes of nitrate of potash per cubic metre.

At low water the Seine delivers at Paris per second 75 cubic metres, and during the average waters 250 cubic metres. In adopting 9 grammes for the nitrate, we find that at low water, in 24 hours, the stream carries to the sea the equivalent of 58,000 kilos. of nitrate of potash, and the medium waters 194,000 kilos.

If, now, we consider that the volume of waters of the Seine is far inferior to that of the generality of the large streams which furrow the different continents, we shall comprehend how immense is the mass of saltpetre continually borne away to the hydrographic basins; and with what incessant activity the phenomena which determine the nitrification must act on the surface of the globe.

Water of Wells.—I have generally found more nitrates in wells sunk in villages and rural workings than in springs and rivers; but here again the proportions have been most variable. For example, the water from the well of Bechelbronn, which indeed is not exempt from some traces of oil of petrolium, contains only indications of nitrates; whilst the water of the wells of Woerth and Freischwiller (Lower Rhine), sunk in the lias marl, exhibit from 66 to 94 grammes per cubic metre. But it is in the wells of the great cities that we find the largest quantities of nitrate. This fact has long since been known, and M. Henri Sainte-Claire Deville has found in water raised at Besançon the equivalent of 198 grammes of nitrate of potash per cubic metre. The proportion of nitre that I have met with, in the waters proceeding from 40 wells selected in the twelve arrondissements of Paris, is still larger. The experiments have been executed by two processes which I have employed comparatively—the decoloration of indigo, and the ingenious method we owe to M. Pelouze. The well waters in which there was the least nitrate came from the following places:—

	Nitrate of Potash.
Rue Guérin-Boisseau, in which we detected per cubic metre the equivalent of	200 gr.
Rue Saint Martin	225
Rue Sainte Georges	238
Rue des Petites-Ecuries	258

The waters which have yielded the most nitrate were those from the wells in the most ancient quarters. In the water of a well in

Rue du Fouarre, we found per cubic metre the equivalent of	1,031 gr.
Rue du Foin Saint-Jacques	1,500
Rue Saint-Landry	2,093
Rue Traversine	2,165

In two wells on the grounds of market gardeners in the Faubourgs, the cubic metre of water contained 1.268 k. and 1.546 k. of nitrate. It is thus seen that 100 cubic metres of these waters, exclusively destined for watering the grounds, convey to them from 120 to 125 kilos. of saltpetre, the utility of which as a fertilizer cannot be disputed, especially when we know that in summer a hectare of market-garden ground absorbs from 30 to 40 cubic metres of water per day.

The large proportion of nitrate found in the water of the wells of the capital is undoubtedly due to the modifications to which the organic matters with which the soil is constantly impregnated are subject. The purity of the air and the water, the effects of which manifest themselves so powerfully upon the public health, must be deeply affected with it. I have shown at another period that the rain, after having swept, in crossing, the atmosphere of a large city, holds in solution or in suspension much more ammoniacal and putrescent organic principles than when it falls at a distance in the country. To-day I have shown that the water of wells, after being

* *Annales de Chimie et de physique*, 3rd Series, v. 23, p. 52. The following is the summary of the labours of M. Sainte-Claire Deville. "These analyses establish, 1st. The importance of the portion of silica in potable waters, which M. Payen had previously found in great quantity in the water of the wells of Grenelle. 2nd. The part which this agent, in connexion with the azoteous matters of the waters, takes in the fertilization of meadows. 3rd. The similar part which we ought to ascribe to nitrates in the action of water as manure, and consequently the importance of the nitrous elements in many cases. (1.) Water taken the 22nd October 1856. I mention the dates, because in the waters, as in the earths, the proportion of nitrates is not at all periods the same. (2.) Water taken the 25th October, 1856. (3.) Water taken the 24th August, 1856.

filtered through a soil similar to a nitre-bed, is tainted with substances evidently injurious. So true is it that a condensed population carries in itself the germs of insalubrity.

At Paris, by reason of the geological medium which it passes through, the water collected in the wells is not drinkable; nor is it drunk, or made use of in the preparation of food. According to that, we might suppose the population completely sheltered from the inconveniences which it would produce. This would be an error; for it is easy to prove that every inhabitant takes every day the whole of the substances dissolved in a certain volume of that water.

First, we are convinced that within the city walls the lixivium (*coupages*) of the heavy wines and alcoholic drinks are mixed with the water of the wells; and it is asserted that the bakers employ no other in making the bread.

One thousand kilogrammes of flour, in making into bread, require for the different leavens and dough 617 litres of water.

For produce they obtain 1,375 kilogrammes of bread, containing necessarily all the soluble substances of the 617 litres of water.

In 1 kilo. of bread there is therefore all that is found in 45 centilitres of well water. Let us next see which nitrates this water introduces.

The well water of the Hotel Scipion, the bakery of the hospitals, contains per litre the equivalent of 0.31 gr. of nitrate of potash: this is one of the waters least charged with salts.

One kilo. of bread prepared with this water should contain 0.1¼ gr; and 1 kilo. made with the water of the well of Rue Saint Landry contains the equivalent of about 1 gramme of nitrate of potash.

In these weak proportions it is doubtful whether the nitrates are unhealthy; but what renders their presence in the bread unpleasant is, that it is the indication of organic matters, evidently proceeding from suspicious sources: from domestic waters for instance, or the infiltrations that escape from the 60,000 privies sunk below the soil. We must not forget, also, that every year, by the rising of the Seine, the subterranean inundations put in communication the inferior with the upper strata of the soil, in the latter of which are the receptacles of the night-soil, &c., and that the waters in washing the soil convey, in what they draw, spores of cryptogamic vegetation—those mouldinesses always hurtful, and so much more to be dreaded that their organism, apparently so frail, resists nevertheless the temperature of the oven in baking bread, as laid down by M. Payen, and more recently by M. Pagiale.

In a memoir read before the Academy in 1852, I have already spoken of the disgust inspired by the well water when we know, and no one is now ignorant of it, that they are employed in the bakeries. Already, if I am well informed, the administration of the hospitals have made arrangements for procuring the water of the Seine to the bakehouse of Scipion. This is undoubtedly an example that will be imitated; for we cannot comprehend why, at Paris, they should persist in preparing bread with impure water.

From the whole of these investigations we may justly conclude that with regard to the fertilizing principles they bring to the earth by irrigation or absorption, the waters which circulate on the surface, or at a slight depth, act much more by the saltpetre than by the ammoniacs which are found in them. In my paper on the ammoniacs of the waters I have shown that river water rarely holds above 0.2 gr. and spring water 0.02 of alkali per cubic metre; now the results hitherto obtained indicate in a cubic metre of the same waters the equivalent of 6 to 7 gr. of nitrate of potash, answering, as azoteous manure, to 1.10 gr. of ammoniac. These numbers are very nearly the same as those deduced by M. Bineau from his chemical studies on the waters of the basin of the Rhône.

The geological constitution of a country has likewise the most decided influence on the proportion of saltpetre. This influence, which is stated by M. Bineau, is above all revealed in the course of this work. Thus, in the lakes hollowed in syenite the waters exhibited only traces scarcely appreciable of nitre; those which proceed from the red or quartzose sandstone of the Vosges appear not to have more than 0.5 gr. per cubic metre; whilst in the calcareous lands, as they belong to the trias, to the jurassique country, to the cretaceous group, or to the tertiary deposits above the chalk, the spring and river waters have furnished the equivalent of 15 gr. per cubic metre of nitrate of potash, and the proportion has varied from 6 to 62 grammes.

If in the springs and rivers there is generally more of nitrates than of ammonia, the contrary seems to exist in rain and snow water and dew.

From experiments continued for six months in 1852, we established that meteoric water, collected from a great distance from inhabited places, contain on an average 0.74 mgr. of ammonia per litre. Since then Messrs. Lawes and Gilbert have found a number nearly similar, by observations during a whole year, at Rothamstead.

In the summer and autumn of 1856 I have examined ninety samples of rain collected at Liebfrauenberg. In seventy-two of those waters it was possible to detect the nitrates, which agrees with what M. Barral has stated; and the quantitative results to which I have arrived, although leaving perhaps something to wish for, nevertheless authorise me in believing that rain, when it falls in the middle of fields in the proximity of extensive forests, contains much less nitric acid than ammonia.

BOUSSINGAULT,
Member of the Academy of Sciences, and of the Central Society of Agriculture.

THE ADVANTAGES OF A DAILY REGISTER OF THE RAIN-FALL THROUGHOUT THE UNITED KINGDOM, AND THE BEST MEANS OF OBTAINING IT.

That the advantages of an accurate register of the rain-fall would be abstactedly useful, no one would for a moment dispute. We would even say that for certain practical purposes—such, for instance, the use of water-courses as a motive-power, the regulation of flood-gates in flat districts exposed to inundations, or even for the purposes of irrigating and warping—such an accurate register as Mr. Denton advocates is indispensable, if certain success be aimed at, and nothiug left to hazardous and reckless speculation; but we certainly differ from him, when he attempts to attach to this accurate and universal register a necessary action and influence over the drainage of land.

It is evident that drains are not meant for a constant and never-ceasing action. Their use is to discharge water when there is an excess of water to discharge. Where much rain falls upon the surface they underlie, their action is more frequent than in districts where a less quantity of water falls from above; but on account of that more frequent use, provided the outlet they

offer to the supply of water be sufficient, no one would think of laying them at closer intervals or at greater depths than in soils of a similar nature, but situated in less rainy districts. The nature of the soil itself—the more or less retentive texture of its constituents—the topographical position and plane of the surface, are the objects of much more immediate and indispensable considerations for the regulation of depth and intervals than the quantity of rain that may generally fall during a whole year. A rain gauge, even assuming that the instruments now used are accurate—and Mr. Denton tells us that upon this important point there is a conflict of opinions—can only give us the quantity of rain that directly and perpendicularly falls over a plane area; but it does not register the quantity of water which, in addition to that direct fall, flows over underlying lands from neighbouring hills, or surface undulations, and other causes, in which case, the register of the rain-gauge is of no earthly use. Again: it often happens, even in those districts where the rainfall is the least, that at any moment showers, such as frequently accompany thunder-storms, will rush upon the land, and in a few moments pour upon its surface a large quantity of water, which of course the drains must be capable of discharging.

It is very obvious that in wet climates the drains are brought into more constant use than in drier ones. But we contend that this is the only difference, and that difference can hardly be practically taken into account in the laying of drains; for however small the yearly average fall of rain may be, the drains may be called upon to discharge at any given moment quite as large a quantity of water, although less frequently, as in lands situated in more rainy districts. We cannot, therefore, understand what practical use in drainage the accurate register of rainfall can be; for the only local circumstances we know of, that must regulate the depth and intervals between the drains, is, as we have said: the nature of the soil itself, and the topographical position of the land in respect to the supply of surface water that may flow from adjacent rising grounds, to a much larger amount than that given by the rain-gauge, and of which that instrument cannot give the most fractional idea. Besides, whatever the fall of rain may be, or, in other words, however often the drains may be called upon to act, this cannot interfere with the intervals and the depths at which the drains should be placed; for the extent of those intervals is exclusively determined by the nature of the soil, and should be limited only by the point where the action of the drains ceases to act laterally—the limit of the action of one line of drains ending where the action of the next line begins.

The phenomena exhibited by the movement of liquids are ever the same. If a shower falls over the great desert of Sahara, where rain is seldom seen, its descent downwards through the soil, sandy though it be, is regulated by the same opposite forces of gravitation and capillary attraction as when falling in countries where rain falls more frequently. It is true drains would be more useful in one case than in the other; but surely an accurate register, such as Mr. Denton advocates, is not necessary for ascertaining that plain fact, the experience of the most ignorant *old inhabitant* of a district being amply sufficient. In all cases where thorough drainage is aimed at, drains must be laid under every variety of circumstances, at such a depth and at such intervals that the limit of the action of one line terminates where that of the other begins, whether that action is to be exercised only one day in the year, or two hundred days.

When we say that there are districts with a rainfall of 50 inches, and others with only 25, we do not mean that every shower falls with twice the intensity upon the one as upon the other: we only mean that rain falls twice as often, or, in other terms, that the drains are called upon to act twice as often in one case as in the other; but to all intents and purposes the quantity of water which they must evacuate in a given time is pretty much the same.

Then, there are other circumstances which have a direct influence upon drainage, which the rain-gauge cannot reach; and these circumstances, as regards that influence go far to compensate the difference of rainfall between the western and the eastern districts of this country—we mean the fall of snow. It is a well-known fact that snow is a rare occurrence in Cornwall and Devonshire, whereas it accumulates sometimes to a great depth in the eastern counties. When that mass of snow comes to thaw, with all its accumulations against every obstacle, what becomes of the land, in the spring of the year, when a high temperature and dryness of soil are necessary for the purposes of vegetation, if, on account of the register of the rain-gauge, a deviation from the general rules of drainage had been ventured upon? It strikes us that no rain-gauge has yet been constructed so as to give anything like an accurate datum of the quantity of water brought down in a fall of snow, drifted as it generally is by a high wind.

As regards the means of effecting the general register of rainfall in this country, at a cost of some £26,000, as advocated by Mr. Denton, we are pretty confident that no Chancellor of the Exchequer will ever be found to debit his budget with such an item as this, even if it were admissible that sufficiently diligent and careful individuals could be found to undertake such a task for the remuneration of five pounds per annum!

Apart from this anxiety of Mr. Bailey Denton to prove too much, and to overstretch the importance of the measure he advocates, his paper is replete with instructive facts, and shows a great accuracy of observation, and wonderful ingenuity in arranging the results of his experience. His tabular records of the Hinxworth drainage are certainly the best arranged we have ever seen.

THE CLEANING OF CORN FROM THE STRAW.

Knocking, scutching, or rubbing out grain from the straw, is an operation in which comparatively little improvement is required. With a thousand or twelve hundred revolutions per minute almost any "drum" will now beat or strip out every grain from sheaves properly opened and "fed" to it. Much ingenuity having been applied to the shaping of new "beaters" (some of them, indeed, being no improvement upon the old square ones), and to the contrivance of a better "screen, or concave," we have now patent beaters, of different sorts, that may be said to perfectly extract corn from the ears without splitting or breaking it. They are adapted to damp, as well as dry stuff; and also save power, by being of a more or less wedge form, and so cleaving their way through the air, instead of driving it like a fan. At the Gloucester Meeting in 1853, and at Lincoln in 1854, about two-thirds of the combined-machines thrashed clean, or nearly so; and about the same number did their work without breaking the grain. At Carlisle, in 1855,

all the machines thrashed perfectly clean: two-thirds completely avoided splitting; and two other machines, out of the nine tested, were nearly as meritorious in this point.

As regards the state of the straw, at Gloucester two-thirds, and at Lincoln not half the machines, delivered the straw whole; and at Carlisle only two machines were considered perfect in this respect; while four others out of the nine nearly equalled them. But breaking the straw is a fault or an advantage, according to the purpose for which the straw is intended; and in districts where it cannot be sold, and is consumed as fodder or litter for cattle (and unless it is being thrashed for thatching), farmers prefer to have it well broken. Altogether, the performance of the strictly thrashing part of the machines left little to be desired in regard to the quality of the work; and in two years and a-half since that time, various improvements have been introduced. The time and power requisite for thrashing a given quantity of corn varied very much in different machines; and no doubt we shall find a great advance in these particulars, when the dynamometer is applied, between the engines and machines next July.

The processes of extracting the grain free from straws, ears, or chaff, delivering the clean straw by itself, and separating the chaff and pulse, colder or cavings, are not yet conducted in the most desirable manner. At Gloucester half the machines were thought to shake the straw perfectly clean, and one nearly so; at Lincoln three machines performed clean shaking, and seven more out of fourteen nearly equalled them; but at Carlisle there were only two out of nine machines which carried absolutely no grain over with their shakers, four others being only slightly defective; while there was plenty of room for improvement in the rest. So far good, as respects the two "perfect" shakers; but a quarter of an hour or twenty minutes' time of working is not long enough to detect the liability of the slats, screens, bars, or meshes of the shakers to collect choking straws, and gradually impede the passage of corn through them; for what are at first considered good shakers will sometimes be found to foul themselves in hour after hour of jumping underneath such stuff as straw and broken cavings of all imaginable lengths, bent in all possible forms, tossed in all postures, and traversing across the area of the shakers in every sort of direction. Freedom from liability to choke is a particular, however, in which many advances have lately been made. Another important consideration is, that this continuous clean-shaking shall be effected by simple mechanism, avoiding as far as possible all shock and unsteadiness to the machine framing, and excessive wear of brasses or working parts. Now, as the effectiveness of the process of shaking depends upon the most complete and repeated *tossing or striking*, as well as *thinly distributing*, or drawing out the bulk of straw, so that it may give the enclosed corn and chaff every chance of dropping out, some of the most thorough shakers are objectionable in their motion; while, on the other hand, some of the smoothest and easiest running imperfectly perform their work. How smooth and beautiful is the action of the rotary shaker, which dances the straw over a succession of revolving rollers armed with curved rakes or teeth! Yet, simple as are the means by which motion is communicated to these rollers, how many parts and small bearings there are! and the effectiveness of the work (at any rate at Carlisle) was far from perfect. But so important is the steadiness which it gives, the absence of shocks, and consequent smallness of wear and repairs, and freedom from gulling brasses and breaking shafts, that the principle is worthy of all attempts to increase the efficiency of its action on the straw. Box shakers appear to be the most general favourites with machine makers. The original parallel-motion spars thoroughly extracted the grain and chaff by their blows underneath the straw; but something more resembling a riddle or screen was required to prevent straws from dropping through lengthwise; and when boxes with wire meshes or perforated sheet-iron were found to catch and block up with straws, or else let them through, ingenuity devised slats of various forms to let through the corn, chaff, and pulse only. Then we had rocking-bars or slings at the outer end, thus relieving us from one of the crank-shafts, with all its wear and annoyances. However, if you diminish the tossing action of the boxes at one end, you must increase it at the other, either by greater speed or a further rise and fall, or else keep the straw longer upon the shakers in order to receive its due amount of blows. This latter plan is effected by prolonging the boxes beyond the vibrating bars; but in so holding back the straw, it is of course crowded closer together than if it had free passage over, and this principally at the point where it most of all needs opening, scattering, and dancing as lightly as possible—that is, just where the last few kernels are to be let fall out of the whole mass of straw. As a compromise between the parallel-motion, with crank-shaft at each end, and the vibrating at one end and rotating at the other, there is the plan of having half the boxes rock at one end and half rock at the other. Four boxes are the most common, but three have been tried, and we have seen two worked with admirable effect, though of course requiring a rapid speed. But the table shaker—that is, a screen all in one piece the whole breadth of the machine—is capable of turning out the best samples of long straw and cavings, as there are no apertures (as between boxes) where straws can get down, and nothing can pass except through the meshes. When constructed like a wire screen, however, straws will entangle and collect in it; and, if made with slats of wood or hoop-iron, the weight would become an obstacle to its jumping movement. The peculiar motion secured by the short slings on which it swings is precisely that well adapted for keeping the straw "lightened up" and loosely tossing, and as severely chucked and bounced at one end or one part of the shaker as it is at another. Now, cannot this be retained, and yet the shaker divided, so as to give a smooth and regular compensating movement, one half rising while the other is falling, and without additional slings (tiresome things) or additional complication? Suppose it made in two parts, not side by side, but one following the other, and each extending the same breadth as at present. Retain the present slings, one pair supporting the inner end of the first screen or table, and the other pair supporting the outer end of the second. Where the two shakers meet half-way, the first is to overlap the second, and both are to be hung upon cranks or eccentrics on a shaft placed across underneath, as for driving box-shakers. We should say that this arrangement would obviate the chief objections which the table shaker is now open to.

Separating corn from the chaff and cavings as they come from the thrashing machine must necessarily proceed on a different principle to the shaking of the straw in order to extract these products. Pulse, calder, cavings, chaffings, or whatever you call the short bits of straw and empty ears, can be divided from the grain and chaff by screening, sifting, or straining away the latter through a riddle; but as pieces of straw can penetrate endwise through an aperture large enough to pass chaff and corn, the aim must be to keep them horizontal, and avoid any tossing motion that might turn up ears or straw into an inclined or upright posi-

tion above the holes or meshes. The holes in a shaker may be small, yet the straws dropped through are many inches in length. In riddling, all these straws must be prevented passing through holes large enough for the corn; and this can be done only by causing them to travel across the screen without jumping and falling upon it as they do in a shaker. Revolving riddles, desirable as their even regular motion may be, cannot answer, unless, by means unseen at present, they are made to avoid the rolling and tumbling of the pulse upon the meshes or slat apertures; and contrivances for drawing or pushing the stuff across fixture riddles are also completely objectionable, from their heaping and gathering of the corn within lumps of the cavings, instead of thinning all out as much as possible, in order to facilitate the escape of grains and chaff. We cannot imagine anything for the purpose better than the horizontal jogging motion given to our present riddles, the riddle itself being slightly sloped so as to give every particle of stuff upon it a tendency to travel in one direction over its surface. If all the bits of straw, &c., were of one length, and all traversed the riddle in the same posture, lying either lengthwise or crosswise, it would be easy to shape slats or other divisions of the riddle into apertures that would be bridged and slipped over by the straws while admitting the corn and chaff to pass through. But the difficulty is, that the stuff lies in all directions, and is of innumerable sizes. The aim must therefore be to form the apertures of a shape—say round, square, or but slightly varying from these figures—so as to present equal impediments to the entrance of the straws or ears in every direction. A wire screen with square or hexagonal meshes, or sheet metal perforated, might answer the purpose very well for a short time—that is until it became clogged with caught and doubled straws—provided that no straws dipped and poked their ends beneath the wires, and so became gradually jogged underneath (that is, through) the riddle, instead of being conveyed over the top. Hence it is indispensable that sloping walls or partitions should be given to the apertures, at any rate on that side opposite to and meeting with the advance of the stuff, in order to hinder the passage of straws in a downward direction, and by their inclined surface raise up any dipping-ends on to the riddle again. This is a most important point in the riddling apparatus; and we advise purchasers of combined thrashing machines to be very particular in their choice; for when the riddles have any tendency to clog and block up, and continual attention is needful in clearing them, not only time is lost in frequent stoppages, but waste of corn is inevitable. Now, for passing off the straws endwise without any poking through, and at the same time for presenting apertures that no mass of chaff and corn can by any possibility choke up, we have the slat riddle, resembling a Venetian or louvre shutter, with the slats inclined say at 45 degrees. This form was originally intended also for having a blast underneath, which blowing up through the spaces, and meeting the corn and chaff, should separate the latter, as well as tend to lift and throw off the pulse above. But we do not approve of this principle, preferring (as we shall hereafter show) to separate the pulse by simple straining or sifting, and reserve the whole force of the blast for chaffing in a different manner. To prevent straws from dropping through transversely, wires were introduced, passing through holes pierced in the slats. To gain more aperture space, and obtain the raising action of the inclined slats on the opposite side of the spaces, angle-bars, with their edge uppermost, have been adopted; and another application of the principle of a sloping passage, or aperture, is seen in the riddle, made by boring round holes in a slab of hard wood, the holes slanting toward the blast, and widening downwards, so as not to choke. But, seeing that corn may possibly ride over this latter riddle upon the thick, though tortuous, interstices or partitions, although no pulse can penetrate through, and that straws may certainly drop between the angle-bars of the other riddle, or lodge across the wires between the slats of that first mentioned, our readers will be willing to receive our special approbation of a slat-riddle constructed as follows: The slats are to be of hard wood, half-inch stuff, before planed up, and say one and three-quarters inches deep; make them into a riddle, by letting their ends into a rectangular deal frame as wide as the machine will allow, and of sufficient length (to be noticed presently); the slats lying square across the frame, and inclined at an angle of about 45 degress; the distance apart, measuring from middle to middle of the (parallel) slats, is to be one and a-half inches at the inner end of the riddle, and gradually less till it is one and a-quarter inches at the outer end. Thus far we have simply a slat-riddle, made slightly to vary in the size of aperture, according to the bulk of stuff upon it at different parts, this being of course much less toward the outer end, when most of the corn and chaff has been parted with, than it is when first entering upon the riddle. But now fix wires (rather fine), lengthwise of the riddle, *upon the top of the slats*, crossing them at right-angles, fastening each wire to every slat by small wire staples; the wires to be one and a-quarter inches apart. This improved form of riddle, contrived by a mechanically-gifted farmer in Cambridgeshire, and since adopted by some great manufacturers (in one case strips of cane being substituted for the rusting wires and their tiresome staples) works to perfection, or comes very closely to it, whether for wheat, barley, oats, or peas. It is just possible that improvement may yet be made in avoiding still further the wear, or liability to damage, of a riddle rather tedious and expensive to make, and rendering it utterly impossible for short ears to drop through or catch under the wires at the corners. At present there are a few refractory bits that will make their way through, and require to be arrested by the smaller chaffing riddle to which the corn, &c., is next conveyed. And we may say here, that no riddle must ever be expected to be absolutely perfect in its action, and that therefore we ought not to trust to a single riddle, but employ a second (of smaller dimensions and diminished apertures) to rectify the occasional omissions of the first, besides the extra facility we may thus get for chaffing. We have alluded to the length of the riddle. It is a common error to have them much too short, and adapted pretty well perhaps to a steady and regular supply of stuff. But the supply is often very irregular, partly owing to sudden thrusting in of whole sheaves at once by the man feeding, partly to the gathering together of lumps of stuff (especially when damp) either upon the riddle or on the way to it; and we ought to provide for such extreme and extravagant amounts of stuff at any instant, if we would prevent waste and produce a pure sample. The farmer above-named has his riddle 4½ feet long, and would like to stretch it another foot at least, to make it equal to every emergency. His chaffing riddle, which stops the escaped odd pieces of pulse, is about 2 feet in length, made with slats at similar intervals to the other, only the wires are ¾ inch instead of 1¼ apart. Instead of crowding the stuff upon a restricted surface, let the principle be to spread and open it out as much as possible, by causing it to pass quickly over the riddle, and hence a considerable length is necessary in order to give it due time for letting fall the chaff and corn. Another point to be borne in mind is, that corn may ride upon or within a knot or braid of doubled or intertwining straws, and so be carried over with the cavings; there-

fore it is well to make the riddle in two or more successive steps, say of 1½ or 2 inches fall each, to break the masses of stuff, and present fresh surfaces, as it were, to the action of the riddle. Of course there must be a part of the riddle free from holes immediately under the fall, in order to receive the stuff and transmit it in its newly-arranged posture by horizontal sliding (produced by the jogging of the riddle) to the apertures further on, as any falling or jumping upon the riddle is likely to pop pieces of the cavings through.

BEANS FOR HUNTERS.

As regards the propriety of giving hunters beans with their oats, I do not consider they should be given indiscriminately to all horses in any way; and, to such horses as may require them, most certainly not *with* the oats. Most horses are excessively fond of the taste of beans; and thus habituating them to get this addition to their oats is very apt to make them refuse a feed without them. The way I recommend beans being given is with three or four double handfulls of chaff, and that wetted so as to hold any small particles of the bruised beans—for some such will always be found. The chaff prevents greedy feeders from swallowing the beans without proper mastication, and, being given as a distinct feed, does not habituate the horse to their taste with his oats. I hold it a bad plan to accustom a young healthy horse (reasonably worked) to beans. They may be necessary when the stomach becomes weakened and inert from age or over-work; but strong stimulants to the stomach, unless taken medicinally, are bad for biped or quadruped. The strong healthy young man of twenty may like his bottle of wine a day; so may the five-year-old horse his beans; but if accustomed to them, what will the one want at the age of fifty and the other at twelve? Beans might be necessary to hunters when they were at cover-side at daybreak, and probably did not get home till the same hour they now usually do when hunts meet at half-past ten or eleven. In such days a fox was hunted to death; now he is raced into. Horses' were then absolutely wearied out with a day's hunting; now they are blown and exhausted for the time being, but usually recover themselves ere they reach their homes. Horses refusing to feed after hunting was much more frequent (as I have heard) in those days than it is now. A pedestrian, after a long fatiguing match of sixty miles, walking against time or a competitor, will feel all his energies prostrate; nor can we wonder if his stomach becomes so also; but the runner of five miles, though more blown and exhausted than the other when he stops, recovers in a quarter of an hour, and is quite ready in half a one for whatever you may put before him. The case is somewhat parallel as regards horses, unless their powers have been so overtaxed as to produce absolute illness. Post-horses, in former days, consumed a good many beans. Well might horses want them, who frequently were taken two, sometimes three, journeys a day, of twenty miles each. Coach-horses wanted them, that in former days were driven sixteen or seventeen mile stages over roads like a ploughed field. In my remembrance, the old Bath and Bristol Blue drove such stages. Horses undergoing such labour required beans, as the coal-porter requires porter. Beans formerly were in common use in training stables. Those were the days when the trainer had the majority of his string (five, six-year-olds, and aged horses) running heats, and those often four miles. Here direct lasting stamina was wanted, and the old platers required their old hearts kept warm by stimulants; but the case is altered now. If a trainer has a four-year-old in his stable, he is "the old horse," and all the remainder of his lot are juveniles. Except in the case of a particular colt, a trainer would never dream of giving a two-year-old beans. He would hold them as the forerunners of colic, flatulency, constipation, and eventually fever. In former days grooms kept the bowels of horses more or less in a constant state of constipation, and judged the hardness of what a horse voided as a proof of *condition*. Formerly, even with a hunter, when he found occasion for evacuation necessary, he stopped short if permitted to do so. It was an effort he could hardly make while walking; it was all but a painful act. And this was held *condition*. It was a state in which, if I saw a horse of mine, I should immediately resort to the bran-bin.

Horses going a *journey* is now a thing spoken of as one of the strange acts performed by our ancestors and their horses. It was then ten miles and stop; ten miles again, the stoppage repeated; ten miles and a long stop to lunch or dinner; and then another ten miles brought horses and travellers to their resting-place for the night. Horses subjected to the profuse sweats a heavy carriage and execrable roads produced, and then perhaps saturated with rain, required their insides kept warm. But in these days a man owning horses and carriages takes them with him by the railroad, as naturally as he takes his hat and gloves when he intends walking. Well, these peripatetic stables, coach-houses, and sitting-rooms are extremely convenient. Gentlemen and ladies have not the trouble of rousing themselves to look at the country as they speed through it, not being enabled, if they wished it, to see much more of it in their carriage than their horses in theirs.

Mais à nos moutons. Bruised oats have been brought before the public eye with the paramount recommendation of *saving*—in short, the vendors of oat-bruisers understand their business, and they understand the reigning feeling of the public. They would rarely sell a machine if their recommendation only went to show that bruised oats were better for the animal than whole ones; but they show their use is better for the man, by stating that instead of giving five feeds of whole oats, bruise them and you need give but four. Now, if they could prove that the horse cut off with four feeds could actually do more work than the one with five, this would be a saving with a vengeance, in two ways. Why, in that case we should not find a carpenter or wheelwright unemployed; they would be all making oat bruisers to satisfy public demand. But it fortunately, or unfortunately, happens that bruised oats cannot effect miracles; for I roundly assert that four quarterns of bruised oats will *not* produce the same nutriment as five given whole; that is, if the five are properly given. I conceive that the best oat-bruiser ever invented is the grinders of the horse. Some say, and indeed with truth, that greedy horses will swallow much of their corn whole; granted, but mix a few handfuls of chaff with the oats, he cannot then swallow the mixture without thoroughly and properly masticating the compound. Greedy feeders will swallow bruised oats without masticating them, as fast or faster than whole ones. I should not give them a chance of doing either, or rather the chaff would not; for I hold it just as judicious an adjunct to bruised oats as to others. I have heard people say, "A horse swallowing bruised oats does not signify; he gets the benefit of the meal." I should beg to observe, in reply to such opinion, that a horse has not the reputed stomach of the ostrich; he cannot digest his shoes, nor can he oats *merely bruised*. If ground to meal it would be a different affair; but an oat does not remain long enough in the stomach of the horse to as it were dissolve, unless first formed into meal by the grinders of the animal, and properly saturated with saliva. I consider bruised oats, on the whole, as good enough, if you prevent waste, and bruise them at home; for I hold a sack of oats sent out for this purpose does not always come home as immaculate as it went out. It is surely enough, if bruised oats convey more nourishment than whole ones; but do not cheat your horse in measure, and thereby cheat yourself, by fancying all people say of bruised oats as fact. Let me feed my horse as I like on five quarterns of whole oats, and you give yours four quarterns of bruised ones, and give them both similar work; I think I can prophesy which at the end of three months will be in the best condition, to a far greater certainty than any man can prophesy who will win the Derby, much more the Leger. —HARRY HIEOVER, in *Field*.

WINFRITH FARMERS' CLUB.

INCIDENTAL DISCUSSION ON THE COMPARATIVE WEIGHT AND VALUE OF LARGE AND MODERATE-SIZED ROOTS.

The anniversary dinner of this Club was given on Wednesday evening, the 20th January, in the Black Bear Inn, at Wool, under the Presidency of Mr. J. A. Damen; Mr. T. H. Saunders occupied the vice-chair.

AWARD OF PRIZES.

The PRESIDENT had no doubt that the most interesting part of the evening's proceedings would consist in the Secretary's reading the award of prizes, which he, the President, had just broken open, as given under the hands and seals of the judges, Messrs. Henry Symonds and George Caines.

The SECRETARY accordingly read the awards. They were as follows:—

1. For the best ten acres of Swedes, the prize of £5, offered by J. B. Lawes, Esq., awarded to Mr. Charles Besant.
2. For the best root crop, upon one-sixth part of an acre of land, occupied by the competitor, the like prize of £5, offered by Messrs. Cardus and Dixon, awarded to Mr. J. Reader.
3. For the second-best ditto, ditto, ditto, awarded to Mr. T. H. Saunders.
4. For the best ten acres of turnips, the prize of £2, offered by Joseph Weld, Esq., of Lulworth, awarded to Mr. J. A. Damen.
5. For the best five acres of Swedes, another prize offered by Joseph Weld, Esq., awarded to Mr. J. Sly.*
6. For the best crop of *Mangel Wurzel*. No competition.
7. For the best five acres of ditto, prize awarded to Mr. J. Reader.
8. For the best acre of ditto, prize awarded to Mr. J. Sly.

These last-mentioned prizes were offered, we believe, by Mr. Robert Damen.

The Judges also highly commended Mr. Reader's Swedes, Mr. Clarke's Mangel Wurzel, Mr. Thomas Randall's Swedes, and Mr. Saunders' Mangel Wurzel.

The SECRETARY, in connection with these awards, read over the printed rules of competition adopted by the society, which appeared to have been acted upon by the judges, with exception of that part of them which required the prices and quantities of the manures used to be stated, but this it appeared had not lately been observed.

Mr. ROBERT DAMEN proposed the healths of the successful competitors, which he had much pleasure in doing, and, at the same time, in congratulating them on their success. Those who had not succeeded in this instance would, he hoped, not be dejected. That the rule requiring the manure which had been used to be stated had not been acted up to, he thought a pity, for it seemed to him that it would be interesting to know how those great and weighty roots which had gained the prize had been grown—a mere estimate might have been given of so interesting a fact (Hear, hear). He begged leave to propose "The Successful Competitors." All the honours.

HOW TO GROW HUGE ROOTS.

Mr. J. READER, in returning thanks, said that he had expected that Mr. C. Besant, who had gained the first prize, would have responded in the first place; but as the second prize was very nearly equal to the first (laughter, "They are both of the same amount"), he must say that he felt pleased at finding himself a successful competitor, when he had to meet such competitors as their friend the vice-chairman, who was almost the champion of Dorsetshire—for, having carried off Mr. Williams' prize some years ago, he might be considered as having become some years ago the Champion of the County; and he was in fact acknowledged to be as as good a farmer as any in the county. And not only was he there, but there was, moreover, another person who was present to compete with (a laugh), who, if he had not the deepest land, had as essential a thing; he had Mr. Weld's pocket to go to, and also those piggeries and feeding-stalls yielding that first-rate manure which was alike essential to good farming and essential to the growing of roots. He felt convinced he should never have grown the roots he had done, had he not manured them with first-rate farm-yard manure as well as with artificials. He had manured with the dung of fattened beasts, fed on corn and afterwards with artificials. In the first place, he had given from 30 to 40 tons of farm-yard manure per acre, and good too; and then, from a-half to three-quarters of a hundred weight of guano, and the same quantity of superphosphate. The greater part of his roots had been thus manured; but seven baulks had been manured with Messrs. Spooner and Bayley's mangel manure (applause), which he at first thought to be done at a dear rate, for he did not expect the same weight on those baulks, although quite the same quantity of manure had been used on them. In this expectation, however, he had been deceived. He had thought that the guano and superphosphate would have beaten —but it was not so. Where he had tried bones on these baulks he did not expect the same benefit from them as upon the hills; but when he got farther into the upper part of his farm he used a quarter of bones per acre; and, on the other hand, he had now tried guano and superphosphate mixed together, and had tried the mangel manure against it. He had forgot to tell them that he had used also of salt about 6 tons on 16 acres. So satisfied was he of the efficacy of salt as a manure for mangel, that he should continue to use it for years to come: he did not think that it benefited Swedes; but as for mangel he hoped to use it, as he had said, for years to come. [Mr. Robert Damen: "Have you weighed any part of your roots?"] He had not weighed the whole of his produce, but he had found that where the mangel manure had been used he had obtained 40 tons 2 cwt. per acre; where superphosphate, 45 tons 2 or 3 cwt. per acre; and on the upper part of the field 49 tons per acre. These facts he had ascertained by weighing in each instance a square rod, topped and tailed, clean.

COMPARATIVE VALUE OF LARGE AND MODERATE-SIZED ROOTS.

Mr. BONE, of Avon, said he attended there that evening as a matter almost of course, because he always attended the anniversary of the Winfrith Farmers' Club, and not being at that moment in the best of health, he ought rather to have excused himself, could he have done so with any sort of grace; but the knowledge that both Mr. Spooner and Mr. Blundell were suffering from severe illness, had weighed with him as an additional reason why the members of local farmers' clubs in the neighbourhood should attend there, in order to keep up the intercommunication which they had from time to time held with that club. Such were the reasons that had induced him more particularly to attend on that occasion. He was extremely well pleased to find the Club going on, doing good, and progressing. The utility of such clubs was beginning to be every year more and more discerned. Every year the necessity for discussion was coming to be felt more than before agriculture had taken up that prominent position it had done since former years. As agriculture ebbed and flowed, discussions ought to be taken over and over again; papers ought to be re-read and discussed anew, in order that they might revise and alter conclusions which they had come to on previous occasions. He need not illustrate this from any other matter in agriculture beyond root crops. They all found that the turnip crop was no longer to be depended upon; they also found mangel wurzel becoming of the greatest use in agricul-

* Mr. Sly has since favoured us with the following note:—"Manure used for Swedes per acre—2 loads of a mixture of pig-dung and ashes, 2 cwt. of Spooner and Bailey's superphosphate, and one-sack of half-inch bones. For mangel baulked—15 load (put) of mixed horse, cow, and pig dung, 2½ cwt. of salt, 2½ cwt. of Spooner and Bailey's mangel manure, sown by hand on the dung in the baulks before covering up; alongside of this used 2 cwt. of the best Peruvian guano per acre. When the roots were taken up we could not tell any difference, therefore I am now convinced that we can do much better without using any of the *costly* foreign stuff, until the price comes to be equal with our own *country's manufacture*, particularly if our landlords will only lend us a hand to erect sheds, not costly ones, to graze different sorts of stock in."

ture; and they also found that great stress was laid by agriculturists upon growing the largest possible roots. This he was inclined to think a great mistake. He had just read a very able paper by Dr. Wolf, the principal of an agricultural college in Germany, in which he stated that on their experimental farm, there had been a piece of newly broken-up land planted with the sugar beet, which was used for the purposes of distillation; and it had produced a magnificent crop of large, beautiful, and luxuriant roots; but after they had been grown they had been found to be quite useless, for the sugar manufacturers would not take them at all. Now, it was a well-known fact that sugar produced fat; yet it was not that principle in the feeding materials of roots, or any other thing, but nitrogen, that possessed the greatest feeding value. Well, as regards nitrogen, Dr. Voelcker had performed a recent experiment on fusty clover hay, and found that it showed more nitrogen when fusty than sweet hay did. No practical man would believe this; at least they all knew that sweet hay was better than fusty (a laugh); they were not all scientific men, but scientific men might meet with practical men at the clubs, and find that they had arrived at conclusions such as these. He trusted his friend Mr. Reader's large roots would not turn out the same as Dr. Wolf's; it would be a bad affair for him after the liberal allowance he had given them, and it was a question whether they ought not to keep to such an amount of roots per square acre as not to produce them of an over large size. They were aware that large roots did not possess that amount of nutrition that small roots did. Mangel wurzels of over 10 lbs. weight when cut open were generally found to be hollow and insipid. If that were the case it was impossible they could contain the same amount of nutrition. In conclusion he expressed himself pleased and proud to meet them all, and to see the Club flourishing, and he hoped that they would all again have the pleasure of meeting together and learning that the Club derived benefit from its intercommunication with others.

LANDLORD AND TENANT.

Mr. T. H. SAUNDERS, in responding to a call made upon him, expressed himself extremely obliged to his excellent friend Mr. Randall, and to the company. One thing Mr. Randall said with especial truth, and that was, that whenever an experiment had been made by him, he had always given the advantage of it to the club. He had told them in what he had failed, and he believed he had told them too in what he had succeeded. He had been happy and proud to belong to the club ever since it had been established in 1846, and he hoped that it might continue to flourish for many a year to come. Mr. Bone had alluded to the benefits introduced by the club into the neighbourhood, to which it had been of the greatest advantage; for if they took the line of hills that belonged to the district, no man could fancy the extent of that advantage unless he had previously seen them in their original state. It was not good for a farmers' club if every man in it did not speak out whatever he knew. It did no good to come there and say nothing. Yet a great many members came there and never spoke out at all. Nor was there any good in adhering merely to one side of a question. Agriculture could go much further than it had yet gone. He thought that it might assist the landlord as well as the tenant. Mr. Calcraft had alluded to the propriety of his admission to the club, because Mr. Calcraft was a landowner, and at first sight the club appeared to be merely a farmers' club; but what did that mean? It meant a club devoted to the benefit of agriculture at large—to the benefit of the landlord, the farmer, and the labourer, all of those three interests being bound up in one. They should be happy, therefore, to see the landlord amongst them, if he came to meet the tenantry, and to hear their discussions month after month. The tenant could not go on single-handed; and if the landlord came in that spirit, they would be happy to see him, that he might see in their discussions what it was that they really required; but if he came not in that spirit, he ought to be expelled the club. If he came to them as Mr. Calcraft had come that night—let him come. If the landlord and the tenant went hand-in-hand together, England might defy the world. He was happy to see Mr. Calcraft becoming a member of the club, and hoped he would continue to be one for some time to come. The advantages of such clubs were too numerous to relate; but in a few words he had given the heads of his opinion regarding them; and he hoped that he had not said anything that might be disagreeable to anyone on the subject of landlords entering the club. His (Mr. Saunders's) was only one opinion; everyone had a right to his own opinion. If the landlord came there to see what was wanted, he would find that they wanted only a fair day's pay for a fair day's work, that they only wanted interest upon their capital; but if he did not come, he might think that the results of farming were double what they really were. He would find that the farmer did not get more money than was his due. Look at the manure bills. Good crops were not all profit: but, if the landlord was willing to spend a shilling, the farmer was willing to spend a shilling too. He had omitted to say that he hoped the young members of the club would, more generally than they did, take up subjects and introduce them for discussion, and thus the opportunity would be given to the elder members of setting them right. He thought that in this view of the matter the clubs were good schools for young men.

MANURING ROOTS.

Mr. FOWLER said he would observe in regard to the subject of their discussion that evening, but without attempting to detract from the course that had been pursued by Mr. Reader, in using so enormous a quantity of manure for his roots, that he coincided with his friend Mr. Bone. They might draw an inference from what occurred in managing grass lands; when they placed manure upon grass lands the stock did not thrive so well. On a field of his own, some large swedes were grown on a spot where there had been a dunghil; and he had been curious to ascertain whether a solid inch cut from these large swedes weighed as much as a solid inch from the ordinary-sized swedes in other parts of the field? He tried this, and found that the solid inch from the ordinary swede considerably outweighed the other: he did not go to grains and minutiæ, but the fact was so. He did not wish to raise a discussion on the point of Mr. Reader's largely manuring; but he agreed with his friend, Mr. Bone, that they might gather some practical information by considering the difference in value betwixt large and ordinary-sized roots.

Mr. READER said: With regard to the size of roots alluded to by Mr. Bone, he (Mr. Reader) never meant to compare a large root grown, say in a bog, with a root of the same size grown on strong land; for he was convinced that, if they grew large roots on bog-land, they would not prove of equal quality with roots grown on stronger land. But, still, they were not very liable to err in that way. They rather erred, he was afraid, the other way; and, for one mistake they made in growing roots large, they made fifteen in growing them too small. The largest he had raised this season had been given to his running store pigs, and that was a pretty good test of their feeding qualities: he assured them that these pigs had had nothing else this fall (Hear, hear), and that the sows in farrow had had nothing but the trimmings of the roots. He was glad to say that there were not a few of them that were not hollow; in corroboration of which he should refer them to Mr. Watt, who had cut them. A square inch, cut from a root which had grown in a "mixen," was hardly a fairly sample of a field; for it was seldom that they made a "mixen" all over a field. But, no doubt, were they to take a square inch from a root grown on strong land, and another from a root grown on boggy land, they would find the square inch grown on the strong land considerably the heavier. If, however, the error alluded to did occur, it was seldom on the strong land of their hills, where there was acid enough to dissolve the bones, and not a particle remained in a short time; for the land ate all up.

Mr. DARBY, of Lytchett, in an able speech in support of Mr. Bone's view, said that it was better to grow medium-sized than large roots, which, before they were pulled, began to decay; and related an experiment in which he had succeeded in rendering fusty hay edible by steaming alone, without the aid of salt.

Mr. RANDALL took up the point, into which he said the question raised by Mr. Bone resolved itself: whether turnips had better be sown in 18-inch drills 9 or 10 inches apart, or in 2-feet drills 14 or 15 inches apart? It was, in his opinion, the 18-inch drill, yielding a moderate-sized turnip, that gave the most crop and the best feed for stock,

He also alluded to a peculiarity of the club. He had scarcely ever known one member of the club carry off the best prize for two years running, the successful candidate being almost always sure to be beaten next year.

Mr. CLARKE only rose on being loudly called for, and gave the following very interesting account of his produce. He had grown upwards of twenty acres of roots, not very large, but, as Mr. Symonds, who was the judge, could tell them, tolerably good. His system was a four-course one. His first sowing had been on the 10th of May, his next 14th May: to the baulked-up land he had applied 12 cart-loads of dung, prepared in the field, and spread upon the baulks 3 cwt. superphosphate and 1 sack of bones, and it had been his intention to use 1 cwt. of guano when using the horse-hoe; but he had not had an opportunity of using the guano, the season being so dry that it seemed like throwing it away. Taking up 4 square rods of mangel, he had honestly divested them of all tops and roots, put them on the weighing-machine, and, although he had not been asked the weight, he should state it: it was 39 tons 18 cwt. The roots were regular, uniform, and, notwithstanding that the season had been so dry that at one time there was scarcely a leaf to be seen on them that had not withered away, they had turned out a very good crop, and would keep his stock for the winter.

The conviviality and discussion were kept up till 10 P.M., when the company dispersed.

HEXHAM FARMERS' CLUB.

The annual meeting was held at The Grey Bull, Hexham, on the 12th of January. The following were appointed the officers of the society for the ensuing year: Secretary, Mr. Lee; President, John Grey, Esq.; Vice-Presidents, W. B. Beaumont, Esq., M.P., John Errington, Esq., Mr. Nicholson, and Mr. Brown: Committee—Messrs. William Trotter, Goodrick, Dodds, Harle, M. Stephenson, Cook, and R. E. Ridley.

At half-past two about seventy of the members sat down to dinner.

The chair was occupied by John Grey, Esq., Dilston House.

The CHAIRMAN gave in succession the loyal toasts. He then called upon the secretary to read the following

"REPORT.

"In presenting the twelfth annual report the committee have again the satisfaction of stating that the society continues to increase, and has now 164 members, with a balance of £35 1s. 11d. in the hands of the treasurer. The committee have to express their thanks to those members who have so ably introduced subjects for discussion. The monthly meetings during the past year have been well attended, at which discussions took place on the following subjects:—Jan. 13, 'The landlord's interest in a lease, and its tendency to promote good cultivation;' introduced by John Grey, Esq., Dilston. February 10, 'On farm accounts;' introduced by Mr. J. Lee. March 10, 'On the prevention of diseases among farm stock;' introduced by Mr. Woomack, Shildon Hill. April 13, 'On hay-making;' introduced by Mr. William Trotter, East Acomb. Oct. 13, 'On the prevention of diseases among cattle and sheep;' introduced by Mr. Woomack, Shildon Hill. Nov. 17, 'On the selection of agricultural seeds;' introduced by Mr. C. Reid, Humshaugh. Dec. 8, 'On harvesting corn, and the advantages of mowing over reaping;' introduced by Mr. Harley, Mill Hills. The premiums given by the club for the different operations in harvest-work excited great competition; there having been 44 entries for mowing, 10 for binding and stooking, 21 for taking up and sheaving corn after the mowers (by women), nearly the whole of which work was done in a most satisfactory manner. Only two reaping machines were brought into operation; that of Burgess and Key attracted great attention, and did its work remarkably well. The committee beg to suggest that premiums be again offered for the best mowing, taking up corn, &c."

On the motion of Mr. STEPHENSON, the report was adopted.

ON THE DESTRUCTION OF WEEDS.

The CHAIRMAN then said it was now his duty to bring before them the subject of the day's discussion, and he begged their forbearance. That he had not put pen to paper on this subject, and that he had been able very little, indeed, to consider in what manner it ought to be brought forward, he begged them to believe was not out of any disrespect to the club, or from any want of cordial feeling towards its rules, but merely that his time had been of late very constantly and very anxiously exercised; so that he had come there with the mere purpose of opening to them a subject which he believed was so familiar to them all as to be rather one which must be dealt with in conversational discussion than in the manner of any lengthened lecture. It was not one of those subjects which was very imposing, as embracing any particular or high principle connected with the legal tenure of land, or with the rights of landlord and tenant. It was, however, notwithstanding this, one of the very greatest importance in all the round of agricultural practice. That any man of common sense should expend money in purchasing and applying manure to his land for the purpose of growing weeds, was too great an absurdity to be for one moment entertained; and they knew that the perfection of cultivation was to have the land they were occupying in such a condition as to grow merely that crop which they intended to produce, and to grow it to the greatest perfection. It would be unreasonable and absurd in any man to think he would employ cultivation and manure upon a field which he had sown with wheat, and then to let it expend one-half of its fertility in producing docks and thistles. It would be equally absurd for any farmer to give such encouragement to the noxious weeds which were grown as if he were to sow them for the purpose of rearing them. It happened to him about two years ago—at least the last time he was requested to take any part in the proceedings of the Royal Agricultural Society of Ireland—to have remarked, in passing through that country, amidst many luxurious crops, a very great proportion of weeds, of course taking away from the bulk of the crop in the first place, and considerably injuring the sample of corn in the other. He was called upon on that occasion, in the presence of the Lord Lieutenant and many of the aristocracy, to give an address to the people of that country upon some subject which he thought might be beneficial. The show of that day was a very magnificent one, and he might have taken a laudatory strain, and have praised the people of Ireland for the great exertions they were making, and the great success they had achieved in the breeding of stock; but he took that very subject which happened to be the subject of their discussion that day—the absurdity of allowing their land to be drained by noxious weeds; and in consequence of that address, some discussion had been going on in that country lately, and a paper had been sent to him, from which he read an extract. Now, if there be any truth in this (he continued), that by a clean system of farming in Ireland, one-fourth, or even much less than that, of the produce would be increased, how well must it be worth the while of the cultivator of the land to do all he could for the destruction of the weeds! It was very true that the man who might expend something in cleansing his own field of weeds was not very much advantaged if his neighbours all around him allowed theirs to go to seed, and even if the road-sides—as he was sorry to say was too often the case in this country—were allowed to grow thistles and docks, the seeds of which were spread about by winds, and carried down ditches by floods, and so deposited on the lands below. There were various kinds of weeds which required very different treatment; some, such as the dock, thistle, and others, planted their roots in the ground, and could not very well be extirpated except at great pains in extracting them individually as they grow. This was an expensive and slow process, yet it was well worth their while to do as much in this line as they could. There were other weeds which

they had most to contend with, and the process of fallowing well, and careful hoeing, and clearing the drills of the growing crops, was perhaps the only true mode of overcoming these their annual weeds, such as wild mustard and chickweed, and worst of all, that enemy to cultivation, couch grass. The first step, as he conceived, in obtaining an entire clearance of weeds of this description, is to have the land properly drained; for draining was the great cardinal virtue of agricultural progress. If they happened to be going over a farm, as was often his case, and saw a spot in a field more brown and less fertile and more productive of weeds and couch than another, they were told, "That is a wet spot: we can't get it well worked." But then there was such a thing as draining to extract the wet; and in other cases they found that if a portion of a farm was very foul, the excuse for this was, "It was a wet summer when it was last in fallow, and we could not get it cleaned." There was great truth and reason in these things; but the only way to overcome them was to take the wet out of the soil and to make it uniform in its surface, so that the same manner of work and the same kind of cropping will be equally suited to the whole of a field. These were subjects that he hardly need detail to a company like that, because they were matters of practical knowledge that were before them, and they were subjects of everyday experience; at the same time, it was perfectly allowable, when they were met together to endeavour to improve the management of a district and its farming and general produce, that these things should be taken under their very serious consideration. Another subject—that of fallowing, which was one of the greatest possible importance—had lately been very much discussed, and great recommendation had been given to autumn fallowing. It had been said by very good judges that if they wished them to judge of tenantry let them look over their farms in autumn, and that the best tenant would be seen by the cleanness and style in which the fallowing had been done; he did not mean bare fallow alone, but a fallow which consisted of green crops, put up in such a way that horse hoes, hand hoes, and all the implements used for such purposes, could be employed. Last autumn gave a good opportunity, which he was happy to see made available by many farmers, for cleaning the land and advancing the work for the ensuing spring. The spring might not happen to be so favourable as was the autumn. He had, in his small way—it was too small for him to presume to set himself up as an example of good farming—but still, if there was safety, economy, and advantage upon a small scale, that advantage and economy must tell in the same proportion upon a larger scale. It happened to him that he had only a small patch of ground, in which was about ten acres of turnips each year, and he had only one pair of horses to do that, carry his coal, and everything he wanted. It therefore required him to economise the labour; some part of his land was rather strong and heavy, not very congenial for turnip soil, although he had a portion of that too, though if it were worked and laid flat in the common way in the spring, and then should get a very heavy fall of rain, it would run together in such a way that his poor pair of horses could never again overcome it, or put it into such a condition as they all knew was necessary for the production of a turnip crop, because the small seed of the turnip would not vegetate, and could not grow well if the soil into which it was put was not equally minute in its particles, and as near in a state of powder as might be; but if land with a little dampness or tenacity in it requires to be worked up late in the season, he needn't tell them, practical farmers, what a difficulty there was in overcoming that loss of time, and in getting a crop of turnips. The plan he had followed—and he hoped they would not think it presumptuous in him to name it to them, and they could follow it or not—was this: He began, as soon as the crop was stored, or as soon as possible, with skim-ploughing the surface, harrowing and raking it together, and carting it off, putting it into the fold-yard to be the nucleus of the manure heap for next year. He then gave the land a deep ploughing, harrowed it, and put it into drills ready for the manure. When the manure was put in he reversed the drills, and so it lay, and nearly one-half of his turnip land was now in that condition, drilled, manured, and exposed to all the changes of the atmosphere during the winter. It came to be found in a mellow condition in the spring, and the turnips were sown upon this; whereas, as he told them before, if the land required to be worked up in a damp state, he could not make turnips of it at all, and for the few years he had practised this, he had never failed in finding that the turnips sown upon that portion of the land came quickest into leaf, and overcame in the shortest period that great difficulty of rearing a good crop of turnips—that of coming quickly to the hoe. He ascribed it to this reason: the land upon the top of the drill was exceedingly mellow and fine; the manure had been undergoing—not the fermentation which it got when thrown into great heaps, where it dispersed its ammonia into the air, and wasted much of its best virtues—but it underwent the slow and quiet process of fermentation throughout the winter, covered up with soil; and they found in the spring all the soil contiguous to the manure in a soft and brown condition, having inhaled much of the virtue which the manure had given off. It was generally the practice to use some kind of extraneous matter with that from the fold-yard; the manner of doing this was only to run the drills over with a light harrow of any kind, but more especially with those little concave harrows of which they had seen specimens—one horse drawing two, and doing two rows at one time. This puts the top of the drill a little on the bite, and the guano, bone-dust, or other manure sown was set up to a top of the drill by passing a double mould-board plough through it. The seed was sown upon this portion of the soil; and he believed Mr. Lee and other neighbours that might have seen his process would bear him out in saying that the produce had not only been very quick, but very good. He thought this a matter important to be considered, because the quantity of turnip land in this and other countries was much increased, and naturally so, from the introduction of extraneous and foreign manures, which, together with draining, allowed farmers to go over a much larger surface. If, then, by such a process as this there was an economy of labour, and if that economy was at the same time connected with success in the production of a good crop, it could not but be a subject worthy of their consideration. He invited discussion, and said he should be very glad to answer any question relative to the subject. On that and all occasions he should be most happy to do his humble endeavours to promote the welfare and advancement of the agriculture of Tyneside.

Mr. DODDS had always followed the practice recommended by the Chairman, of getting his fallow clean in the autumn; and the mode he took to do so was very simple. If the land was light, he simply put the grubbers through it, and commenced harrowing and hoeing, and if necessary raking. If the land was at all stiff, he took an ordinary plough—several had been invented, but they only added a great many implements to the farmer's stock, and were expensive to obtain—with a few broad shares, and it could be used with or without the mould-board. He got out the twitch with great facility by simply cutting the roots with the mould-board of the plough; but a little bit of sheet-iron instead of the mould-board would make the twitch come out much more readily than if turned over altogether on its back, or left lying. After going over it once with grubbers and hoes and rakes he grubbed it again. The land cleaned much more easily in autumn than if the tools were left to ramify during the winter. If they set to work immediately after harvest, especially on dry lands, to get out the twitch, the work would be greatly lightened in spring.

Mr. LORAINE wished to impress the importance not only of destroying the weeds, but of destroying them at the proper time. The greatest enemy to the farmer was the thistle—a weed whose seeds blew far and wide caused an immense expense, and caused the corn to reap badly. When thistles were not cut till they were a certain height, they ripened, and the seeds were blown in all directions. He asked Mr. Grey to suggest the right time for destroying thistles.

Mr. BIRD said he had about seventy acres of land, ten of which were in turnips. The great seminarium of twitch grass was the seeds. On dry lands he pushed on his seeds as well as he could, with a little assistance from nitrate of soda; he cut them before they were well seeded, and then he afterwards got a crop of turnips. Then came barley and seeds, and he took care to cut them before they were shedding their seeds, and in time also to get a very good crop of turnips. Then he came with barley afterwards, and sent his work-people to see if any weeds were left; they found very few left; and after he had had four years' experience of this practice, he had no necessity to gather a weed, because the land was clean. A farmer, having a sixteen-years' lease, could save the expense four times over before the lease was out.

Mr. LEE found no difficulty in letting grass remain two

years and having the land clean. He did not find "quickens" so great an enemy as wild oats and mustard. In a crop of barley there was a difference of four bolls an acre where mustard grew and where it did not. A few years ago he had a loss of £3 an acre where wild oats and mustard grew in a field of fifteen acres of wheat. Weeds were a great nuisance, and took a great deal of nourishment from the turnips.

Mr. COOK showed that the practice in the valley of the Tyne would not work well on the hills.

Mr. SMITH had tried for a good many years a system of laying manure in the back end of the year, and drilling up the land; he found it entirely fail; but his land was on the hill-side, and the storms broke up the furrows, and washed the best soil to the bottom of the hill. He quite agreed with Mr. Grey, that the manure should be laid on fresh.

The CHAIRMAN believed there was a time when they might destroy thistles, but it was neither at their earliest growth nor when too ripe, but when the stem near the ground was so far matured as to be a little hollowed, so that the first rain fell into it and rolled it down. He believed there were no means of eradicating wild oats or mustard but by first allowing them to vegetate and then pulling them out. Wild oats might be one hundred years in the land, and still vegetate when brought to a certain distance of the surface.

LABOURERS' REGISTRATION OFFICES *versus* STATUTE FAIRS.

In the agricultural discussions of the past year, a paper by Mr. John Marshall, of Riseholme, Lincolnshire, on the maintenance of farm-servants, occupies deservedly a very prominent position. Himself a practical man, residing in one of the best-cultivated districts of the kingdom, Mr. Marshall spoke more especially to his own experience. This would appear, indeed, to have had only one drawback—it was almost too good. The hinds of Lincolnshire were certainly the happiest race of peasantry under the sun, while rumour went on to say they were also the best servants. They really showed some return when well cared for. In detailing his practice Mr. Marshall went on to say how he paid his men, and where in accordance with the custom of the country he obtained them. He referred of course to the district Statute or Hiring Fairs. He stated at what times his people were permitted to attend them, for the purpose of finding fresh places. And he did all this without in any way denouncing the means which lead to such an end. On the contrary, it would come rather as part of a system, which as a whole was proved to work remarkably well. In the autumn of this same year the reverend Mr. James read another paper on much the same subject, and at the same place—the Central Farmers' Club. In the course of this, the latter took occasion to directly denounce these Statute Fairs as "the labourer's curse":—"Let us consider that dangerous age when our lads think themselves their own masters and beyond control; when they leave the roof of their parents, or first employers, and sauntering forth perhaps to a statute fair (which is, I maintain, the labourer's curse). let themselves out for a mere twelvemonth to any master who may engage them; at the expiration of that time setting off again to meet with another master, a new home, and new companions, hardened perhaps in crime and villany, considering themselves mere migratory beings, with now little or no religious character, no sense of Sabbath duties or Sabbath observance, and nondescript in feelings, habits, and views, instead of the upright, handy, diligent, skilful, trustworthy servants of which we talk, but take so little pains to produce." Now there is palpably a great deal of this in direct opposition to what Mr. Marshall had already told us. He showed us that lads and men hired at statutes might be, and were, steady and diligent; that they did attend church; and that, perhaps, in no other way were they so certain of becoming skilful and trustworthy labourers.

It is only right to say, however, that Mr. James, as a clergyman, by no means stands alone here. Indeed, the two classes seem very much inclined to join issue on the subject. The clergy say these hiring fairs are most terrible evils, conducive to all kinds of vice, and that they ought accordingly to be done away with The farmers, on the other hand, see no great harm in them—and maintain, moreover, that it would be difficult and inconvenient to do without them. This very argument is now being discussed in Mr. Marshall's own county. At the instance of the clergy, a meeting has been held within these few weeks, in Lincoln, with the object of establishing a "Servants' General Registration Society," that is to say, a register-office which shall embrace equally in its operations domestic servants and farm-labourers. The Bishop of Lincoln opened the proceedings. After speaking to the defective education of the poorer classes, his Lordship went on to say, "There is another disadvantage to which our farm-labourers are subject—the early age at which they leave home. I do not mean simply the early period at which they are sent out to work; but the youthful age at which they are put out to service at a part of the county very far from their home, so that long before their character is formed they are removed from the reach of those influences by which character ought to be formed—not only from their parents, but from those to whom they have been taught to look up—and they are often thrown in contact with bad characters, whose influence begins to act upon them. Added to this is the great disadvantage, as I must think it, though it is to a great extent perhaps inevitable, of the annual changing of situations. This, I am aware, cannot, to any great degree, be obviated, because as the boy's or girl's labour becomes of greater worth in proportion as they grow older, and as their masters or mistresses may not require just that kind of labour, they must seek to better themselves elsewhere. But I have reason to believe that the almost universal practice of these changes arises in a great degree from the custom of the country, and from the will of the children themselves, who seem to consider it quite right that every year they should remove to a different situation. However this may be, I believe that this practice, conjoined with that of not requiring character at these hirings, is the cause of an almost incalculable evil. It results from this—and I beg you, gentlemen, to mark my words—it results from this, that a good character is of little or no value to a farm servant. We know that in the case of ordinary domestic servants, their good character is their capital. It is that on which their success in life depends. They know that if they lose it they must be content, perhaps for the whole remainder of their lives, to put up with worse situations, both in point of comfort and remuneration. But our farm servants are without those motives. Hired without any inquiry into their character, they feel that it is of no consequence to them to acquire a good character in their present situation, because they leave it at the end of the year, and it is of no greater advantage to them in their future situation, because in all probability it will never be asked for.

I have to add to this the subject which is more immediately before us at the present meeting—the evils of statute-hirings—or, it would be more correct to say, the evils of the statutes at which our farm servants are hired; for there could be no objection, of course, to hiring at statutes were it not for the sights and scenes to which these young people are exposed on such occasions. Those you know better than I do; I will only call to your mind that at the annual statute these young men and women—or rather, boys and girls—have their one great holiday in the year, when, relieved from their labour of the past year, they are excited and more liable to impressions from without than at any other time; that they meet together in crowds in one of the towns, without the eye of their parents or friends upon them, surrounded with temptations which the publicans and others put in their way, and without any check upon them, or very little, for the fear of losing their character, or the wish to maintain one they have already obtained. You are well aware that it is scarcely possible to pass through a town, or a road in the neighbourhood of a town where these statutes are going on, without seeing enough to show how much mischief and immorality they must occasion; and I believe there is many a man and woman who has had to rue to the end of their lives the evil which they have learned there." The Bishop concluded by thus summing up the assumed advantages of the new plan: "It gives a value to character (and that is a very great point); it renders unnecessary, at any rate, the hiring at statutes; and it encourages—indirectly certainly, but still it does encourage—the servants to remain more than one year in the same situation."

The next speaker was one of the best farmers in the county, the well-known Mr. William Torr of Aylesby. It will be impossible for us to follow him throughout the whole of his very telling address, but we may give the chief points in answer to what had already been advanced:—"The hiring of farm servants was a different thing to the hiring of domestic servants. In the first place it was positively essential that the farmer should see the men he wanted to hire. In order to do this, there could not be a better arrangement than having a day when both classes should meet and have a choice. The Bishop said that characters were not reckoned of any consequence on such occasions; but he (Mr. Torr) believed that characters were generally inquired about in the case of the better class of servants. He was free, however, to admit that characters had not been sufficiently attended to, but that was not the fault of the statutes; it was the fault of the masters, who did not attend the statutes, and who were consequently not there to speak to the character of the servant who was looking out for another place. Now, supposing registration offices were established throughout the county (though he did not believe them to be practicable), how would a farmer be able to make his selection? Say there were two names down—one William Smith, who had lived 19 years with Mr. Brooks, and the other James Brown, who had lived 19 years with Mr. Iles, both wanting situations as waggoners, and having good characters. He (Mr. Torr), wanting a waggoner, might pitch upon William Smith; and when he had an interview with him might find that he was knock-kneed, very weak in the back, with an excellent character, but not an atom of use as a waggoner, while he had lost the chance of obtaining the other man Brown, who was a strong active fellow, and just the man he wanted. Such a system would never do. But in the statute you could pick your man out. It might be called a white slave market; but he maintained that it was the best way of doing it. A man had a right to make the best bargain he could—the master in getting his labourer, and the labourer in disposing of his services; and both of them had the best chance in these statutes, where a large number of them met for the purpose. He thought that the statutes had been overtaxed with an enormity of crime. He was free to admit the immorality that prevailed on such occasions, but he meant to say that whenever her Majesty's subjects met together in large crowds, there was the same sort of thing—whether it was a statute, or country fair, or an excusion train (which he believed presented the worst scene of all), or at Epsom or Doncaster Races."

Then, again, as to what certainly looks at first like a weak place in the system, Mr. Torr explained that—"The changing of servants was a matter of necessity rather than choice on the part of both masters and servants. He found, as a master, that if he hired a boy to mind a pair of horses, and kept him a second year, when he would have to mind four horses, he was not as well served; so he gave him a character, and the boy got another place, and the change was better for both parties. He (Mr. Torr) would be sorry to do anything that would tend to lower the agricultural status of this county, believing that they had an excellent lot of labourers now, and that registration offices would by no means improve them. He had the lowest possible opinion of the existing registration offices." Mr. Skipworth had also "a very poor opinion of registration. It would be impossible for a man to hire all his labourers in that way: he would be travelling two months in the year to select his servants. As to character, when a youth conducted himself well, the master or his foreman was there at the statute to say so, and a more truthful character was obtained in this way than could be procured by any registration-office. The remedy proposed was totally impracticable." There were other speakers for and against, but the argument is almost altogether embraced in the speeches of the Bishop and Mr. Torr. As the feeling of the meeting was seen to be going against the proposal, an attempt was made to show that in the establishment of register-offices there was no desire to abolish the hiring fairs. If, however, the movement meant anything, it must have tended directly to ignoring the latter. And the farmers, to whom, as the Bishop admitted, the consideration of the subject most properly belonged, would not have the proposition on any terms. The formal resolution to establish a "Servants' General Registration Society" was met with an amendment that the institution be rather called "The Lincolnshire General Servants' Amelioration Society" — and the amendment was carried by a very large majority, the numbers being thirty-one to seven.

We confess that our opinions go very much with this majority. There has been a vast deal of overstrained sentiment about our "white slave markets"—Where Will stands with a bit of whipcord in his wide-awake, or Jack mounts a curl of wool from his last place; and Mary comes in hopes of getting a better place than she ever would in her own hamlet. Beyond this, we do not quite see the sin or danger of a boy or girl going a little way from home. It is well known that our domestic female servants never do better than when they are out of reach of the meddling influence of "mother," or the continual promptings of some neighbour Busybody. We are not so sure, either, but that boys may become sharper, quicker, and abler men from the same change of scene—one, that in a higher station of life is considered almost a necessary part of their education. Of course they are never left entirely to their own control, and we cannot but refer again to Mr. Marshall's essay as to how they do really fare and prosper.

The immoralities of the Statutes might, as was suggested, be corrected; although even these we fancy have been a little overcoloured. Moreover, if Jack and Gill are not suffered to go to "a statty" they will go to a pleasure fair, or have their holiday out some way or other. These wholesale attempts to interfere with or revolutionize the habits of the lower classes have never, so far, resulted in much good. The Statute fair may be made more orderly, but for either master or man it is about the most just principle that has ever yet been devised.

Perhaps of all districts Lincolnshire was the last in which we might have expected to have witnessed such an agitation. The county has long been proverbial for the excellence of its agricultural servants, the good terms on which they stand with their employers, and the liberal manner in which they are treated. As Mr. Torr said, and said well, too:—

"He had had the good fortune to visit nearly every part of Her Majesty's dominions, and he had taken a special interest in the rural population of the three kingdoms; and he could say, 'without fear, favour, or affection,' that the Wolds of Yorkshire and North Lincolnshire possessed a peasantry equal, if not superior, to that of any other district. The only place he could point out as their equal in such a respect was the north part of Northumberland, where the cottage system existed in its perfection. He should be sorry to see the north of Lincolnshire copying from the south of England, where there were no statutes, but where the labourers were in a most miserable condition. The farm servants of North Lincolnshire were, however, comfortably housed and really well kept."

Is it not rather dangerous to interfere with the customs of people doing as well as these are?

USE OF GAS-LIME.

[In all our larger towns where gas is used for lights, there is a considerable quantity of waste lime thrown out from the gas-houses, lime being used for passing the gas through to purify it. We have various reports from farmers who have tried this, some in favour, some that it has no effect, while others have condemned it as rank poison to crops. Several inquiries have recently been addressed to us, one of which, from F. S. Hawley, of Binghampton, N. Y., we forwarded to Prof. S. W. Johnson, of the Yale Analytical and Agricultural School, requesting an opinion. His reply will throw some light upon the subject.]

TO THE EDITOR OF THE AMERICAN AGRICULTURIST.

The various contradictory opinions held among practical farmers, with reference to the value of gas-lime as a manure, are justified by the extreme variableness of its composition. When perfectly fresh from the gas purifiers, it is in general a rather dangerous appplication to any growing crop, or in contact with seed. Mr. Solomon Mead, of New Haven, Connecticut, informs me he once applied it in the hill to potatoes, and they never came up. A gentleman in Wallingford, Ct., applied it to grass land and to the roots of peach trees. The trees were destroyed, and the grass severely scorched, so that it did not fairly recover until the ensuing year.

It may be used in the fresh state upon naked fallows, especially when it is desirable to free the soil from slugs, injurious worms, or couch grass. What its action is upon vermin may be inferred from the fact that when fresh it contains a substance (sulphide of calcium) which is the actual ingredient in the depilatories and cosmetics, which are articles employed for removing hair. There is an account of its being thrown into a hog-pen with the intent that the swine should incorporate it with the compost heap. This was effectually accomplished, but at the expense of the bristles and hair of the hogs, which were, in a great measure, removed by the operation.

It is thought, too, that the odour of the coal-tar, which is mixed with the gas-lime in greater or less quantity, serves to dislodge insects and vermin; and it is sometimes sown in small quantity over young turnip-plants to prevent the attacks of the turnip-fly. In Scotland, it is largely applied to moss-land which it is intended to reclaim.

The quantity of easily soluble matters (sulphide of calcium, sulphite and hyposulphite of lime) is so variable, ranging, according to analytical data, from 2½ to 15 parts in 100, that we may readily comprehend how some gas-limes may be quite harmless if applied in moderate doses even to growing crops, while others, rich in these soluble and deleterious matters, destroy all vegetation.

It has been supposed that fresh gas-lime is valuable on account of the ammonia it contains. When the gas-lime is emptied from the purifiers in which it has been exposed to the gas, it has quite a pungent odour of ammonia; but the quantity, though enough to affect the nostrils, is in reality quite too small to have any great manuring value, and quite disappears after a few days' exposure to the air. Mr. Twining, of this laboratory, found in a specimen of perfectly fresh gas-lime, from the New Haven gas-works, but eight-tenths of one per cent. of ammonia. In a gas-lime from the gas-works at Waterbury, Ct., which had been exposed to the air for one week, he found but about four-one-hundredths of one per cent.

Fresh gas-lime may be advantageously used in composting swamp muck, &c.

By full exposure to the atmosphere, as when scattered over fallow-ground, after a time it becomes innocuous. The soluble caustic ingredients are converted into no less valuable a substance than gypsum (plaster); and then, after its odour and bitter burning taste have disappeared, it acts precisely like a mixture of lime and gypsum. How rapidly these changes take place, I have no means of knowing without making actual trial; but should presume that if a dressing of gas-lime be incorporated thoroughly and uniformly with the soil one week before sowing or planting, no harm could result to the crop.

In conclusion, your correspondent is recommended to use it, if he can get it more cheaply than other lime, at the rate of fifty bushels per acre on heavy soils, or ten to twenty bushels on light soils, making one application in three or four years. If fresh it should be put on the bare soil, and not on a crop. In case of corn or potatoes, it may be scattered between the rows, and worked in at hoeing time. If the gas-lime is white and tasteless after exposure to air for a time, it may be sown like gypsum.

It should be remembered that a wet soil will not be much benefited by lime, nor by any manure, unless in a dry season; and that a light dry soil is soon spoiled by lime, unless a good supply of organic matter be maintained in it, by means of stable manure, muck composts, or green-manuring. Lime and plaster, too, are at the best, even when they exhibit their most extraordinary effects, but partial fertilizing agents. S. W. JOHNSON.

DRILLING OF CROPS.

It was observed by the late Earl of Leicester, better known as Mr. Coke, of Holkham, that the Scotch farmers were most excellent cultivators of the soil, in that they drilled every root crop, as he had adopted that system *from them;* and at the same time they were the very worst imaginable in sowing the grains in broadcast, for he had used the drilling in rows of the culmiferous crops. The same very enlightened and patriotic individual strongly advocated leases of twenty years, and continued the threshing of grain by flail. The judicial Lord Kames of Scotland, who lived about 1770, very strongly recommended leases of twenty years, and as strongly urged the superiority of the ox over the horse for farming purposes, wondering all the while that a wilful blindness of daily growth seemed to prefer the horse, which was superseding the ox. The quick perception and powerful intellect of these gifted and enlightened individuals failed to rid the prejudice that threshing machinery diminishes labour, and to see that grain crops only reap the benefits of the root crop preparation, and do not confer any benefit on the land. The same organ which established the very large benefit of twenty years' leases, failed to perceive that nature has decided the superiority of the horse over the ox, for farming purposes, in the muscular formation of the animal, and that quick motions are in almost every kind of operations more effectual than sluggish actions of distant repetition. The late George III. farmed for thirty-two years at Windsor for the express purpose of showing that oxen were superior to horses, and the very contrary was proved; just as the chemists discover new things, or contrary things, in the progress towards an object which was intended. When prejudices surround and encumber such minds as have been mentioned, no wonder need be made that the common cultivators are tied and manacled by apathy and mental servitude.

The question between thrashing by machinery and flail is soon settled: the very object of machinery is to diminish labour on non-productive points, and to apply it to the increase of production, and not to the cost of manufacture, than which there can be no greater blunder in social economy. It relieves manual labour from the most brutifying performances, and leaves to it the nicer operations that are beyond its sphere of application; for machinery has its limits prescribed. The question of leases needs no discussion, but the drilling of crops may admit some useful notices.

The drilling of root-crops at the distance of twenty-six to thirty inches is certainly the most eligible practice that has yet been devised for the purpose of cleaning and pulverizing the ground, destroying the weeds, applying the manure, and preparing the land for the future crops. The drills are opened by the common plough, the dung is spread evenly along the hollow intervals, the drills are split by the plough, and reversed over the dung, when the seeds are immediately deposited in the freshly-stirred soil. This mode is most admirable in Scotland and the North of England, where the climate affords frequent rains and many dews, and where the soils are cool from being fresh-water loams of alluvial formation, that are superimposed on the primitive rocks. Over the southern half of England an arid climate succeeds, and a totally different geological series of deposits; marine clays, oolites, chalks, and greensands afford a most varied mixture of soils, which require very different implements and courses of cultivation. The soils are in many cases very open in the texture, and easily dried, and crumbly and cloddy from clay, and easily penetrated by drought. The Scotch mode of twice drilling the ground, by opening and reversing the drills, has been found to dissipate the moisture, by exposing the land so much during the driest season of the year; and on this moisture the success of the turnip crop almost wholly depends.

It has been adopted to sow, on the flat and drilled ground, the artificial manures with the turnip seed, by means of machines with lengthened coulters, which make ruts in the soil at stated distances to receive the contents of deposition. This method sows the seed in a parched dust on the top of the ground, which is always made during dry weather on tilled lands, and the rows being flat, the equal opportunity is not afforded, with ridglets and hollows, of cultivating the intervals with the horse-hoe. But on the lands above-mentioned, it is preferable to exposing the land by being twice drilled. All light lands are best sown with artificial manures, which may be best used in drills 27 inches apart, made with one furrow of the common plough, and the seed being immediately sown, and the drills rolled, nearly a flat state will be produced, and a fresh tilth will be enjoyed by the seed, without exposing the land to drought by lying in open drills. Two common ploughs will employ Hornsby's drop-drill, which splits the ridglets, and deposits the seeds deeply. It is an excellent implement. Light lands may be wholly prepared from the winter furrow by means of Finlayson's harrow, and being reduced by grubbing and rolling, and never turned up to exposure, the moisture of winter will be retained, and do much to secure the crop. The farmyard dung may be mixed with the land by the grubbing of the implement, and the ground drilled and sown as above-directed.

The root crops used in Great Britain are, potatoes, turnips, cabbages, and beet-root, which grow in roots in or close to the ground, and do not rise to height and impede the cultivation in pulverizing the soil and clearing the land from weeds. The horse-hoe can work during the whole season of summer and autumn, and the hoe and the hands of the weeders can be employed over the matured growth of the plants in cutting and pulling the weeds that grow upon the land. This admission of the tools of cultivation, throughout the season, constitutes the great value of these plants, as the soil is thereby thoroughly pulverized and cleaned by the operations. Beans allow a partial cultivation in the early summer; but the plant soon rises to height, and excludes the implements. The crop is, therefore, only a half-fallow; and the best use of it, in the county of East Lothian, in the south of Scotland, does not form a substitute for the bare wheat and turnip fallows. The drilling of peas and vetches is excluded, by reason of the plants quickly growing over the intervals, and prohibiting any cultivation; and the use of the plants consists in a close crop, thoroughly covering the ground, and smothering every vegetation below the shade. The land is mellowed on the surface, and freshened with moisture, and enriched with the decomposition produced by the exclusion of air and retention of moisture.

The very decisive advantages of drilling root-crops arise from the plants growing close by the ground, and thereby allowing the most complete fallowing of the intervals, and the cleaning of the whole ground from weeds. When the luxuriance of the crop does cover the intervals of the drills, there is still a liberty of hand-

pulling the tall weeds, which, with the previous scarifyings and hand-hoeings, finishes the process of fallowing and cleaning the land. These facts are so undisputed, that no further comment is necessary.

The benefits of drilling grain crops rest upon a very questionable foundation. The rows are narrow, and 12 or 14 inches distant, and do not allow the horse-hoeing in any effectual way: a very slight action only can be done. The operations of the hand-hoe are equally ineffective, by reason of the scuffling of the intervals being too shallow to admit the works of the hoe: the surface-weeds are cut, but no pulverizing effect is performed. The plants quickly rise into a height that excludes all subsequent operations behind a scarifying by the horse-hoe and one or two operations of the hand-tool. These slight processes effect no beneficial purpose, beyond slightly checking the small weeds that rise first in the spring. All later growths remain undisturbed, as the tall grains prohibit any work being done. The season of performing what can be done is much too short to produce any benefit.

Green crops are cultivated to obtain the roots as the valuable part, and without maturing the seed—a purpose very widely different from the use of grain crops, which are sown for the express object of obtaining the matured seeds as the value that is desired. The latter plants derive the benefit that has been conferred on the land by the cultivation of the root crops. The very opposite nature prevents any similar benefit being conferred by the plants on the land, and the idea of drilling corn had arisen with the minds that evaded the solid, and fastened on the superficial. No decisive proof has been recorded from a majority of similar results, that the produce of grains and clovers is larger from drilled land than from broadcast sowing; and until this proof be made satisfactory for more than one year, on a field alternated in equal spaces of ground with rows and broadcast, the drilling of grain must be held as an effusion of fancy, which has no substantial evidence for its support. The farmers of the Border counties made trial of the row cultivation, but soon relinquished it, finding no benefit from the additional expense, and that close luxuriant crops of grain produced by the root crop fallowing and manuring were more effectual in smothering weeds than any hoeings of the intervals that could be done. It is an application of labour to an object which cannot derive the benefit of the intention, and therefore the expense is misapplied, and produces no remuneration.

The evidence is much more ample of the superiority of thrashing by machinery over the flail, than of drilling grain being more advantageous than sowing in broadcast; and yet the boasted Holkham farmers, and many other cultivators of repute, persist in applying labour to non-productive points in using the flail at five times the cost of machinery, and in adding the expense of drilling grain to produce no result—a weakness of intellect almost incredible in these days of inquiry, when the torture of the rack is unsparingly applied for the behoof of agriculture, on every point of tangible application.

J. D.

AGRICULTURE AND POPULATION.

[TRANSLATED FROM THE FRENCH OF "LE JOURNAL D'AGRICULTURE PRATIQUE."]

The Academy of Moral and Political Science directed M. Léonce de Lavergne, one of its members, to institute and prosecute an inquiry into the actual condition of the rural classes in France; and, in order to execute his commission, that learned economist has completed a series of investigations which, in these late times especially, have attracted the attention of the most eminent publicists.

Amongst these studies there is one which presents itself foremost as an essential basis of the researches of M. de Lavergne, namely, that of the statistics resulting from the census of the population, as have been published officially in 1856. This administrative document states two facts, both important and characteristic for our epoch; first, in respect to the preceding quinquennial period, a relaxation in the increase of the population during the period from 1851 to 1856; and again—and this possesses a higher degree of interest with agriculture—a manifest depopulation of the country districts, in favour of some large cities, and especially Paris. Consequently, it was very natural that in a study of the condition of the rural classes, such facts, stated officially, should stand out in strong relief: public opinion had previously conjectured it, and the statistic surprised no one, when it came to be exhibited in figures.

We thus see a country (France), abandoning its old traditions, and inclining towards English organization, in the predominance of the urban over the rural populations. Is this a symptom of progress? or is it a symptom of decay?

There are to be found writers who, in their optimism, have looked upon this change of class in our populations as the undeniable evidence of progressive civilization. Starting upon the idea that the more agriculture advances towards perfection, the more it replaces manual labour by machinery, they are happy to find that the origination of great public works in cities has found employment for the rural populations for which agriculture has no further occasion.

The book that M. de Lavergne has recently published, entitled "Agriculture and Population," is, we may say, a true protest against these fatal tendencies of our rural populations to desert the village. Tracing to their origin the causes of this desertion, the author places in the first rank the inclemency of the seasons, and the centralization of expenditure in cities. The first has been, he says, the chief determining cause of the general depopulation of France, and that of the rural districts in particular; but (and this deserves the greatest attention) it is at the moment in which agriculture has the most need of all its resources, to struggle against the fatal influence of the seasons, that, in aggravation, it is seen to be simultaneously deprived of arm and capital by war and luxury—two causes to which are necessarily attached the centralization of expenditure in cities.

The war! it would be out of place to speak of it here, otherwise than to render homage to those rural populations, which, in that great trial of the country, have furnished so largely their contingent of men and money. But luxury! the centralization of expenditure in cities! that is another thing; for at the last analysis it is beyond dispute that amongst the causes that have attracted our rural populations into the cities, we must assign a chief place to this respective position of our cities and rural districts. In the latter, the insufficiency of the harvest, the only resource of the inhabitants, has produced misery, and closed the workshops of

private labour. In the former, the insufficiency of the harvest has been counteracted, more than elsewhere, by ingenious combinations, tending, on the one hand, to sell bread below the normal price, and, on the other, to create public works upon a scale till then unheard-of. Bread and labour assured, what more was required to attract the populations? They have only too well responded to the appeal, and it is thus that in the five years from 1851 to 1856, the total population of France increased only 256,194, whilst that of Paris, taken alone, has increased to the enormous extent of 305,354 inhabitants. From whence, then, arises this excess of the Parisian population, if not chiefly from the contingent made up of the deserters of our agricultural departments?

But this is not all; for we must not only look at the figures in this question of depopulation of the country districts: we must look also, and above all, at the quality of the emigrants. Now, it has been found that the requirements of war have exacted the formation of a numerous army; here is at once an enormous tribute levied chiefly upon the most effective portion, the most productive of our rural population. But we must not speak of this, for glory is the consummation of the tribute. Let us speak of another portion of the emigration—that which has recruited the army from amongst workmen, masons, carpenters, navigators, and other building workmen. Can we believe that the desertion of these has not been more sensibly felt in our rural districts, in that, generally, it acts upon those men in the strength of life, and such as in regard to intelligence and activity might justly pass for the *élite* of the working population of our villages? Truly such questions are quite common-place; for there is no one who does not know that in the actual state of popular prejudices it is those who are the least favoured by Nature and education who are left in our villages.

The arm of ridicule is very powerful in France, but frequently it is only the shaft of wit against good sense; and such is the course of things that, sooner or later—too late, unfortunately—good sense carries the day. A day will come, therefore, in which public opinion will do ample justice for that strange accusation launched against those writers who, in our day, have blamed the extravagant luxury of the cities. They have been represented as false puritans, as men who do not comprehend the necessities of our civilization; as pessimists, who, for example, would wish to see Paris laid in ruins. This is, in reality, the disastrous war. It is not necessary that Paris should cease to be embellished: the whole question is, to hold an even balance between the expenses which may concur in ameliorating a residence in cities, and those which have for their object the amelioration of the rural viability, the clearing of the downs and mountains, the management of the fluvial waters, &c. We are beginning to engage in this course of reparation towards the poor districts; and M. de Lavergne properly qualifies as a good law that, by virtue of which the State charges itself to execute the work of planting on the plains of Bordeaux to the extent of a sum of 6,000,000 francs.

A deputy of the Legislative Corps, M. Guillaumin, justly remarked, in the discussion on the expenditure of the Budget of 1858, that out of a sum total of 1,716,986,190 francs, the budget for public agricultural works figured simply to the amount of 1,850,000 francs; appropriated to the rendering healthy or renewing the forests of Sologne, Doubes, Gascony, Brisse, and Corsica—all countries in which fevers decimate the population. Certainly, looking at these sums, the first so large and the second so small, we cannot say that the rural population have taken the lion's share. And yet, at a period in which sanitary questions, so interesting to the working classes, have assumed so much importance, what work can be more beneficial than that of rendering healthy the unfortunate countries which up to the present time have known little of our civilization except from the tax-gatherer and the recruiting-serjeant? What unknown miseries exist in these countries! which, after all, demand of the State only what it has done for the richer ones—namely, roads for traffic and sanitary works.

As a general principle, M. de Lavergne is not one of those writers who demand on all occasions the intervention of the State in matters of interest, either agricultural or manufacturing. He does not wish the State to do too many things; for he knows that that system might be construed, to the great detriment of agriculture, into an increase of taxes and functionaries. He prefers much that the country acquire the habit of doing by itself, so far as possible, its agricultural and industrial affairs; for he is persuaded that it is, above all, by the exercise of individual exertion, that a nation learns to conquer and preserve all that gives riches, power, and stability. We can only applaud such doctrines, being those of a good political economy. They teach the love of labour, and divest governments of the terrible responsibility imposed upon them by contrary doctrines, especially in what concerns salaries and the question of sustenance. To this extent, therefore, it is desirable for all, governors or governed, that the doctrine of individual initiative, thus understood, should penetrate into all social circles. The result would not be that the State would have nothing to do for agriculture; it would still be at least evident that the public expenditure ought to bear only upon objects with which the citizens, whether separately or in association, cannot be employed. Now in the actual state of things, it is certain that many great agricultural works, and operations of public utility, such as the replanting of mountains and downs, or the rendering healthy insalubrious countries, constitute in the highest degree works executed at the charge of the whole country. Compelled to become a manufacturing and commercial nation, we have for a length of time already concentrated the strongest part of our public resources in the improvement of the richest districts; and it is time that the poor ones, the disinherited countries, should, in their turns, also have a place in the budget of public works. To say that these poor districts will never reimburse by their own riches the advances of the budget, is to view a great question on its weakest side, and to forget what those countries, now provided with roads and openings, were themselves, before they became the theatre of great public works.

M. Guillaumin, the deputy of whom I have spoken already, said again, in the Corps Legislatif, in continuing his idea of public agricultural works: "Suppose that a capitalist, entering upon a healthy soil, commenced by making costly constructions, by furnishing his stables with selected beasts, by establishing from them splendid teams—by creating a museum of perfect instruments, without reserving capital to purchase manure, carry out the drainage, marling, irrigations, &c., which are, in cultivation, reproductive expenses; should we not have a right to say to that capitalist, 'You have badly arranged the employment of your funds, and have neglected the expenses productive of riches'?"

Well! it is not necessary that a State that is called France should subject itself to the same reproach. In other terms, that the expenditures of luxury and utility, for the embellishment of cities and those dispersed over wealthy territories, should at the same time overlook those great blots called La Bresse, La Sologne, and many other countries. In these there are productive expenses to be incurred. It does not simply consist in increasing our grain and cattle, but to carry labour to the hand of

the workman in the field; in a word, to enable those who remain in their native country to find something else there than fern and buckwheat-bread, unhealthy pond-water, and, true penance of Tantalus, immense lands to cultivate, but no labour. And then, when this work of reparation shall have been accomplished, we might, without reverse of the medal, be justly proud of our country. Instead of progressing towards the English organization in what relates to the repartition of the populations, we shall have preserved our old and strong French organization—the predominance of the rural populations over the urban, the scattered populations over the agglomerated.

Undoubtedly the progress of mechanical agriculture, like that of mechanical manufacture, tends to the substitution, so far as it can, of the work of machinery for that of men. But does it follow that this desirable substitution has been, up to the present time, one of the causes to which we are allowed to attribute the depopulation of the country districts? Have we a right to say that the thrashing-machine, the drill, the horse-hoe, the steam locomotive, the haymaking machine, &c., &c., have in any degree whatever diminished on our farms the demand for hand labour? To maintain such affirmations would be to forget, in my opinion, that the more agriculture is improved, the greater its need of the arm—and let us mark well this fact—the arm of intelligence. This is what appears to have escaped the notice of many writers, who, on this question of population, have spoken of the wants of agriculture in men, and who understand manufacturing much better than rural economy. More familiarity with this last science would have taught them that amongst the elements that determine the choice of systems of cultivation, it is necessary, before all, to accord a very great importance to the amount of the labouring population. Show us the least populous country, and forest and pastoral agriculture reign there; ascend a ladder, and you find arable culture mingled with fallows and pasturage; see, in short, a country well peopled, and you are in presence of intensive culture, culture without fallows, culture with stabulation of cattle, and predominance of roots, artificial forage, manufacturing and garden plants, &c. It is quite true that machines are multiplied in proportion as the earth is better cultivated; but as, on the other hand, the demands of consumption increase, it happens that, up to the present at least, the increasing fertility of the soil causes the extension of manufacturing and gardening cultivation, which implies also a greater need of hand-labour. And not only are more hands necessary, but, what is more important for the working population, the rural labour formerly concentrated upon the harvest season has become better distributed over the whole year. Thus workmen are required for spring tillage, for the autumn harvests, and for winter works in the agricultural districts. Hence, less stoppage, but a more equally-balanced labour, better sustained, and better remunerated.

Such is the truth of the case. Machinery has in no respect occasioned the emigration of the rural population; since agriculture, otherwise in presence of larger outlets, has never had such extensive need of hand-labour as since the period of the improvement of machines. It is therefore not true that the attraction of the cities over the rural populations can be a good thing; nor is it true that this attraction is a sign of high civilization. On the contrary, this unclassing of the populations is a fact not to applaud, but to combat with, in its exaggerations. Let us not forget, as a last analysis, that it not with French as with English agriculture. This latter, whether it be from its markets or from the nature of the soil and climate, employs itself little except upon forages, corn, and cattle. The former, much more complex, unites to the production of alimentary commodities, those of vines, mulberries, olives, fruit trees, manufacturing and horticultural plants, in the open fields. The small culture therefore predominates over our territory; and the small culture signifies the rural population in the greatest number.

All these ideas have been developed by M. de Lavergne, in several chapters which he has devoted to the special study of cattle, machinery, agricultural and forest products. Written under the impression of the visits made by the author to the Exposition of 1855, these chapters are not simply a technical description of the objects that the several nations had sent to the great gathering at Paris. Much higher is their bearing, for they are in truth a study of the whole of European agriculture. Thus, when the Exposition terminated, the author, always pre-occupied with the condition of the rural classes, takes, at setting out, many of those ideas which, with more or less opportunity, have been thrown into public discussion.

In many of these ideas appears commercial freedom; that is to say, the suppression, or rather the progressive reduction of customs' duties exacted at the frontiers of each nation. I will not enter into the discussion of this so-much controverted question; and besides, there is not a single reader of this journal who does not know that M. de Lavergne does not in any respect believe that our agriculture is efficiently protected by the sliding-scale and other fiscal arrangements. I will only say that, in opposition to many ancient organizers of free exchange in France, who explained to us, as was done in England for the agriculture of that country, that French agriculture was enriched at the expence of the consumers, M. de Lavergne has clearly shown that enormous difference which, in this respect, exists between the agricultures of the two countries. In fact, the free-exchangists of Outre-Manche might justly support themselves upon the excessive dearness of agricultural products, and by that argument organize a league against the import duties on cereals. But in France to talk of the excessive dearness of commodities, and of the illegitimate profits of agriculture, was in truth to place the spirit of system above the reality of facts; to discredit political economy; and at all hazards, to ruin the doctrine of free-trade in public opinion. Real science, or that which is based on the study of things, ought therefore to be pleased that M. de Lavergne has re-opened this question, and placed it upon its true foundation. Such men advance the sciences slowly: it is not necessary to repudiate them because they sometimes deceive themselves; but when a principle is badly advanced, it must be replaced.

It is impossible that M. de Lavergne should not know his own opinion on a measure that would tend to nothing less than the re-establishment of an order of things incompatible with our present habits. Listen to certain reformers, and they charge the subdivision of the land with the backward state of our agriculture; they consequently demand that we introduce into our legislation the illimitable liberty of willing property at death, and the right of entail. What does M. de Lavergne think on this subject? A partisan of free competition, he admits only one means of disallowing the sale to the small proprietor, that is, to do better than he, as may be done in certain situations. In the background, therefore, are those superannuated combinations, which, powerless to reascend the course of time, would be useful only in raising new storms. "The law of equal division," says our author, "is the flesh and blood of France. We cannot touch it without danger, at least in its essential dispositions." This is saying plainly that M. de Lavergne does not push the fanaticism of this law of equal division to a disregard of the inconveniences of the

826th article of the Code, which allows to each of the heritors to demand his part *in kind*, of the furniture and fixtures of the succession. This *régime* of absolute equality has conducted us straight to that of instalments, of enclosures of pieces of land; that is, a *régime* that multiplies inordinately the ditches, fences, rights of passage, &c.; which hinders the reform of bad distribution of crops, and the execution of great works connected with drainage, irrigation, &c. Here, then, there is something to do; and M. de Lavergne thinks that, for example, one of the heirs should be authorized to take possession of fixtures exceeding in value his share, on payment to the others of three per cent. interest, and two per cent. redemption, with the power of repaying the whole on the principle of a *credit-foncier*.

With regard to the soil, the principal element of agricultural labour, M. de Lavergne demands the reduction, and even the suppression of the rights which involve the real property mutations. This is well spoken, and it was moreover the advice of M. Gasparin; these rights are, in fact, one of the first causes of the enormous debt of the proprietary. They bar the idea of all improvements; and one of the best means of encouraging agriculture will unquestionably be to facilitate the mutations.

Again, with regard to the soil, M. de Lavergne has met with a publicist who places the existence of communal property in the list of the most efficacious means for ameliorating the condition of the rural classes. Upon this, a protest is urged by M. de Lavergne, who knows very well that the land that is every body's is nobody's, and who, in that frame of mind, reproaches the communalities when they go beyond a certain proportion with the population, for the maintenance of poverty, idleness, ignorance, and thoughtlessness.

After the soil come capital and labour. Here agriculture is, it may be said, in presence of two deserters, who have given notice of passing over to the enemy. The enemy! that is undoubtedly the true expression, when it is intended to point out those manufactures which do nothing for the soil, whilst they consume nevertheless its produce.

Once more we must not be misunderstood. Manufacture and agriculture cannot be enemies under a reign of free competition; but their productiveness may be singularly changed in a social state in which the urban populations have remained longer protected than the agricultural population. Indeed, such is the primitive idea, resulting from the economic studies of M. de Lavergne. Centralization has so far ruled our situation in France, that almost all causes have combined to develope the riches of the cities rather than those of the country. Thus professional instruction occupies itself with recruitment of the army, with medicine, with the bar, with the arts and manufactures, rather than with that of agriculture. So again, the majority of the great families reside in the cities, where they find life more agreeable. And we are astonished that capital and labour desert the fields, when they have so high an example set them. We are astonished that the peasants, surrounded with lands which should be the best investments for rural savings, have become the holders of railway shares and debentures of French and foreign stocks!

O progress of the age! Formerly, when the country notaries made out inventories of inheritance, what did they find in the house of the easy peasant? Good closets furnished with good linen, and granaries well furnished with corn. What do they find now? Papers and public deeds negociable at the Exchange. It is the fulfilment of the proverb, "Other times, other manners." It remains to be seen which manners are the best.

But what can be done to alter all this? On this question M. de Lavergne shows himself faithful to all his economic antecedents; that is to say, that his advice is not of those who would upset all social order. He has interrogated the science of political economy. He knows on what conditions capitals are created and manufactures prosper. He has confidence also in the good sense of our rural populations, who, in times of great crises, have always known how to get us out of them. He hopes, too, that more than one prodigal son will return sooner or later to the village; for, after all, it is there that France will always reckon upon the most labourers, and, at need, the most soldiers.

On the other hand, it behoves us to prepare for this future. Agriculture will become what agriculturists themselves become: like as in all the social circles, high as well as low, these should be able to treat on a footing of equality with the representatives of other professions; and then not one measure of general interest will be taken without the agricultural interest receiving full satisfaction. All depends on that; it is necessary that agricultural France should be able to constantly enlighten the Government, for there are no more certain means of rendering it stable and powerful, to the profit of the country. Large culture and a large property, above all, have much to do, to march on an equality with the small proprietor and small culture. We may say that in this respect we are not in equilibrium as a nation.

If the number of cultivators were sufficient for success, or rather, to place the agricultural element into position amongst the other elements of national power, it is evident that French agriculture, the employment of twenty-five out of the thirty-five millions of inhabitants, would be in a position to make the rural spirit predominate in the public mind; and, with the rural spirit, all the principles of order and progress which it comports. But we are not deceived there. If the rural spirit exists in our country, let us admit, at least, that it is much more alive in the subdivided districts than in those of aggregated culture. It is not, therefore, surprising that it should experience ideas, manners, and aspirations of the intellectual level of the dominant population, of which it is the representative. This is why we find in it, in so high a degree, that love of family and property, and all those domestic virtues, which, in a word, are, without dispute, one of the most solid bases of our social order. But by way of retaliation, it is not amongst these laborious populations, almost constantly bowed down to the soil, that we must seek for those connected ideas, that knowledge of general interests, and that superior education which our modern society requires. Consequently it is no longer there that we must seek for that useful counterpois, which, amongst the English, places the defence of agricultural interests under the protection of men who can, know how to, and will, cultivate them.

It is, therefore, essential that we should not confound the rural spirit of large culture with that of small culture. The latter guarantees order in this respect, that small workmen have neither time nor even desire to employ themselves with anything but their harvests, cattle, sales, and purchases. The former, quite as strenuous for order, more particularly guarantee progress in this sense—that, sharing in the movements of general interest, it can give the impulse to public opinion, and does not conform itself to receiving the word of command. In a word, if there were in a state only small cultivators, the big-wigs of finance, manufacture, and commerce would easily gain the ascendancy; which would be a misfortune, for it would be the absolute reign of certain interests.

It will not be thus: science and capital come to the fields; and, thanks to these levers of progress, there is amongst our rural society a class of men who, without

the rights of seniority, majorats, or estates in tail, will know how to prevent the excessive sub-division of the soil. To this class of men we may address the language of M. de Lavergne; for, precisely because it loves the truth and disdains false complacency, because it desires employment for the workmen and preaches by example, there are none, who better than they, have the right of not being suspected of a bad spirit, when they raise their voice in favour of useful reforms, and point out certain dangers to the citizens. M. de Lavergne has found an echo in this part of the population. It is, I think, an excellent proof that he has in his writings known how to unite moderation of language with firmness of opinion. Let us not, however, consider him exclusively as the advocate of large culture: that would be to forget all that he has justly said in favour of small culture, for which he professes, with truth, a very particular esteem. So alsoin what regards manufacture, it is unnecessary to suppose that he has placed it in antagonism with agriculture: far from it. A man of profound views, he has arrived through political economy at rural economy, through the whole to the part. That is to say, he is not exclusive, and loves all the branches of human labour. He has been, I repeat, struck with the depopulation of our country districts; he seeks by the light of science, and in the domain of individual energy rather than in the intervention of the State, a remedy for this public danger. In short, M. de Lavergne has made once more one of those good books, which displays to us all the grandeur and utility of the part that agriculture is called upon to play in France, and that to the advantage of our population, whom it behoves to preserve its rural character. E. LECOUTEUX,

Former Director of the Cultures of the Agronomic Institute of Versailles.

THE LATEST PATENTS FOR PLOUGHING BY STEAM.

The next patent machine for tilling and preparing and, adapted to "steam traction," which we have to notice, is that of William Smith, of Little Woolstone, Bucks. (Patent dated September 7th, 1853. No. of patent, 2,121. Price of specification, 6½d.) The invention claimed in the patent is the manner of combining implements, such as the patentee has before used as subsoil ploughs, into one. The implement represented in the drawing is in general appearance like the cultivator or grubber. The tines, or "implements" as they are designated in the specification, are three in number. Of these, the central is the only one provided with handles; the frames or bodies of the other two are in all respects similar to this central implement. Two cross-beams (*a a*) are provided for combining the three into one. The fore parts of the beams or bodies of the implements are connected with a bar (*b*) which runs parallel to, and some distance before, the cross-beams (*a a*). At each end of the bar (*b*) a vertical screw, with an eye at its upper end, is placed; through the eyes of these rods the draft chains fixed to the stems of the cutting implements are passed, and extended forward and attached to the whippletree connected with the bar (*b*). The whippletree is inclined, as required, to either side, by chains attached to each end: these are taken up and hooked at points in the handle of the central implement, so as to be within reach of the attendant. Wheels are provided, one to each of the two outer implements; and in some cases, on stiff land, the patentee states that each implement has its own wheel. The height of the wheel and of the implements are adjusted in the frame in manner similar to the coulter and wheels of the plough. The tine, or cutting part of the implement, resembles in form the tine of the ordinary grubber or cultivator.

The patent next in chronological order which we propose to notice under the present division of our subject, is that granted to John Allen Williams, of Baydon, Wilts. (Patent dated 17th of June, 1854. No. of patent, 1,325. Price of specification, 1s. 6d.) This invention relates to an arrangement of plough or cultivating apparatus for working land, "Whereby," says the specification, "a much superior cultivating effect is obtainable than is possible with the common or other existing forms of ploughs or cultivators." The cultivating implements represented in the drawings attached to the specification resemble closely in arrangement and detail the ordinary plough, with its share, mouldboard, and coulter. The peculiar feature of the arrangement is the method by which various adjustments can be given to these ploughs: they can, for instance, be lifted vertically out of or adjusted to any distance from the soil in which they work, the ploughshares being attached to a series of horizontal bars (*a*) running from end to end of the framing of the machine; these bars being provided with eyes sliding up and down on vertical guide-bars (*b*) fitted to the back of the framing. Three of these plough bars or beams (*a*) are stated by the patentee to be a convenient number. To the front of the framing, vertical guides (*c*), corresponding to (*b*), are fitted: these are provided with block pieces (*d*) which slide up and down. To projecting rings or ears made on these block pieces (*d*) the extremities of the horizontal plough bars (*a*) are jointed, the ends of the plough bars being furnished with a double eye or fork. By this arrangement, if obstacles present themselves to the ploughs while in operation, the ploughs give way to the obstacles; the plough bars (*a*) rising behind, and turning on the jointed block pieces (*d*) sliding on the front guide bars (*c*), the plough bars, with their attached ploughs, are lifted simultaneously out of contact with, or adjusted to any distance from, the soil by the following means. At each end of the framing carrying the guide bars (*b c*) a set of loose pulleys (*e*) are hung; chains connected with the plough bars (*a*) at each end pass over these pulleys; the chains (*f*) attached to the ends of the plough bars at the back of the machine being at once connected to lever handles (*g*) placed within the reach of the attendant. The chains attached to the front end of the plough bars (*a*) pass over their corresponding pulleys, and are connected with rods or links which extend along the framing, and are connected at their opposite ends to the chains (*f*) connected with the lever handles (*g*). By depressing these handles (*g*) both ends of the plough bars are raised simultaneously. The lever handles (*g*) work in segmental slides provided with holes, through which pins pass, and are made to regulate the extent of "lift" of the plough bars (*a*). Each plough bar is also capable of being lifted up independently of the others, by means of a small handle fixed to the back end of the bar. The vertical guide bars (*c*) are capable of being slightly inclined, so as to give a corresponding lateral inclination to the coulters and turn-furrows of the ploughs, and to enable them "to turn the furrows more efficiently when ploughing a hill-side or sidelong ground." The lateral traverse of the frame which gives the inclination to the guide bars (*c*) above referred to,

is effected through the medium of a handle situated at the back of the machine, within the reach of the attendant. This handle is fixed at the end of a rod reaching from one end of the machine to the other, and provided at the further extremity with a pinion working into a rack fitted on the hind bar of the sloping wrought-iron frame carrying the guide bars (*c*) working in slots attached to the main framing of the machine. The whole apparatus is supported in a long rectangular framing, of length corresponding to the number of ploughs employed. This framing is supported by two large wheels, running loose upon separate axles, placed at different levels to suit the depth of furrow to be made in the inequality of the surface over which the machine travels. A support for the framing is obtained at the back end by a smaller wheel set upon a swivel centre capable of lateral adjustment. In ploughing, the off-side front wheel runs in, and is steadied by the furrow cut by the previous traverse of the plough, whilst the corresponding wheel runs on the unploughed ground. This arrangement involves the necessity of having the near side-wheel higher by the depth of the furrow than the off side, this being attained by a nut and screw in a rack and pinion adjustment. The ploughshares or cutters are set one behind the other, as regards the direction of the plough's traverse; so that the off or right-hand plough begins to cut first, the second one next, and the near one last: the hind wheel, following immediately in the newly cut furrow on the near side of the plough, receives a guide from the last formed furrow.

Although not exactly in chronolgical order, we may here notice a second patent granted to Mr. Williams (date of patent Dec. 7, 1855; No. of patent 2,766; price of specification 9d.), for a ploughing or cultivating machine, the general arrangements of which closely resemble that which we have above described; the plough or cultivator bars being supported and adjusted by the same mechanism; the framing is, however, supported on a pair of small swivel wheels in front, and by a pair of larger wheels at the back of the machine. An important claim in the patent is for "a peculiar share." This consists of an ordinary plough share, with a left-hand pin formed in it. "A small turnfurrow of a peculiar construction is fitted to the plough body, and consists of a steel plate, fitted or formed with a knife or cutting edge, at right angles or thereabouts to its surface, working under the furrow, and severing the same, so that one portion of the furrow slice will be cut and laid over the other part, thus leaving an uneven surface for the harrow teeth, in the subsequent operation of harrowing, to lay hold of." The central beam is the longest, and has its cutting implement nearest to the front of the framing, which is angle or pointed, so as to suit the different lengths of the beam. By the arrangement adopted, the two implements on each side of the central beam come into operation successively. The pins of the shares are made broad enough to intersect each other's course; in this way the entire surface is operated on. A claim is also made in the patent for a combination of implements in one frame, to act as a rafter frame and a horse-hoe. The ploughs in the ordinary machine can also be taken out, and "drag" tines substituted.

The last patent machine or implement, coming under the present division of our subject, is that of Richard Coleman (patent dated May 28, 1855; No. 1,222; price of specification 1s. 10d.) The patent is for improvements in the construction of land rollers, and an implement for ploughing and breaking up, or scarifying the soil. That part of the patent which refers to the latter class of implements is for "a method of combining a series of ploughs in one machine, for turning up or otherwise tilling the land." Two, three, or more ploughs are mounted on a frame, in a position diagonal to their direction of motion, so that one acts in advance of the other, and breaks up and turns over a breadth of land equal to the number of ploughs employed. In the machine shown in the drawing four ploughs are employed. The ploughs are provided with parallel-faced stems, which slide in sockets, made in the main framing. This framing is supported in front by two swivel wheels, which are free to turn round on the vertical axis, supported by the front of the framing to the axle of the wheels. Near one end a rod is jointed; this is carried along the front of the framing, and jointed to the short arm of a hand lever, placed within reach of the attendant. By turning this handle the rod acts upon, and causes the axle of the wheels to move out of the line, so that the machine may be guided as desired. The centre of these wheels is also adjustable, so as to bring it nearer to or further from the ground, by a lever jointed to the upper end of the vertical one attached to the axle of the wheels. The framing is supported at the back by two large wheels, which are capable of adjustment, by means similar to that employed in the well-known "cultivator" of the patentee. The plough-frames are fitted to sockets in a second framing; this is placed above the main framing, and moves in vertical guides attached to the main framing, and also by rods sliding in vertical guides made in a bar or tie, which is placed across the lower framing. To the upper frame the coulters are suspended in the same way as the plough-frames; the upright stems of the coulters, as also of th plough, slide in sockets made in the lower framing. The upper frame, with its plough-frames and coulters, is elevated and depressed at will by an ingenious system of levers. A cross shaft (*a*), fitted with a lever handle, by which it can be turned on its bearings, is supported in bearings fitted to the main or lower frame; and carries at each extremity bell cranks or levers, with two arms, one of which is horizontal. These horizontal arms are connected by jointed rods to the middle of the upper framing carrying the plough-frames, while the other arms of the bell cranks are jointed to the lower arms of a second series of bell cranks. These second bell cranks are fitted to studs in the lower frame, the other arms of these bell cranks being connected to the upper frame by levers. The upper frame is thus entirely supported by jointed rods, connected with a series of bell cranks. By moving the lever on the cross shaft (*a*), the whole system of cranks and levers is operated upon, and the upper frame lowered or raised as required.

In a modification of this apparatus, also described in the specification, the upper moveable frame is dispensed with, and the plough-frames and coulters are raised by a rack-and-pinion motion.

THE ARTIFICIAL MANURE QUESTION.—At a meeting of the Oxford Farmers' Club, on Wednesday, Jan. 14, the following resolution, proposed by Mr. Mein, and seconded by Mr. Coggins, was carried unanimously: "That this Club considers the use of artificial manure is still too much limited; that Peruvian guano, as a standard, is the best top-dressing for corn crops; farm-yard manure, guano, nitrate of soda, and bone-dust for grass land; that mixed manures are the best for root crops; and that without a liberal use of artificial manure the present extent of land in this country could not be kept in cultivation, as there is nothing that has tended more to assist high farming than the introduction of artificial manure; and, finally, that this Club does not consider that the decay of the root crop is attributable to the lavish application of manures." At the same meeting, Mr. Thomson, of Culham, was re-elected Chairman of the Club for the ensuing year.

THE CAUSES OF THE DECLINE IN THE PRICE OF CORN.

The continued decline in prices of grain, but especially wheat, has begun to alarm the agriculturists, some of whom consider it the prelude to a permanent range of prices below what it can be produced at. There are, however, many causes operating at the present time to occasion this decline, which are not likely to continue; nor, some of them at least, to occur again; and to these we are about to direct the attention of our readers, with the view of relieving their minds from apprehensions which have little foundation in facts.

First. The wheat crop of 1857 was, beyond a doubt, above an average one, probably to the extent of one-fifth, taking the usual produce at 16,000,000 quarters. This would make the produce of the last harvest 19,500,000 quarters, or about one-and-a-half million quarters below the average consumption. A *very large* portion of the crop was thrashed out in the first four months of the season, so that although the American supplies of both wheat and flour were withheld during that period, there was an ample supply of native-grown wheat, and importations enough from the Baltic and other near ports of foreign wheat to supply any deficiency that would otherwise have arisen from the non arrival of the produce of the United States.

Another minor cause is the state of the potato crop, which on account of the prevalence of the disease, and doubt of their keeping good in store, have been brought to market freely, and as largely consumed by the small growers instead of bread. This has materially affected the consumption of the latter article since harvest; but as the potatoes are rapidly being used up, the working classes will soon have recourse to bread again as the only farinacious food, and now cheaper than potatoes.

Thirdly, the state of the money market, which has affected every other market in the kingdom, especially that of corn, not only as having diminished consumption by throwing a vast number of hands out of work, and thus reducing their means for procuring food, but also by inducing the millers and dealers to contract their purchases to their immediate requirements, and thus checking whatever disposition might otherwise have existed to retain stocks of wheat and flour.

Fourthly, the rescinding of the French decrees against the exportation of grain. We have left this to the last, not because of its unimportance, but because it demands a fuller explanation than any other question connected with the subject. That the late decree has had a material and very natural effect upon the price of wheat and flour is evident, from the course prices have taken from the very day it was promulged on the corn market; and *that* effect is easily accounted for. If *any* produce market is amply supplied, a small excess in permanent operation will tend to lower prices, as a small permanent deficiency will have the contrary effect. Now, the quantity of French wheat and flour imported, and in process of being imported, into the United Kingdom, is trifling compared with the consumption, but it is *in excess of the demand*, and consequently takes the place of so much native wheat, also being *fresh* and of good quality. Whether the French will be able to continue exporting even to the present small extent is a question that remains to be solved. Certain it is, however, that their own production and consumption will not leave room for such an export trade as to make up to us the loss of the American supply; and, if we may judge of the future by the past, we should say that even *this season* they cannot continue to export, without leaving themselves bare of wheat. The following statement will bear us out in this opinion.

By a reference to the French official returns of exports and imports of grain for the last twenty-five years, we find the quantity of wheat, reduced to English measure, to have been respectively as follows:—

	qrs.	qrs.
Imports....	18,485,387	or 739,415 per annum.
Exports....	10,564,913	422,996 ,,
Excess of imports	7,920,474	316,419

The whole of these statistics are a bagatelle compared with those of the United Kingdom; but they are important to us, as proving that, at present at least, France cannot grow wheat permanently for exportation. Even if we take the last eleven years, which are considered by the French writers on the subject to have been seasons of great agricultural prosperity, we find the excess of imports to average still more than for the above twenty-five years, being 337,764 qrs. per annum. Either, therefore, the quantity grown is smaller, by a contraction of the area of cultivation, or the consumption of wheaten bread has increased in France. We believe that the former has been the case, for the following reasons.

First, the continual subdivision of the land under the present law of inheritance, has a manifest tendency to withdraw cultivation from cereals, and multiply the kinds of produce. This is, by some of the French economists, considered the glory of the system, as affording subsistence to a much larger population. But, on the other hand, the most far-seeing men in that country deprecate the system as forming a direct barrier to all agricultural as well as social improvement, whilst it keeps the whole agricultural population in a normal state of poverty incompatible with the well-being of the state. A proof of this may be found in the statistics of the population, which in five years, from 1851 to 1856, has increased only to the extent of 256,194, or rather less than three quarters per cent. But the most remarkable feature in the census is, that whilst the whole of France has increased only 256,194, the population of Paris has increased 305,354; from which it is evident that in the agricultural districts the population is rapidly decreasing,* Paris being only the type, in regard to population, of the other large cities of France; and the same process is going on in all the rural districts. It appears also, by the accounts of well-informed men, that it is not the very poorest of the rural population that are thus fleeing from their native villages, but the most intelligent and well-to-do of the peasantry and mechanics of all kinds. Nor is it from the increase of agricultural machinery that these men are driven to emigrate, for improvements of all kinds find enormous difficulties in penetrating into the interior of France. Nor are the French peasantry as a body able, in a pecuniary point of view, to adopt such improvements, or any measures for the amelioration of the soil or increase of their produce. In this

* See the article on Agriculture and Population in another column.

respect they are in a normal state, from which they can never be galvanized by the Government; and nothing less than a complete alteration of the law of inheritance will produce that change.

Under present circumstances, therefore, the English has nothing to fear from the competition of the French farmer. Both countries were blessed last season with a productive harvest, and low prices are the consequence, aggravated by other and temporary circumstances, which can hardly occur again in a simultaneous combination.

It is a great alleviation to the present state of the corn-trade that meat and all animal produce continue at remunerating prices. In this, neither France nor any other country can injure us. It is true, by the system pursued by the French Government in its interference with the several trades, and the butchers amongst the rest, the retail price of meat is kept down to a certain standard, like that of bread; but the consequent increased consumption has raised the price *to the butcher* beyond what would pay a profit upon an export-trade to England; so that our graziers have the market pretty well to themselves. We much question also whether, with our improved system of agriculture and the use of machinery, we cannot compete with any corn-growing country in the world, when the expences of transit, commission, &c., are taken into the account.

USES OF THE SNOW.

Pleasant as is the revolution of the seasons, with the manifold aspects they present, one can hardly observe the approach of winter without feelings of regret and sadness. This is the case especially with those who delight in the observation and study of Nature, or are devoted to the pursuits of agriculture. The tourist finds little pleasure in excursions amid beautiful scenery, if meanwhile he is frost-bitten; the landscape painter must fold up his sketches with benumbed fingers, and hasten homeward; the botanist—where are the flowers he loved so well?—the geologist, entomologist, and indeed the student in almost every department in natural science, finds his sphere of observation reduced to very narrow bounds; the gardener must cease his delightful labours, and the farmer can no longer sow and reap, and gather into barns, but must witness for many months an exhausting drain upon his stores without any replenishing streams.

But is there no bright side to this picture? While our gardens and fields are buried in snow, and our roads are blocked up by drifts, are there no benefits in this winter covering which make up a partial compensation for its admitted evils and discomforts? We think there are; and such as most concern the man (the farmer) who seems most to suffer from it. It is this aspect of winter we now propose briefly to consider.

The old proverb that "snow is the poor man's manure," is believed to have its basis in scientific fact. Chemists tell us that analysis reveals a larger per-centage of ammonia in snow than in rain. This, at least, is true, that snow is a powerful absorbent, purifying the air, and returning those impurities as fertilizers to the soil. Melt in a clean vessel a mass of snow which has lain a short time on the ground, and the taste will detect foreign elements in the water. This is most manifest in the neighbourhood of large towns. The harshness and dryness produced in the mouth by drinking snow water, and the unpleasant effects on the skin by washing in it, are ascribed to the impurities it contains. The disease called *goitre*, prevailing in Alpine regions, is also attributed by some to the use of snow water. A certain writer illustrates the absorbent power of snow thus: "Take a lump of snow (crust answers well), of three or four inches in length, and hold it in the flame of a lamp; not a drop of water will fall from the snow, but the water as fast as formed will penetrate or be drawn up into the snow by capillary attraction. It is by virtue of this power that it purifies the atmosphere, by absorbing and retaining its noxious and noisome gases and odours."

Furthermore, it prevents exhalations from the earth, and having absorbed them, returns their fertilizing properties to the soil. Hence, marshes and stagnant pools become inodorous in winter, and the unwholesome effluvia of vegetable matter everywhere decaying, is retained, and with the melting of the snow in spring, is taken up by the soil. So much as this, at least, we fully believe—that "the poor man's manure" is as good as some of the "patent" fertilizers of the day.

Snow helps the springs and mill-streams in winter. Were the ground naked from fall to spring, and frozen meanwhile several feet deep, the springs would give out, and water-wheels of all descriptions stand idle. As it is, however, the snow prevents the frost from penetrating to a great depth—especially in the wooded hills, the fountain heads of springs and streams—and by their gradual melting keep up a supply of water for man and beast.

Not the least important use of snow is the protection it affords to tender vegetation. Even in northern latitudes, there is a multitude of tender and half-tender indigenous plants, which require more or less protection in winter. Nature provides for them most wisely. She hangs over them the branches of neighbouring trees and bushes, gathers about their roots a many-folded blanket of dry leaves, and last of all, spreads over them a fleecy mantle of snow. With this covering they pass through the severest winter safely; but were they transplanted to exposed situations, they would die at once. But besides, our gardens and fields are stocked with plants and grains which are the natives of warmer climates, and need protection still more. Sweep off the snow from our wheat fields and meadows, and at least a portion of the crop would be winter-killed. Some of the choicest herbaceous plants in our gardens, brought from milder regions, will pass unharmed through our coldest winters, if only they are covered with snow. So of many tender shrubs. With their branches fastened to the ground so as to be covered with snow, they hybernate in Canada about as well as at the tropics. We have seen the English yew, several feet high, come out in spring well browned above the snow-line, while all below was green as emerald. The Japan quince, by no means a tender shrub, the deutzias, *Spirea prunifolia, Forsythia viridissima*, the scarlet-flowering currants, &c., &c., frequently lose their flower-buds, if not their branches, above the snow, while all underneath is unharmed. The buds of peach-trees are often killed in severe winters; but if a few branches happen to get bent under the snow, they produce a splendid show of fruit. Scientific travellers in Siberia have recorded instances in which, with the temperature of the air above the snow at 72 degs. below zero, that below was 29 degs. above zero, showing a difference of 100 degs. Dr. Kane, in his "Arctic Expedition," mentions finding underneath the snow, at lat. 78 degs., "the andromeda in full flower, and saxifrages and carices green under the dried tufts of last year. Here, too, the silene and cerathrium, as well as the characteristic flower-growths of later summer, the poppy and sorrel, were already recognizable." * * * "Few of us at home," he continues, "can realize the protecting value of this warm coverlet of snow. No eider-down in the cradle of an infant is tucked in more kindly than the sleeping dress of winter about this feeble flower-life."

When the snow falls early in winter, and remains until spring, the ground is seldom frozen at all. And if it becomes frozen a few inches deep before the snow falls, the heat of the subsoil thaws out the frost above it, and the superincumbent snow prevents another freezing, so that in early spring the ground is soft and ready for the plough and spade.

The aid which the snow renders the farmers in clearing up swamps and getting out muck in winter, and in hauling wood and lumber to market; the peculiar brilliancy of the snowy landscape when lighted up by the sun; the sport of sliding down hill for the boys, and of sleigh-riding for children of larger growth, are considerations not to be omitted in numbering up the uses of snow.—Country Gentleman.

ON TRUNK-DRAINING.

A trunk is the body without the head and limbs, the main stem without branches and ramifications. It is the chief part of an organized growth, the foundation of an artificial structure, and the base of any operations: it forms the support on which any structure rests, from which it receives the formation, the existence, and its value. The trunk is the largest member of any production, and the body of any congregation of parts: the use of it receives the adhesion of other parts, and renders to them its own assistance.

By trunk-draining are understood the water courses that receive and convey the discharges of water from the small drains, which intersect and ramify any entire superfices of ground, and under the general designation are comprehended rivers, brooks, rivulets, artificial open cuts, and the large covered drains that are placed along the lower end of fields and lands for the purpose of carrying the water from the under drains. These conveyances perform the same offices with the body of a man, and the trunk of a tree: they communicate with the branches, and uphold the existence by administering support and relief. The functional parts of organized bodies would be surcharged and suffocated with excrements and exudations if the vent by the trunk was not provided to relieve the superfluities that are cast off. The voidances find an egress by which to discharge the dregs of the process of elaboration. The small drains, of the branches of the performance, collect the water from the land, and find by the trunk an exit by which the water is relieved, and their function progresses without stop or interruption. The connection of the small drains with the trunk must be intimate and free in the action. The latter must be ready and sufficient to receive and convey the discharge of the small drains, in order that the utility be not impeded, nor the operation disturbed. Nature has shown the essential purpose of a trunk, or principal stem in all its organized productions; the bole of the tree supports the ramifications and the foliage; the stem of the herb upholds the stalks of the leaves, and the fruit, and the universal provision in all cases exhibits a base or support for every composite erection. The inorganic world is similarly composed: the river receives and conveys the waters of the smaller streams, and discharges the whole contents into the general reservoir of the sea; the rivulets receive the washings of the surface of the ground, and the harder materials of the globe are seen to uphold the softer, not only as a base on which to rest, but as a source from which to draw the reservation and increase of the composition. Without a trunk, main support, or principal stem, no production or operation can be legitimately entertained or executed.

A river being the discharge of collected waters into the general reservoir of the sea, is the trunk which relieves all the subordinate agents of the burden incurred by the discharge of the functions of office. The bed of rivers is naturally in low grounds in which the waters have scooped a channel that is very considerably lower than the surrounding surfaces. The fall towards the sea of all countries affords a descent for the waters, that is more or less rapid according to the declivity of the surface, and the obstacles that are encountered. In most cases, the descent of rivers constitutes a conveying trunk for the collected waters that effectually relieves the smaller collections, and affords a ready outlet to the contributions. Low grounds and alluvial flats are the only occurrences which may be insufficiently accommodated by the trunk of the river as a conveying channel for the collected waters of the surface of the ground; heavy falls of rain will flood the river, and cause an overflow of the water above the banks, and over the adjoining grounds; during which time the discharge will be stopped of the conductors of water into the river. To keep the river within the banks, and prevent the overflow of water on the lands, grassy mounds of earth are raised along the course of the river, in a line back from the water's edge, so as to allow ample room for the increase of flooded waters without unduly confining the stream to compel a violent breach of the embankment. During the time of low waters the descent will be sufficient for the escape of the waters that are discharged: during floods the escape will be stopped, and a reflux of the waters will stagnate into any opening or hollow that can be found. It is this effect that has to be guarded against on low grounds over which the waters flow, and in several cases the difficulty is not small of remedying the evil. A floodgate may be placed in the opening of the embankment, through which the water is discharged into the river, which will be shut by the outside pressure of the swollen river, and hinder the reflux of any water behind the embankment. But the usual discharge of water will be prohibited from making its escape, and will stagnate and overflow if it has not room for expansion. This stagnation, by flowing backwards, will hinder the usual discharges of the smaller contributions, impede the action, and inflict damage, until the decrease of the swollen rivers, by lessening the outside pressure on the flood-gate, enables the water collected in the inside to force it open, and find a discharge. This plan is sometimes the only adoption that can be used, circumstances prohibiting other recourse; and the attendant evils must be borne. The collections of water that join the flat course of the river should be led into it at the sharpest possible angle of divergence, so that, when it joins the chief current, no backward pressure is felt, but a willing reception is found into the general movement in one and the same direction. In many cases this direction may be impossible; but, whenever in any way to be attained, the advantages of it are very large. During the time the river is flooded, the damage done by the water itself would not be of much moment; but earthy solutions are held in suspension by the collected waters of the country, and, being stagnated and introduced backwards into the smaller drains, a sediment is deposited which the weak discharge from the small drains is unable to remove, and it becomes firm ground, and fills up the drain. It is even forced upwards among the filling materials of the drains, leaves an earthy residuum, which remains and impedes the reception of the surface-water. The largest open cuts cannot prevent this consequence, as the extent of capacity will be overpowered by the body of waters. Much ground will also be occupied by many of these excavations, which should be confined to one main leading cut that remains uncovered. The conveying direction of this cut along the stream of the river, and joining it at a very sharp angle, will best serve the purpose, if at all available. Flood-gates are liable to the heavy objection of congregated waters inside the embankments, which remain during the time of the floods, and inflict damage. When a very slanting direction is effected, the backward power of the water

in the river is almost none: it continues in being lost at every step from the right angle to the point of no angle at all, when it entirely ceases. This method must be used in every possible case of adoption, and will prove more generally useful than flood-gates, for the reasons that have been given.

The alluvial flat which the river traverses will often be bounded by high lands on both sides, that have a hollow ground along the base, and which is often low as the river, or below its level. This situation is often very appropriate for an open cut, into which much water will flow, from the high ground on one side, and from the flat space between it and the river. In the case of a small drainage, the discharge of the ramifications will open into this cut, which will run a parallel course with the river, and join the current at a sharp corner, when the river inclines to that side of the valley, and impinges against the high grounds. A flood of the river will stop the current of water in this cut; but the extent of it being capacious, and the flowing of it along with the rivers, will make the damage less formidable than in any other way, as the depth of bottom will be considerably below the level of the small drains. At all events, the backward force will be less than in any other arrangement.

The descent of rivers is often much accelerated, and the discharge of water increased, by cutting off the corners of its course, straightening the line, and thus lowering the level of the water. Where a straight line cannot be got, the rounding of corners will receive the conflict of waters with the obstacles of its course, put the eddying mass into motion, and increase the onward progress. Jetties of stone-work will be required at the sharpest turnings, which being placed to receive the current of water at a sharp angle of incidence, will throw it off at a similar angle, and direct it into the mid-stream of the channel, when it will move quicker from the agitation. Very sluggish movements of water in alluvial flats may be accelerated in this way, the level deepened, and a conveying-trunk obtained for the small drains.

The other case of rivers affording an insufficient trunk for the discharge of waters collected from small drains occurs on extensive lowlands, fens, and marshes, through which the streams meander in a devious course in search of the sea, and having little or no onward fall, and the bed raised by the sedimented mud, to or above the level of the surrounding grounds. Embankments are in this case the very first resort, with openings through which may pass the tributary streams that flow from the country on both sides of the river. When these minor streams are of considerable size embankments must confine these waters also, and conduct into the main river. The streams being joined, the same level of waters will be preserved, and the same flow of current will prevail. These collections of water afford a very bad trunk for the purpose of draining; but modern discoveries have tended wholly to remove the evil. Slanting courses are to be adopted, as has been mentioned, and every outlet sought at which a stream can be introduced into the main current. When no outward passage can be found the water collected into the open cut from the small drains is led by the same conductor to the lowest corner of the ground, and immediately behind the embankment a deep pond is formed, from which the water is raised by the pump of a steam-engine, and thrown into spouts, which convey it over the bank into the river, from whence there is no return. By this means the collected waters are reduced to the lowest level, and no overflow or stagnation ever happens. The mighty power of steam has in this case overcome all perplexities, and has reduced into a nutshell the trunk draining of the low lands that are below the level of descent. It is certainly the extreme application, when all other propositions fail, or are seen to be impossible; and it had better be at first adopted, than after a large expenditure has failed to reach the object. It is a sure agent and an effectual operation in every case of its power,

Brooks are a trunk of the same kind as rivers, receiving and conveying waters that have been collected by the smaller currents. In order to favour the quick passage of the water the courses will, in many cases, require to be deepened and straightened—especially the last—and also widened, where the quantity of the collected waters is found to be too large for the room that is contained within the banks. The natural channels that have been excavated at random will be insufficient to answer the modern purposes of drainage; widening will be the best alteration, and always with a depth below the bottom level of the small drains. When the quantity of water is the largest in the brook its top level should be below the drains, or, at least, not impede the discharge. Allowing waters a wide extent of course is much better than deepening the bed: expansion of the volume diminishes the depth and, correspondingly, its force, and being spread in width below the level of the drains, no stoppage can happen from the water rising to the orifices. A wide water-course of medium depth forms the best trunk for draining—the depth has little impinging force against the banks, and any swell of the water is lost in the width of the course. The bed is hollowed in the middle, where the ordinary current may flow, to prevent the wandering of the water from bank to bank, and alternately impinging against and tearing the confines of its course. A depth in the centre and a sloping shallowness on the sides and below the banks, on which the flood can spread and roll along, constitutes the most eligible course for all small streams, as brooks and rivulets, always allotting the extent of the bed to the quantity of water that has been found to prevail at all times and occasions. Circumstances may not allow this adoption in the full extent, but the performances of the kind may be made to tend in that direction. The bottom level of the small drains may be on the top of the slope of the side of the course, which the highest flood may never reach, and the opening of the drains never exposed to damage. Gentle elevations of surface will readily allow this arrangement which may be used in many modifications.

The improvement of brooks, as trunks for draining, is done as for rivers, when the courses run through flat ponds and level countries. The means must be adopted of widening, deepening, and cutting straight the courses and rounding the corners, by which to accelerate the discharge of the water, and quickly relieve the small drains of the contents. The top level of the water in the brook must be below the bottom level of the small drains, so that the discharge of the latter is always to be seen, and the highest flood of the brook must not exclude the view, except for a short time. The ultimate efficacy of brooks as a trunk drain depends upon the main river, of which it is a tributary, at least in the near approaches of its course to the bed of the river. Here the ground is generally flat, and the course of the water may become sluggish, and rise to the small drains, when the object becomes apparent of having the river's course sufficient to receive and convey the additional bulk that comes to be admitted. The brook is a river in miniature, and must be adapted by the means that have been mentioned to receive and convey the discharge of the smaller drains in the like manner that the river has been altered and improved in its course, to admit and

carry away the contents of the brooks and smaller streams of water: the river is the chief trunk, and upon it all the ramifications depend.

Rivulets are currents that are inferior to brooks in the quantity of water, and in summer many of these streams are wholly dry or reduced to an amount that scarcely forms a current of any kind. When the bed of a rivulet constitutes much the most eligible trunk to receive the small drainage of contiguous wet grounds, the natural depth may be too shallow to receive the water from the bottom level of the small drains; in that case a wholly new channel will be cut, following the old course in all proper directions, and traversing new ground in order to find a preferable situation for the intended purpose. This performance will be often much more eligible than repairing an old course into an imperfect channel, by reason of an originally wrong direction in the natural current of the water. A straight or moderately-curved line of course will thus be procured in many cases, where the old channel will not afford a more efficient performance in every respect. Rivulets are seldom sufficient by the natural formation to receive the contents of drainage—the depth is too shallow, and the course too much blended and tortuous to evacuate the small drains, and afford a quick and ready passage of the water from the places of collection. New cuts must be made to suit the surface of the ground, and the intended purpose of access from the small drains, when a much more advantageous course will be obtained, and a double purpose effected.

Watercourses will most frequently show the position of trunks for the conveyance of water, which seeks the lowest grounds in which to flow, and which must be used for a similar purpose. New cuts will chiefly deviate from the old channel in passing through the corners and angles of the bended course, lessening distances and producing straight lines—the same ground will be traversed, and the same point reached at last. When rivulets are flowing streams during the whole year, with a considerable quantity of water, and the course meanders over a flat alluvial country, the management is the same as of brooks, as the terms are nearly synonymous. A near following of the old course is to be preferred in opening a larger passage for water along a hollow ground: the surface water naturally falls into it, and the lowest position is generally marked by the natural search of the water when left to its own performance. In draining the new cut, the essential must never be omitted that the course runs in the lowest position, and on no account must leave this most proper and indispensable place. Whatever line the course may exhibit, straight, bended, tortuous, or curved, this position must be strictly preserved: the discharge from the small drains will reach the trunk with every facility, encounter no obstacle, but have an uninterrupted descent from the extreme first end of the formation, into the last conveyance that relieves the current, and finishes the purpose.

Here this rule admits no exception, of placing trunk-drains, or conveyances of water, in the lowest positions of the ground. Water must be ever descending, and never stagnate, and far less be directed to the smallest acclivity, as when the trunk-drain leaves the lowest position. In draining of every kind, there must be a drain in every lowest position; and the rule is equally unexceptionable in the smallest case, on the varied and undulated surface of ground, as with the trunks that convey to the rivers the discharges of water from the small drains of the field.

Artificial Open Cuts

Are made to answer the purpose of brooks and rivulets, to receive the water from the small drains, and convey it so a trunk or general conductor. A river traverses a country, and receives the water of many districts; brooks and rivulets pass through landed estates, and act as trunks for several farms; while artificial open cuts serve the purpose only on one farm, and for several divisions of land, and probably only for one field. The proper position is in the hollow places to which the water runs and flows over the surface during floods, and where no natural bed has been made by the water. In these places, the first performance is to excavate a cut of extent sufficient to receive and convey the water that will be directed into it by the small drains, and with a fall, to induce the regular descent. The cut may receive water on both sides of its course from the sloping grounds, when it will constitute a trunk of the proper kind. The width will be settled by the quantity of water that demands a passage; and the depth must not be under four feet of vertical height. This depth will receive the water of the small drains from the bottom, and permit a constant current in the cut, without stopping the orifices of discharge. This open cut sometimes constitutes the boundary or division of fields of land, when the size will be made sufficient for that purpose, and have the necessary fall to discharge the water. This excavation is an artificial brook or rivulet, and must be made on the plan that has been previously described. Large quantities of quickly-flowing water will tear the banks of soft alluvial earth, which must be guarded by rows of stakes driven into the ground, and backed with large stones, laid among gravels or coarse earths. Rapid descents of water will hollow the bottom and undermine the banks, when the bed must be pitched with stones flat in shape, or edged as curbs. This consequence shows the necessity of making the channels rather wide than deep, allowing the water room to spread, and thus destroying the power of its force. When a heavy current impinges against a bank on either side of the cut, the stream must be directed into the mid-channel, and guarded to flow in it.

Artificial cuts being destined to remain as trunks for conveying water, and in many cases to be the boundaries of divided fields of land, the excavation must be done on permanent grounds, by which to drain the adjoining lands, and effect the purpose of a dividing fence. The banks will be guarded by hedges of thorns or by a paling-fence on each side, and so far from the bank as not to be sunk by any slip that may happen. In other cases, the banks will be wholly open and unprotected, when the cut will form the fence, and must be deep and wide for the purpose. The banks are gently sloped, according to the nature of the soil, and best when the small drains are on a level with the highest flood that has been known.

Large Covered Drains

along the lower ends of fields and lands are placed for the purpose of receiving and conveying the water from the under-drains. The most general position is along the inside of the fence, and as near to it as the foundation will allow; the excavations are covered on the very just principle that no open drains remain within the fences of a cultivated field of land. Open side-drains cause a loss of ground, an awkward ploughing of the headlands, and prevent the animals that graze the field from getting close to the fence for shelter, which in cold climates is a matter of considerable attention. The depth must be 3½ feet or 4 feet of vertical height, 3 feet wide at top, and 2½ feet wide at bottom. The small drains will run into it at a right angle or some smaller incidence, and the water must flow into a body of materials in the larger drain that are open to receive it. Where stones can be got, the best provision is a culvert of about a foot square, built with sides and cover of durable workmanship. The depth of one foot of broken

stones is laid over the culvert, an inverted grassy turf covers the stones, and the loose earth is levelled to the top of the ground. In alluvial countries, where tiles are used for the purpose of draining, the culvert is formed by placing two longitudinal rows of large tiles made for the purpose, which are covered by the usual fillings of the drains. A large tile is turned to receive each small drain, and with stones an opening is left in the side wall to receive the water from the small tributary drains, which fall a few inches of declivity from their own bottom to the large drain. This declivity ensures a free discharge from the small drains, so that no stoppage can happen.

Few fields of drained land will discharge more water than can be contained in a square culvert of one foot, and when the large drain has a fall to keep the water running, which is done by a very small declivity. The covered drain will discharge the water into a brook or rivulet, of which the depth must freely receive the water that comes to be admitted, which must not rise above the top of the culvert of stones or of large tiles. Each trunk drain that receives water must be fitted for the purpose of receiving the contents of the smaller provisions of draining. The whole systematic value depends upon this aptitude being adjusted and continuously upheld. Any breach destroys the connection, and makes a hurtful disruption. In every case a declining level must be got and maintained throughout. The damage ceases when water is delivered into a channel into which no small drains are discharged; the course may then be more interrupted, and the waters move more slowly; but where a general drainage occurs, every point must be free and uninterrupted.

In many cases the water from the small drains, after escaping from the orifices, will traverse, before reaching the river, all the intermediate trunks that have been mentioned—brooks or rivulets, open cuts, and covered drains. The last-mentioned conductor will convey the water from the field where it is collected by the under-drains, and discharge it into an open cut or brook, which may immediately receive an adjacent small drainage into its current. The formation must be capable not only of receiving a collected stream of water, and conveying it along, but of reducing the top of the current below the level of the adjacent small drainage, to admit the contents freely and without impediment. It is best that all small drainage of waters be collected by a covered drain or open cut, and discharged by one mouth into a brook or rivulet. The covered drain being firmly erected no derangement can happen, and there is only one orifice to be attended. This mouth of discharge must have a very free outlet; and if it joins the receiving current on a level, the direction must be turned to the line of the main stream, and join it at a sharp angle. In this way the currents are joined in the flowing of the waters, and no pressure is exerted which can stop the continuation of the moving fluid. When a brook receives the contents of small drains throughout the whole course from the mouth of covered drains to the passage into the main river, the importance is most evident that the trunk affords a ready acceptance and uninterrupted conveyance to the collected burdens, which must not be allowed to stagnate or lose the onward progress. When the upper portion of a brook in its course is a receiving trunk, and the lower part a conveyance of water, the passage of the fluid will be less regarded in the latter part; the stream may be deeper, and the movement slower and more sluggish. A depth of water will not stop any discharge of small drains, and therefore the course may be less regarded; but in the upper part, where the special purpose consists in the trunk receiving and conveying water from the under-drainage of wet lands, a most vigilant attention must be exercised to keep the current of water in constant motion, and the highest level below the bottom of the drains, in order that a free discharge be secured to every orifice of water. This chief point is ever to be pushed forward for attention.

The drainer who knows his business, on having determined the line of the small drains of any ground to be perforated by cavities below the surface, will seek the lowest point or points to which the collected waters will fall, and look for the outlet by which the discharge must issue. Having found this point, the examination will proceed along the rivulet or brook, and ascertain the efficiency of these trunks to receive and convey the water; if insufficient, the beds must be improved as before directed; and if the course be distant from the point of the collected waters, an artificial open cut must be made, to act as a connecting trunk. When a cut or brook, or any secondary channel or water, reaches another property of land, and finds insufficient outlet, that property must provide a proper discharge for the current, and transmit the water that comes for admittance. Water is a burden that must be received from higher grounds by the lower situations, and conveyed over the extent of the latter, not only without injury to itself, but also to inflict no damage on the property from which it descends. Every landed estate incurs this responsibility.

Having reached the main outlet by which the collected waters descend from the small drains to the river or chief conveying trunk, the examination proceeds along the rivulet or brook, observes every defect, and suggests the remedy by marking every proper position. When the river is reached, beyond which no inspection is required, the level of that receiving trunk is accurately taken; and if the backlying country is flat, the spirit level is applied to denote the rise of every progress from the river, in order to ascertain the descent that can be obtained. In this way the descent is traced to the mouth of the covered drain which discharges the collected waters of the under-drainage, and the cutting of each excavation accurately determined along the whole course. The downward progress from the highest-drained lands to the lowest receiving trunk observes and inspects the courses of water as they are presented to view, and satisfies the inquiry of necessary outlets. The retracing of the steps adjusts every connection of the streams, and puts the whole arrangement into working order.

It is advantageous that the trunk drainings that have been mentioned are done for a time previous to the execution of the small drainage that must discharge the collected waters into the channels of conveyance. In all situations where the fall that can be got does not amount to a descent of running water, but barely moving or slightly removed from stagnation, the previous performance of the trunk drains will afford an inspection of the sufficiency of the executions for the intended purposes. If the regular descent is anywhere interrupted, and a stoppage is perceived, the whole line of conveyance must be again very accurately surveyed, and the levels ascertained, by what means and in what places the remedy is to be applied, in order to remove the deficiency that exists, and to promote the intended object. Deepening of the beds of water-courses can only be done in summer, when the quantity of water is small and the channel nearly bare; hence the intervention of one summer at least is necessary in such cases, that an opportunity may be given of deepening the bed of any brook, rivulet, or open cut that has been seen to be too shallow during the floods of winter. At least one year should elapse from the execution of trunk drains to the performance of small drainage; and both purposes being done in summer, a winter will intervene to show the capability of the conducting channels, and the rectification can be performed during the summer of the small draining. An elevated

ground of under-drains may not be any way affected by the non-efficiency of the trunk or trunks; the stoppage may not reach the height of the situation, nor be large to inflict damage anywhere. But in many situations of several fields of small drainage delivering the contents into open cuts, rivulets, brooks, and even into rivers, the least degree of insufficiency in the trunks of conveyance will rise into damage. In these places a small fault may cause a large damage, and spread a wide devastation; in higher situations a large deficiency may do little hurt, or none at all, by reason of the circumstances of the position. But in every case of high or low grounds, of flat or elevated positions; the immediate receiving trunk of the small drains must be in the top level of its water, below the bottom of the ramifications, in order to convey away freely the discharged contents. If the current does not flow from the orifices in a purling stream, any stagnation must not rise to cause a reflux into the small drains. This is the chief accident to be prevented, and it forms the main purpose of trunk drains. The attention paid to it is equal to the care of small drainage, and it must precede any operation of the latter kind. The object is twofold—the collected water is received and carried away, and stagnations are removed.

FORMATION OF AN AGRICULTURAL ASSOCIATION IN ESSEX.

A meeting of the committee appointed on the 18th of December to consider the best means of applying the £336—part of the surplus subscription for the Royal Agricultural Society's Meeting in 1856—to the advancement of the agriculture of the county, was recently held at the Shire Hall, Chelmsford. C. Du Cane, Esq., M.P., presided; and there were present—W. M. Tuffnell, Esq., Colonel Brise, W. F. Hobbs, Esq., Mr. J. Clayden, E. Round, Esq., J. W. P. Watlington, Esq, J. O. Parker, Esq., J. S. Thompson, Esq.; Messrs. Christy, R. Baker, K. Viall, Burrell, Page, &c.

The CHAIRMAN having read a letter from Sir John Tyrell, in reply to an invitation to attend, and another from Mr. Gurdon Rebow, expressing their approbation of the proposal to establish a county society, said he thought it would be unnecessary for him to make any lengthened introductory remarks on the object for which they were assembled, as they must be all aware that in consequence of the liberal response made by the county of Essex in aid of the great meeting of 1856, a surplus fund of £540 remained. At a meeting of the general committee held on the 18th of December last, it was resolved, after some discussion, "that the surplus funds, &c., after applying £200 for the erection of a pedestal for the Sebastopol gun, in the High Street of Chelmsford, be devoted for the advancement of agriculture, and that a committee be formed for carrying it into effect." It was also resolved that a number of gentlemen named should be a committee for carrying out that object. As chairman of that committee, up to the commencement of the present meeting, he had power to make additions to it, and accordingly he had added the names of Mr. T. Kemble, Mr. T. B. Western, Mr. Cornell, Mr. Mechi, and Mr. Perry Watllington. Now they were assembled here again to day, to discuss and decide upon the application of the surplus of £336 to agricultural purposes; and if he for a moment thought there was likely to be any difference of opinion as to the method of applying it, he might be inclined to leave the suggestive part of the business to others, and sit down; but as he was in hopes they would all be unanimous, and believing that all their thoughts ran in the same channel, he ventured to take the initiative, and to state at once that he thought the possession of this sum, contributed for an agricultural purpose, presented them with an excellent opportunity for the institution of that which was a desideratum in the county—an agricultural association (Hear.) Considering the size and importance of the county, the high rank it held amongst the agricultural counties of England, the great names to be found amongst its agricultural men, he might say renowned throughout England for agricultural and practical skill, he thought an association of this kind could not fail to be a great boon to the county at large. Of course it would not be his province to enter into the details of such an association. These would be matters for serious consideration on subsequent occasions. But perhaps he might state the kind of association he had in his mind's eye. It was founded on the model of those he saw established and working successfully in Suffolk and Norfolk, meeting once a-year for the distribution of prizes for agricultural stock and implements, and such other branches of agriculture as might be determined on by the committee. He also thought there was another point which would be material—that was, that the annual meetings should itinerate to the different towns in the county, such towns being selected as might be hereafter named by the committee. He was aware that objections might possibly be urged to the course he recommended them to adopt. It might be urged that the experiment had been tried, and had failed; that not long since there was an agricultural society in this neighbourhood, which, after dragging on a lingering existence for a few years, died a natural death. But he would say to those who adduced this argument that 14 years ago and the present time were two very different periods in the agriculture of the county. We had witnessed great changes—great progress had been made; and in nothing had this taken place more than in the agriculture of the United Kingdom. Therefore he would hope that an agricultural association, established at the present period on the basis named, would meet a very different fate from that of its predecessor, and would probably enjoy a long and prosperous career of general utility (cheers). There was, however, another objection of a more serious character—that the establishment of one grand county association might have the effect of checking the career and cramping the means of the numerous Labourers' Friend Societies established throughout the county, and now pursuing so useful a course. He should be losth to recommend a plan that would in any way retard the career of those societies, convinced as he was of the great practical good they effected amongst the labouring classes; but he thought by confining themselves in this great society to the branches of agriculture he had mentioned, and steering clear of those branches of husbandry which it was the province of the Labourers' Friend Societies to foster and promote, they should indirectly, if not directly, confer on them a great benefit; for the higher the perfection they arrived at in agricultural implements, the greater would be the demand for well-skilled labour, and the more would be valued that industry and sobriety amongst the labouring classes which it was their object to promote (Hear). Such was an outline of the scheme he proposed to them, and he should be happy to receive their suggestions, assured that at whatever end they arrived, it would be creditable to themselves as a committee, and conducive to the cause of agriculture in general (Hear).

Mr. J. CLAYDEN (of Littlebury) said he came from a distant part of the county, and having taken pains to inquire the feeling upon the subject in his district, he thought there was a prospect of fair and continued support for an association of this kind, and if well formed it would certainly be likely to succeed. They had had in their district a good society, which was certainly defunct, but its machinery still remained, to promote the object of an association of this kind. Much, however, would depend on the support of the landed proprietors; and he would suggest that they issue a few circulars, canvass the different districts of the county, and adjourn to March, when it should be seen what support they were likely to receive; for they would require a tolerably good sum, £500 or £600 a-year he should say, to support an association of this kind. If the proposition met the support of the landowners, the farmers, he believed, would respond to it heartily, and he earnestly wished to see it carried out. Perhaps Essex was not so much a breeding county as some others; but with fat and store stock united he thought they might have a good show, and a good society; he should say, let it not be too circumscribed (Hear). He moved "That the surplus fund of £336, arising from the subscriptions to the meeting of

the Royal Agricultural Society, at Chelmsford, in 1856, be applied to the formation of a County Agricultural Association, for the aid and advancement of agriculture, and the promotion of enterprise and emulation amongst the owners and occupiers of land."

Mr. R. BAKER said he had great pleasure in seconding the motion; he felt that Essex was standing far behind other counties in regard to agricultural societies at the present moment. They had had one at Chelmsford, one at Colchester, and one at Saffron Walden, all flourishing for a time; but it happened with local societies that after a time competition ceased (Hear). Therefore travelling from town to town would perhaps be the best mode of embracing the stock of the whole county. Still he thought there should not be more than three or four towns at which the meetings should be held, for transporting stock was an expensive concern, and the places selected should be those most convenient for the railway, or they would find their shows would be deficient. The benefits of these societies on a large scale had been and were fully appreciated; those little societies prepared the way for larger ones; and thus the shows of the society would prepare the county better for the Royal Agricultural Meeting (Hear). The details, however, of the association would be matters for serious consideration; but let them once establish the principle, and the details would follow, and he believed they should go on successfully.

The CHAIRMAN put the resolution, and it was adopted unanimously.

Colonel BRISE said he did not think there was much difference of opinion as to the objects for which they were met, and he was happy to think there was to be an association of this kind established, Essex having men eminent in agriculture throughout the kingdom, who would give them the benefit of their experience and ability. The association, he believed, would be the means of promoting to a great extent the agriculture of the county; nor did he think, after the appropriate observations of the chairman, that it would interfere with the Labourers' Friend Societies; whilst it being an itinerating association, going from place to place in the county, would instil a little competition into all parties (Hear, hear). He thought a subscription ought to be opened at once, and that the matter should be left till they ascertained the opinion of the county on the subject. He moved—

"That a meeting of the association be held annually at such towns in this county as may hereafter be named, for the exhibition of stock and implements, and the distribution of prizes in those and such other branches of agriculture as may hereafter be determined upon by the committee."

Mr. W. FISHER HOBBS said he was glad to find that the view he took of this matter on a former occasion had met with the unanimous approbation of this meeting; he must also express his satisfaction at the observations of the chairman in opening the meeting, which he had no doubt would have the approbation of the landed proprietors and the tenant farmers of the county generally. The remarks of Mr. Clayden and Mr. Baker proved the feelings of the farmers on the subject, and he would reiterate their statements as to the feeling of the agriculturists in his own neighbourhood. His object, however, in rising was to suggest that they should not bind themselves as to where they should go in different years. Let them admit the principle of itinerating, but he should rather suggest that the towns should be left to invite the society; not that they should ask the towns to allow them to hold their meetings there. With this understanding, he should be happy to second the resolution. Before, however, they could get the society in working order there was a great deal that was required to be done, and much would depend on the intelligence and activity of the secretary (Hear, hear). He must be a man known to, and mixing up with, the agriculturists, so as to be at all times able to communicate with them and solicit their subscriptions. They would also require a good working committee, not a large one, for the purpose of framing the rules of the society; and it would be necessary to meet day after day before anything could be prepared for the general meeting. It was a question, too, whether there should be one general meeting or two in the year. They had tried both in this county, and sometimes they had succeeded and sometimes not. There had been a spring meeting for store animals and the sale of wool, and then at Christmas a fat stock show. He thought at first they had better not attempt too much; they should have a good meeting once a year, either in May or June, or perhaps in September, when they could have an annual ploughing match and a show of good roots, and where seed corn would be exhibited and competed for. He thought Mr. Baker would agree that, as to seed corn and roots, they had not the competition they used to have. There were other points, too, not usually taken up by societies of this description, which he thought might be dealt with in a manner beneficial to agriculture.

The resolution was put, and unanimously agreed to.

Mr. PERRY WATLINGTON moved—

"That the Society consist of president (to be elected annually), vice-presidents, a committee (of which the vice-presidents shall be *ex officio* members), and members: and that a yearly subscription of five guineas entitles a subscriber to the rank of vice-president, and of half-a-guinea and upwards to become a member of the association."

He was no practical agriculturist himself, but he had taken some interest in the various Labourers' Friend Societies, and he felt no fear at all that such an institution as had been suggested to-day would do any injury to these societies in the different localities (Hear). In a grand society of this sort, carried out in the way which had been stated, he saw nothing that could interfere with them.

Mr. J. CHRISTY, jun., seconded the resolution, which was adopted.

Mr. W. M. TUFNELL said he thought there could be no possible doubt that an agricultural society, based on such principles as would command universal support, must be of great benefit to the county. He confessed that whatever misgivings he might have had on the subject, they had been very much removed by the feeling he had heard expressed to-day (Hear), and he was quite sure the best way of promoting the success of such an association would be by all putting their shoulders to the wheel, and having a long pull together (cheers). He was glad to see present gentlemen of great practical character in agriculture from all parts of the county, as this was more satisfactory than if they were all from one locality; and he thought they should take such measures as were necessary to prevent by their subscriptions the society falling into decay. Mr. Clayden, who was as well qualified to give an opinion as any man in the county, said they must have £500 to support such a society, and therefore he was glad to see the subscriptions had been fixed at half-a-guinea, as it appeared to be the opinion of practical men they should thus obtain a larger sum than if it were double the amount. With respect to Mr. Hobbs's observation as to the time of holding the meeting, he did not wish to criticise that gentleman, but he thought they should take the most popular feature in the agricultural field, and then there would be a large show of fat stock. Therefore he should like to see the meeting fixed at a time when the largest quantity of fat stock would be brought together. He moved—

"That the Chairman be requested to write to gentlemen in various parts of the county, asking for their individual co-operation with the association, and requesting that they will ascertain what support will be given to the establishment of such an association by the owners and occupiers of land in their own immediate neighbourhood; and that Mr. Burrell be invited to act under this committee until such a time as a regular secretary be appointed."

Mr. J. O. PARKER said, as to the small societies, the cause of their failure had been pointed at; the petty jealousies of these societies had led to their failure, but here they took a large field and aimed at great results. He looked on these societies as following in the steps of the Royal Agricultural Society, their objects being to confer some benefits on agriculture; and he would rather not see any fat stock, for breeding was the great object, and he believed Essex was growing into its place as a breeding county. In a remote part of this county the other day he saw some good home-bred stock stalled, a fine home bred bull in a corner of the yard, petted by the occupier, and a number of home-bred animals on the farm. This showed what was doing; and he thought that they ought to promote the breeding of stock on the Essex farms, and that as a society they should have nothing to do with a ploughing match or a wool fair, or anything of that sort. If they introduced anything connected with the labourers, they should trench on the objects of those local

societies, which they were so anxious not to infringe on. (Hear).

Mr. CLAYDEN said he thought the latter end of May would be the best time for holding the meeting, and he should say put breeding stock in the first rank; but at that period of the year much fat stock had often been held over, the weather was not too hot, and they would no doubt have a good show of fat stock at that time.

Mr. FISHER HOBBS called attention to the importance of holding out encouragement to the production of good agricultural implements. Essex had a number of small implement-makers as well as large, and they were rising up year by year, having, through the meetings of the Royal Agricultural Society, an opportunity of competing with the leviathan makers.

Mr. R. BAKER could not but think something might be done for the agricultural labourers, that they might have something for the prize-man recommended by each local Society. He thought the greatest encouragement should be given to neat stock and sheep. If they had the meeting in the summer they would have but little fat stock, if in winter but little breeding stock; but in May they would have sufficient fat stock to give *eclat* to the show, though they could not expect a great quantity. The great object, however, should be the improvement of breeding stock. In the old Society he brought the subject of breeding before the committee, for at that time he had not seen a calf weaned in the county; now breeding was carried on to some extent, and if they introduced a good breed, and good short-horns were spread over the county, they would soon see a different state of Essex breeding.

The resolution was carried.

A general committee consisting of sixty influential gentlemen was appointed.

Thanks were voted to the Chairman, which Mr. DU CANE acknowledged; and the meeting adjourned to Friday, the 26th of February.

THE TRADE AND COMMERCE OF CHICAGO IN 1857.

We again avail ourselves of the information forwarded us by the commercial editor of the *Chicago Daily Press*, in his Sixth Annual Review of the Trade and Commerce of Chicago for the Year 1857. A year of more than ordinary calamity, in which some of the old and wealthy cities on the Atlantic seaboard have been obliged to succumb to the financial crisis, but that has left this city of Chicago, which is only the growth of the past dozen years, as sound as ever in its commercial relations, and with a vigour and elasticity which promises to be equal to any and every emergency. True it is that the trade of Chicago, being dependent on the produce of the surrounding agricultural country, poured into its stores and warehouses along three thousand miles of iron road, was on a more solid basis than many of those other cities which bore the traces of the late commercial ruin. Still, we were prepared to see in its returns symptoms of the general stagnation in trade; while we find the fact to be, that the prudence displayed by the bankers and traders of Chicago, aided by their solid capital—the accumulations of the energy and successful commerce of the last twelve years—has preserved her credit, and enabled her to achieve a commanding position amongst her sister-cities of the Union. The report says:

"Though some of our country banks were forced to close their doors, and all the banks in Illinois and Wisconsin, except the Marine and the Chicago Banks of this city—which, to their honour be it said, paid the coin on demand for all their issues—virtually suspended specie payments, yet our bankers received at par the bills of all the country banks, and thus saved the business of the city from utter stagnation and ruin. The position which our bankers assumed towards our business men, and that of business men towards each other, was not one of hostility, but of mutual forbearance and support; and never, in commercial as well as in all other matters, was the motto more beautifully illustrated—'In union there is strength.'"

The consequence of this "union" was that, during the worst weeks of the panic, the shipments of wheat were one hundred thousand bushels per day, and of all cereals averaged nearly two hundred thousand bushels. By a reference to the commercial tables, we find that the exports last year, in spite of the low prices which prevailed, have not materially fallen of. They have exported more wheat, packed more beef, and shipped more cattle than in the previous season; and a large surplus is reported in the country for this (the coming) season's business. The prospects of this year are stated to be such as will far outstrip that of any previous one.

The grain trade of 1857 has been active, and, contrary to all expectation, shows but a very slight falling-off as compared with 1856, and an increase over 1855. Grain is the most important branch of the trade of Chicago. The receipts in the year 1857 was 21,856,206 bushels: this shows an advance over 1855, which was only 20,487,953 bushels, yet 1857 wanted about 3,000,000 bushels of being as large as 1856. The shipments of grain and flour, reduced to its equivalent in wheat, was, for 1857, 18,032,768 bushels, or 2,818,618 bushels less than those shipped in 1856; but it is 2,000,000 over the quantity shipped in 1855. These numbers give the general totals of all cereals; but if we look at the great staples (wheat and flour), we find that the increase of shipments of 1857 is over that of 1856. Thus, of wheat they exported 9,485,052 bushels; or, 1,147,632 bushels more than in 1856, and 3,286,897 bushels more than 1855. In flour likewise there is the large increase of 40,000 barrels more shipped than in 1856, the numbers being, for 1857, 259,648 barrels.

The provision trade of 1857 shows also an important increase over 1856; the number of cattle slaughtered in the past year being 19,127, or 4,000 over 1856. It is stated that before the scarcity of money occurred, the packers calculated on 30,000 head as being the quantity required. The quantity of live cattle shipped was 25,000, or 3,000 over the business of the previous year.

The figures given above will show our readers the importance and the rising position of this vast grain emporium. The grain trade of this prairie city, and its rise and progress, to those who have seen it in its infancy, appear a miracle. In 1838 it commenced by the shipment of 39 bags of wheat. In 1857 (not twenty years) it has attained the magnitude of over 20,000,000 bushels of all kinds of grain. Yet this is as nothing to what the position of Chicago promises at its full and future development. It is yet but in its infancy. From its situation—"the key and natural outlet of the great north-west"—it must become the mightiest interior commercial port of America. As the railways creep up still more north and west, so will the trade of Chicago increase, and that from the actual producers of the soil; so that to the merchants of the old world it must become the cheapest and best supplied market. The reviewer proudly says—

"The grain trade of Chicago, it must be remembered, too, in this connection, has a much brighter future than most people dream of. As a mere depôt for the grain trade of the East, Chicago will not long remain. The markets of Liverpool, Glasgow, Hamburgh, and the whole Continent of Europe are fed by us; and it is not natural to suppose that we will remain an inland port when a canal of about fifty miles in length will carry our ships of a thousand tons burthen laden with grain to the St. Lawrence, and thence into the

broad waters of the Atlantic. No; Chicago—the commercial emporium of the entire Northwest—will, before many years, be placed in as direct communication with Liverpool, Havre, and Glasgow, as New York now is. When this shall have been accomplished—when our railroads have reached the valleys of the Missouri, the Platte, the Big Sioux, and the Red River of the North—then will the grain trade of Chicago begin to shape itself into a legitimate magnitude and importance."

The following receipts of flour and grain, with the shipments for the four past years, will show the importance of this city as a primary grain port:

	1854.	1855.	1856.	1857.
Wheat, bush..	3,038,955	7,535,097	8,767,760	10,554,761
Corn	7,490.753	8,532,377	11,888,398	7,409,130
Oats	4,193,385	2,947,187	2,219,897	1,707,245
Rye	85,961	68,068	45,707	87,911
Barley	201,764	301,805	128,457	127,689
Total	15,011,540	17,284,648	23,050,219	19,886,536
Flour into wheat	792,875	1,203,310	1,624,605	1,969,670
Total	15,804,423	20,487,953	24,674,824	21,856,206

The following is a table showing the shipments for the past four years:

Shipments of all kinds of Grain during the past Four Years.

	1854.	1855.	1856.	1857.
Wheat, bush..	2,206,725	6,208,155	8,337,420	9,485,052
Corn	6,837,899	7,517,625	11,129,668	6,814,615
Oats	3,229,987	1,899,538	1,014,547	416,778
Rye	41,157	19,318	509	..
Barley	148,421	92,082	19,051	17,993
Total	12,364,185	15,816,718	20,501,276	16,734,438
Flour into wheat	538,135	817,095	1,081,945	1,298,240
Total	12,902,320	16,633,813	21,583,221	18,032,678

One thing only is wanted to crown Chicago as the greatest port of America; that is, a ship canal. What are its merchants and traders about, that the project is not undertaken? The St. Lawrence is the natural outlet to the world—a ship canal to the St. Lawrence would complete the fortunes of all interested in the welfare of Chicago. Is there no company to be formed to carry out this work? By the Georgian Bay and Toronto is the best route. If this were accomplished we could join the reviewer in asking—"What will its future be?" and answer—"What Nature by the commanding position she gives Chicago has destined." To the north-west are the lovely valley of the Saskatchewan and the Red River of the north. Illinois, Iowa, and Wisconsin are but new countries half developed; while Kansas, Nebraska, and Minesota have but yet commenced an existence. Ten years ago what were they? Ten years hence what will they be? The completion of a ship-canal from Chicago to the St. Lawrence would answer both questions, and open to the old world a greater and cheaper source of supply of human food than we can now even dream of, and that in a direct line of transit from the producer to the consumer.

ADULTERATION OF FLOUR.—At the Castle of Exeter, on Friday, before a full bench of county magistrates, John Manley, a miller of Erwick, near Exeter, was charged with having mixed alum with his flour for the purposes of sale. A large piece of alum, weighing a hundred pounds, and some sprouted wheat and oats with small bits of alum in them, were produced. The latter had been seized whilst in process of being ground into flour. The defendant pleaded guilty, but said that he had adopted the practice of mixing only six ounces of alum with every sack of flour, in ignorance of the law. The wheat seized had been imported from America. It was dark and sprouted; and in order that the baker might make the bread rise and be able to "draw the batch," it was necessary to mix a small quantity of alum with it. He had been in the habit of selling the flour produced from this mixture as "seconds," and when it was made into bread his family had been in the habit of eating it. The bench convicted defendant in the penalty of £20 and costs.

ENGLISH & FOREIGN CORN MEASURES, AND IRISH CORN WEIGHTS.

The English value corn by measure, the Irish by weight. The former use a measure called a quarter, containing 64 imperial gallons; the latter use a weight called a barrel, which for wheat contains 20 stones, for oats 14 stones, and for barley 16 stones, each stone 14 lbs. It is manifest, therefore, that no exact relation does exist between the English measure and the Irish weight; a practical approximation, however, is obtained, by weighing a quarter of wheat of medium character, which is actually found to be 480 lbs. avoirdupois. In the same manner a quarter of medium oats is found to be 328 lbs. avoirdupois, and a quarter of medium barley 416 lbs. avoirdupois. By this means we reduce an English quarter of wheat, oats, or barley, to barrels of wheat of 20 stones to the barrel, to barrels of oats of 14 stones to the barrel, and to barrels of barley of 16 stones to the barrel, respectively, as in the following table, in which quarters of wheat are turned into barrels of wheat, quarters of oats into barrels of oats, and quarters of barley into barrels of barley:—

Eng. qr.

of wheat, oats, or barley.	Wheat. brl.	st.	lb.	Oats. brl.	st.	lb.	Barley. brl.	st.	lb.
1 =	1	14	4 or	1	9	6 or	1	13	10
2 =	3	8	8 =	3	4	12 =	3	11	6
3 =	5	2	12 =	5	0	4 =	5	9	2
4 =	6	17	2 =	6	9	10 =	7	6	12
5 =	8	11	6 =	8	5	2 =	9	4	8
6 =	10	5	10 =	10	0	8 =	11	2	4
7 =	12	0	0 =	11	10	0 =	13	0	0
8 =	13	14	4 =	13	5	6 =	14	13	10
9 =	15	8	8 =	15	0	12 =	16	11	6
10 =	17	2	12 =	16	10	4 =	18	9	2
100 =	171	8	8 =	167	4	12 =	185	11	6

From an inspection of this table, it appears 7 quarters of wheat are equal to 12 barrels of wheat, 7 quarters of oats to 11 barrels and 10 stone of oats, and 7 quarters of barley to 13 barrels of barley.

The French value corn by the hectolitre, which is a measure containing 2 bushels 3 pecks and 1 pint imperial measure. By this hectolitre corn is principally bought and sold on the Continent. Three hectolitres make 1 English quarter of corn, and 2 gallons and 3 pints over. According to the principles before enunciated, a hectolitre of medium wheat is equal to 11 stones and 12 lbs. avoirdupois, or to half a barrel 1 stone and 12 lbs. of wheat. A hectolitre of oats weighs 8 stone and 1 lb. avoirdupois, and a hectolitre of barley weighs 10 stone and 4 lbs. avoirdupois. By this means we reduce hectolitres of wheat, oats, or barley, to English quarters, into Irish barrels of wheat of 20 stones to the barrel, barrels of oats of 14 stones to the barrel, and barrels of barley of 16 stones to the barrel, as in the following table:—

Hecto-litre.	qr.	bh.	pk.	pt.	Wheat. br.	st.	lb.	Oats. br.	st.	lb.	Barley. br.	st.	lb.
1 =	0	2	3	1 =	0	11	12 =	0	8	1 =	0	10	4
5 =	1	5	3	5 =	2	19	4 =	2	12	5 =	3	3	6
10 =	3	3	2	10 =	5	18	9 =	5	10	10 =	6	6	12
100 =	34	4	2	4 =	59	5	10 =	57	9	2 =	64	4	8

NOTE.—A Scotch boll is equal to 6 bushels, therefore 4 Scotch bolls are equal to 3 English quarters.—*Purdon's Irish Farmers' and Gardeners' Almanac.*

THE RECENT PURCHASES OF IMPROVED STOCK, BY THE EMPEROR OF THE FRENCH.

However deeply we may feel for what has befallen the Emperor Napoleon, we cannot but rejoice that an all-wise Providence has so carefully watched over him, and preserved to his country one, who has certainly displayed no ordinary power or perception as the governor of so great a people. So much has been said and written on the late dastardly attack, that it scarcely comes within the pale of our duties to enter further into this painful subject—beyond the expression of our firm belief of there being scarcely an Englishman who does not sympathise with us in our joy at Napoleon's deliverence.

Happily for ourselves and our readers, we can turn to a more pleasing picture. When the Emperor and Empress paid a visit to our shores, and became the guests of Queen Victoria, they were naturally enough made acquainted with the course of English farming, as practised not only on the Royal Farms at Windsor, but also at Osborne, and where the most approved agricultural implements and machinery of this country were exhibited before them, and the finest specimens of stock also brought specially under their notice. The Emperor of the French, with that ability which is admitted to be so characteristic of him, has now resolved to apply himself to such a course of proceeding, as shall, in an agricultural point of view, be most likely to prove of the greatest advantage to his own people. In furtherance of this object we have within this day or so had the opportunity of making an inspection of a fine collection of Short-horns, selected with great care and judgment, by Mr. Wilson, who, as many of our readers are aware, has under his care the royal farms at Windsor. We were gratified to learn that, in the purchase of this stock, together with some South Down Sheep from the Duke or Richmond and Mr. Jonas Webb, Mr. Wilson has met with the greatest possible liberality on the part of breeders generally, and that every possible facility was afforded him in carrying out the instructions he had received from the Emperor. We trust that the great national object sought to be attained herein may, for the benefit of France, be in this wise fully accomplished, and that our neighbours may ultimately possess themselves of a breed which certainly takes the very highest rank in our own country.

The stock now about leaving England has been in course of collection for some time past. It contains specimens from many of the most distinguished breeders, from whose sorts we doubt not ere long as fine a herd will be reared in France as must gradually lead to the general establishment of the breed. It would be invidious to mention specially the name of any particular breeder where all have co-operated so handsomely with Mr. Wilson in carrying out so useful an object—increasing the food of the people. The stock going out will be located at the model-farms of St. Cloud and Versailles. They will be accompanied by Mr. Knowles, the agent of Captain Gunter. His convoy is thus registered:

COWS AND HEIFERS.

Venus ..	Bought of Mr. R. Lawson
Iris	Lord Hill
Golden Drop.....	Mr. Torr
Elegant.....	Sir C. Tempest
Harp.....	Viscount Hill
Syllabub	Mr. Fawkes
Alma.....	Colonel Kingscote
Heresy	Viscount Hill
Memorandum	Mr. Torr
Ballet Dancer	Sir C. Tempest
Queen Flower	Mr Torr
Maid of Lorn	Mr. Fawkes
Lady Geraldine.....	Mr. Fawkes
Victoria.....	Mr. R. Lawson
Lady Amelia.....	Mr. J. Wood
Lady Anna	Mr. J. Wood
The Brown Kerchief ..	Mr. Fawkes
Ellen 3rd	Mr. J. Emmerson
Janetta 4th	Mr. J. Robinson
Juice.....	Mr. J. Robinson
Winter Nelis	Mr. J. Robinson
Camellia	Mr. T. Chrisp
Sweet Vaentine	Mr. Torr
Summer Sun.....	Mr. Torr
Eugenie	Colonel Towneley
Autumn Rose	Captain Gunter
Millicent	Lord Feversham
Clara.....	Mr. Thompson

BULLS.

Prince Alfred	Hired of Mr. R. Booth
Master Butterfly 4th ..	Colonel Towneley

CALVES.

In addition, there are eight calves the produce of some of the cows mentioned above.

Prince Alfred has been used at the Home Farm, Windsor. Master Butterfly 4th is a son of the renowned Master Butterfly (sold for 1,200 guineas), and from a daughter of Colonel Towneley's celebrated cow, Beauty, the winner of the first prize at the Lincoln Show of the Royal Agricultural Society.

A STATE OF TRANSITION.

The steam-plough would appear to be nearer a realization than many might suppose. The Salisbury failures are already forgotten, or satisfactorily explained. Mr. Smith, of Woolston, has now, it is said, upwards of thirty of his implements in use. Mr. Fowler still continues to work by contract; while Mr. Romaine is in better heart than ever as to the success of his scheme. The great test of such a process is becoming practicably susceptible of an application. There is to be economy in every possible way—a saving of money, labour, and time. The work, too, is to be better done, and the results proportionately greater. Mr. Smith, Mr. Mechi, or Mr. Fowler will either of them testify to a quarter more per acre, where steam-power has superseded that of horses. The improvements of late have been, in fact, so striking, that we are told to look upon the experiment as accomplished. Mr. Smith has sold his cart horses, and talks not only of what he himself, but what his "brother farmers," are doing. Mr. Fowler is yet more decisive in his dicta:—"as far as steam-ploughing was concerned, he considered his task done."

In a matter of this kind we look more especially to "the latest intelligence;" and this certainly goes far to support Mr. Fowler in what he here asserts. His more recent trial at Stirling was unquestionably a very triumphant one, backed as it was by the full premium of the Highland Society. Mr. Smith, of Woolston, again, offers us proof of equally high character, although coming, perhaps fortunately, through less public channels. Gentlemen who have worked his plan, not for an hour or two on a show day, but on their own farms and with their own men, volunteer him testimonials of its practical efficiency. Even beyond this the two most famous of all our plough-makers are directly concerned in this new branch of business. The Ransomes have Mr. Fowler's invention in their keeping; and the Howards are manufacturing Mr. Smith's implements.

There must be something in this; and both landlord and tenant may look to it a little closer than they hitherto have done. Of course it would never do for a tenant to be engaging in every new speculation brought out for his benefit, or in trying every experiment for that of other people. We believe that, as far not only as regards useful, but even promising discoveries, the farmers have of late years quite done their share of the good work. It is a serious matter, however, to ask a man to give four or five hundred pounds for a piece of machinery, or to lay out five-and-twenty or thirty pounds an acre in putting his land in order, before he is quite sure that either process may answer. This has been the case with our agriculturists. They have not treated the many plans for ploughing by steam with neglect or indifference, but have simply waited for something really practical and serviceable. It is only within the last few months that such a consummation has been arrived at.

Indeed, we never remember to have seen the subject so boldly faced as it was at the recent meeting at the Society of Arts. With one notable exception, there was not a speaker but who looked on ploughing by steam as very near its realization. The occasion was the reading of a paper by Mr. Algernon Clarke, that we give in full elsewhere. Himself somewhat of an enthusiast in the cause, Mr. Clarke still scarcely appeared to the advantage he might have done. His essay, in short, was written and sent in a year since. His able summary or history of the different processes for applying steam to the cultivation of the soil had consequently been very much anticipated—amongst others, in our own columns. His suggestions for improving the most successful of these inventions shared much the same fate—as in the instance of Fowler's plough, they have already been acted on. Nevertheless the paper will always have a value, as the impartial summing up of one who unites something of the mechanic's taste and skill with the education and the habits of the farmer. Mr. Clarke concluded by submitting a plan of his own. However this may succeed, it shows the soundness of his deductions that the very amendments he would propose have been adopted. Mr. Clarke could scarcely have desired a higher compliment.

The discussion that ensued should have been one of the most interesting of the season. The meeting embraced all the component parts for such a purpose. As we expected, from the time fixed there was scarcely a tenant-farmer present, although many far better prepared to speak to the point. There was Mr. Fowler to answer for his plough, and Mr. Smith for his. There was Mr. Romaine to tell what he was doing, and Mr. Halkett to declare what he wished to do. There was Mr. Boydell to offer his aid; Messrs. Ransome and Howard to keep the amateurs straight and fair; and Mr. Mechi to prove what cart-horses cost, and steam-ploughing *had* done. Unfortunately only three or four of these had a hearing. The discussion opened with the reading of a letter from Mr. Garrett, who "felt little improvement had been made in the art by any of the methods during the last two years," and who consequently still inclined to an undeveloped scheme of his own for a steam digger! Then Mr. Mechi dwelt on the marked superiority of ploughing by steam:—"There was a difference in the crop of wheat of at least a quarter per acre in its favour." The excellence of Fowler's work, the money (upwards of ten thousand pounds) spent in perfecting Romaine's machine, and the advantage of fork-digging, formed the chief features in the ex-sheriff's address. Mr. Ransome, also, bore testimony to the results of Fowler's method of ploughing; the superiority of the spade to the plough, and the damage done by the horses' feet. He was followed in turn by a Mr. Newton, who declared himself "not a practical agriculturist," and who did not appear to be a practical mechanic. He might well have left the discussion to those so much better qualified to carry it on. Mr. Fowler "ventured to say the system he had introduced was a step in the right direction. There could be no question that it was really a practical plan, inasmuch as it performed the ploughing at half the cost of horse-power, and the work was better done. Seven acres of sandy soil in the neighbourhood of Ipswich, ploughed by steam, had a yield of a quarter per acre more in crop." After admitting the superiority of hand spade cultivation over even steam ploughing, and bearing witness to what Mr. Boydell had done for steam traction, Mr. Fowler asked, "Who was to try all these experiments? Were the inventors to bear the whole brunt of that which was in fact a national benefit? The landlords hitherto had done little. The Royal Agricultural Society had given no help. He could only state that the trial of his system at Salisbury was appointed to take place on a steep hill, resembling

the roof of a house, and the decision arrived at was that the steam plough would not answer. Notwithstanding all this, he was prepared to prove that he could plough at half the cost of horse power. It was plain they would get no assistance from the public or from the landed proprietors, who would, after all, derive the greatest benefits in the improved rental of their estates. As far as steam ploughing was concerned, he considered his task was done; but it was for such men as Messrs. Romaine and Boydell to carry their experiments further in another direction, and he was strongly of opinion that the public at large ought to help them in their work."

Mr. Smith, of Woolston, in answer to this, would receive no aid—neither from a society nor an individual—but stand or fall on his own merits. Mr. Smith's speech, which promised at first to be amusing enough, ended by becoming insufferably tedious. With an unpardonable want of discretion he fairly talked his audience out of the room; and when he came to reading long letters in his own favour, the effect produced was precisely similar to that of reading the Riot Act—"the crowd at once dispersed." We regret this the more, as Mr. Boydell, Mr. Romaine, and Mr. Halkett should all have had the opportunity, and were all, we believe, prepared to say something. The Society, however, has a very excellent rule of closing the proceedings at ten o'clock; and at a few minutes past that hour Mr. Fairburn left the chair, with Mr. Smith still, of course, in possession.

As the Chairman himself said, we are now clearly "in a state of transition as regards the cultivation of the soil;" while the result of this meeting would point to the more general introduction of steam power in this wise:—The union of the common portable farm engine with either Fowler's or Smith's system.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

A MONTHLY COUNCIL was held on Wednesday, the 3rd of February: present, Lord BERNERS, President, in the Chair; Lord Southampton, Lord Portman, Lord Feversham, Right Hon. the Speaker, Hon. William George Cavendish, M.P., Sir Watkin W. Wynn, Bart., M.P., Sir Archibald K. Macdonald, Bart., Sir John V. B. Johnstone, Bart., M.P., Mr. Dyke Acland, Mr. Raymond Barker, Mr. Barnett, Mr. Barthropp, Mr. Bramston, M.P., Mr. Brandreth, Mr. Caldwell, Colonel Challoner, Mr. Druce, Mr. Brandreth Gibbs, Mr. Hamond, Mr. Fisher Hobbs, Mr. James Howard, Mr. Hudson (Castleacre), Mr. Jonas, Mr. Lawes, Mr. Lawrence, Mr. Milward, Mr. Pain, Mr. Pope, Mr. Sillifant, Mr. Robert Smith, Mr. Banks Stanhope, M.P., Mr. Thompson, Mr. Torr, Colonel Towneley, Mr. Turner (Barton), Professor Way, Mr. Jonas Webb, and Mr. Wilson (Stowlangtoft)

The Rev. Henry John Ingilby, of Ripley Castle, Yorkshire; and the Rev. Archer Clive, of Whitfield, Herefordshire, were elected governors of the Society.

The following new members were elected:

Astbury, John Steadman, Oulton House, Milwich, Staffs.
Bates, George, Blackhall Hall, Wickham-Market.
Bushel, Christopher, Hinderton, Neston, Cheshire.
Butterfield, Rev. G. B. B., Great College-street, Westminster.
Craue, James, Shrawardine, Shropshire.
Davies, D. R., Mere Old Hall, Knutsford, Cheshire.
Dodweil, Joseph, Manor Farm, Long Crendon, Thame.
Gould, John, Hyde Hall, Denton, Lancashire.
Grantham, Stephen, Paragno, New Kent-road, Surrey.
Lloyd, John, Belsize, Hampstead, Middlesex.
Malcolm, Matthew, Manor House, Kineton, Warwickshire.
Neame, Percy B., Solestreet House, Feversham, Kent.
Norris, John, Pully, Shrewsbury.
Paxton, Robert, Marsh Farm, Lower Winchenden, Aylesby.
Paddock, Henry, The Trench, Ellesmere, Shropshire.
Peel, Edmund, Bryn-y-Pyss, Wrexham, Denbighshire.
Shackleton, John, Leeds, Yorkshire.
Smith, Michael, Cefn, Isla, Usk, Monmouthshire.
Thomas, Rev. Lewis, St. Hilary, Cowbridge, Glamorgan.
Thomas, Thomas, St. Hilary, Cowbridge, Glamorganshire.
Warner, Charles Borham, Jewin-crescent, Aldgate, London.
Williams, Rev. Edm. Turberville, Mount Balam, Chepstow.
Villiers, Hon. Fred. W. C., Sully Hall, Northamptonshire.
